On the 12th, Capt. Benjamin Huger planted heavy batteries there and at three other places, to range the south and west of the hill (the only accessible portions), on which an assault had been determined; their fire gradually silenced that from Chapultepec, breached the defenses and caused much loss. About 8 A.M. on the 13th Scott launched two assaulting columns: Brig. Gen. Gideon J. Pillow on the west, from Molino del Rey through the cypress grove, supported by Maj. Gen. William J. Worth; Brig. Gen. John A. Quitman against the south from the heights of Tacubaya, where Scott had his headquarters, supported by Brig. Gen. Persifor F. Smith. Preceded by the pioneer companies with ladders, axes, picks, and crowbars, and under a plunging fire, they surmounted all obstacles, cleared the approaches, broke through the walls, climbed the heights, entered the castle gates, and, having cut off retreat by the northwestern road to Mexico City, captured the entire garrison. The approaches and castle had been mined, but the defenders waited too long before exploding the mines and failed. The next day the United States Army overcame all remaining resistance and entered the capital. Their loss in these three days was 863 killed and wounded. The Mexican loss was unknown, but certainly as heavy, and included several brilliant and gallant officers; and 823 prisoners were taken, including three generals, one the commandant of the academy. Among the United States officers prominently engaged were many afterward distinguished in military and civil life.

Consult Bancroft, H. H., *History of Mexico*, vol. 5 (San Francisco 1885); Wilcox, C. M., *History of the Mexican War* (Washington, D.C., 1892); Henry, R. S., *Story of the Mexican War* (Indianapolis 1950).

CHAR or **CHARR**, chär, a genus of fishes (*Salvelinus*) found plentifully in deep lakes of Great Britain and the northern European continent as well as in North America. Anything stated about them must be considered provisional, since they are still the subject of great indecision specifically. The best-known varieties of char are the American brook trout, a variety found in the Rangeley Lakes, Maine, very similar to the European char, and the much-discussed Arctic char, which is still being studied. They have the usual shifting and beautiful colors of the other trout and are all good eating. They range in size from a more usual weight of under 1 to 35 pounds.

CHRISTOPHER W. COATES.

CHARACTER, a word originally denoting a die for stamping coins as well as the device stamped upon them. The word comes directly from ancient Greek. In familiar usage its meaning became broadened to include a device for marking or writing, such as a stylus, and the symbols produced through its use. In contemporary English the word retains this sense, and it may be used to allude to letters of the alphabet or other signs in handwritten or printed language. By the 5th century B.C. character had acquired the meaning of the unique, differentiating aspects of an individual, a nation, or a form of literary expression. Such writers as Herodotus and Aeschylus employed it in this broad sense. The classical rhetoricians and literary critics used the word to designate various literary forms and personages in literature. This ancient connotation has been retained in modern usage. Thus, one speaks of the characters in a Shakespearean play, for example, or of "characters from the pages of history." There is justification for using the word character as a synonym for personality.

Implied in the ancient Greek denotation of the word is an emphasis upon something which is unique. Obviously, to thwart counterfeiters the Greeks took utmost care with their *characters*—namely, the dies used to mint coins and the devices on the coins. This connotation doubtless led to the use of the term in such literary characterizations of types as that attributed to Theophrastus (d. about 287 B.C.) and introduced into European literature as a popular literary form by Jean de La Bruyère (1687). A "character" was an interesting type of individual described in an entertaining, concise essay. In more recent years (1912-1932), the Boston writer Gamaliel Bradford revived this literary convention in his "psychobiographies" or character sketches of eminent persons; and Edgar Lee Masters created fictitious characters in the stanzas of his *Spoon River Anthology*.

The Christian theologians employed the word in a different sense. St. Augustine, for instance, mentions the unique characters or signs which the soul receives as the individual goes through the various rites of the church. St. Thomas Aquinas established this use when he wrote of *character baptismatis* and *character confirmationis*. One achieves character by observance of religious practices, and the soul gradually takes on new

attributes as a result. The older connotations still continued in daily speech and secular writing, and the word acquired many different meanings.

Immanuel Kant invested the word character with an ethical or religious meaning. In his *Kritik der reinen Vernunft* (1781) he distinguished between empirical character (that which follows the natural laws of cause-effect and which is determined) and intelligible character (that which is not subject to causal laws and which is free to choose). In his *Anthropologie* (1798) he describes physical character (the body and its disposition or temperament) and moral character (that nonmaterial aspect of man which he may achieve through ethical striving). He proposed that the term character be limited in use to designate nothing but what he referred to as moral character.

Modern writers on biology, however, often use the word to designate physical traits or characters. Lamarck (1744-1829), for instance, wrote about the possibility of hereditary transmission of acquired characters. August Weismann (1834-1914), on the other hand, upheld the view that congenital characters (in this restricted sense of the word) are biologically inherited but that acquired characters cannot be transmitted. Contemporary writings on genetics often contain allusions to Mendelian characters such as white forelock or webbed fingers.

In ethics and in educational psychology the word connotes an evaluation of personality in terms of some code or standard of moral principles. Thus, when a person's character is evaluated, the judge must take a moralistic, judgmental point of view. The Christian and the Hebrew theologians find in the Scriptures those standards or norms whereby they are able to make evaluations of the moral worth or character of human beings. In legal evaluations the court makes use of precedents or of codes to attempt to make objective, impartial judgments about the character of a person on trial. Witnesses may be called to testify as to his character. In this frame of reference, the evaluation and the definition of character may become ambiguous and subjective. Nevertheless, there does seem to be a need to have valid standards whereby character may be evaluated. A major objective in educational work, religious and secular, is the furtherance of character development. The principal difficulty in secular endeavor is that of finding a valid, tenable, just code or norm for evaluations.

The popularity of cultural anthropology as a field of study has disseminated the concept of moral relativism. That means that judgments may be made only when the total frame of reference is taken into account as it exists in the particular society or subculture. Actions which indicate a nobility of character in one age may be quite impossible in another age. Similarly, there are no objective codes whereby any conduct may be evaluated in terms of character. Needless to say, this concept has aroused indignant replies from ethically and religiously oriented persons.

Studies of juvenile delinquency have brought into attention the concept of determinism. This, like the concept of moral relativism, is a disturbing view to those who uphold the belief in moral absolutes and in freedom of choice. In the Kantian sense of the term, character implies a negation of both of these concepts. The individual must be judged by his actions, and in these

matters he has freedom of choice. If he has a low character, he chooses low goals; if he is noble in character, he chooses lofty goals. Obviously, the adjectives "low" and "lofty" imply an acceptance of moral absolutes. Complex questions arise in the study of the theory of ethics, and these are but two relatively simple examples.

In 1928 the first of a series of important research investigations dealing with character was published. Known as the *Character Education Inquiry*, these reports describe the manner in which various character traits (for example, honesty) were defined, the techniques devised to measure them, and the results of an intensive program of testing. Hartshorne, May, and others (see bibliography) tested more than 11,000 pupils from 6 to 16 years of age. Some representative findings are of interest here: (1) attendance at Sunday schools of the conventional type and memberships in youth organizations which are designed to foster character development have very little relation to scores on honesty-deception tests; (2) much inconsistency is found among measures of honesty-deception, pupils honest in one situation cheating in another; and (3) there is a significant relationship between the scores on these tests and the socioeconomic status of the home, pupils from privileged homes having better scores than those from marginal homes. This objective inquiry into the nature of character has stimulated a considerable amount of research by other investigators in many parts of the world.

Educators in American secondary schools have accepted as one of their cardinal objectives the promotion of ethical character in their pupils. A large amount of thought is being given to the methods whereby this objective may be attained. There is widespread recognition of the necessity to foster growth in moral character. Important developments have been made in the field of religious education by such reformers as Luther A. Weigle, of the Yale Divinity School. School and college administrators are frank in their statements about practices which may militate against this objective (such as commercialized, subsidized athletics in American colleges). New techniques in character education are supplanting traditional reliance upon exhortations, forbidding and threatening, and overuse of corporal punishment. A great amount of research is still needed in order to work out intelligent, effective methods in this field.

PHILIP LAWRENCE HARRIMAN,

Professor of Psychology, Bucknell University.

CHARACTERISTICS, the title of a volume by Anthony Ashley Cooper, 3d earl of Shaftesbury, consisting of six treatises collected and published in 1711 under the full title *Characteristics of Men, Manners, Opinions, and Times*. They comprised *A Letter Concerning Enthusiasm*; *Sensus Communis: An Essay on the Freedom of Wit and Humour*; *Soliloquy, or Advice to an Author*; *An Inquiry Concerning Virtue*; *The Moralists: A Political Rhapsody*; and *Miscellaneous Reflections*. Two more essays appeared in posthumous editions. The book is the

principal lifework of a cultivated and high-minded Whig nobleman, who, debarred by ill health from a public career, dedicated himself to the study, practice, and inculcation of moral philosophy. Writing for a skeptical and rationalizing age, Shaftesbury is primarily concerned to show that goodness and beauty are not determined by revelation, authority, opinion, or fashion, but by the essentially constant and inalterable nature of man and things.

From his *Philosophical Regimen*, first published in 1900, it appears that he had reached his own convictions by a rigorous process of self-examination and self-discipline in imitation of his favorite classical masters, Epictetus and Marcus Aurelius. In common with the Stoics of antiquity and the Deists of his own time, he finds in the general harmony of the universe objective evidence of a supremely benevolent Mind, to whose purposes it is the part of every man's wisdom to conform. In distinction from Thomas Hobbes, he holds that human society was not created by a contract but was inherent from the first appearance of man in the world, in the natural and necessary relations of male and female, parents and offspring. In distinction from John Locke, the supervisor of his early education, he denies that all our ideas are derived from experience, insisting that our conceptions of right and wrong are, if not precisely innate, yet predetermined and appointed for us by our physical and mental constitutions and by our destiny as social beings. To study the "natural" law of one's own being and of one's relations to one's fellow beings and to the universe is essential, Shaftesbury persuades us, to the character of a fine gentleman and a man of sense. "To philosophize, in a just signification, is but to carry good breeding a step higher. For the accomplishment of breeding is to learn whatever is decent in company or beautiful in arts; and the sum of philosophy is, to learn what is just in society and beautiful in Nature and the order of the world."

This passage suggests what is perhaps the most personal aspect of Shaftesbury as a moralist—his aesthetic sensibility, his identification of the good with the beautiful, his insistence that conduct is a fine art with principles analogous to those of music and sculpture, and to be relished by every gentleman of taste. To a public beginning to take pride in its civility, in its tolerant and equable temper, in its devotion to common sense, Shaftesbury's studious ease and serenity appeared admirable, his urbanity worthy of emulation, his suave irony delicious, and his benevolent and optimistic metaphysics an acceptable antidote to the egoism of Hobbes and the pessimism of the theologians. He attained in the 18th century a wide reputation in England and abroad, influencing such men as Gottfried Wilhelm von Leibniz, Johann Gottfried von Herder, Benjamin Franklin, Voltaire, Denis Diderot, baron de Montesquieu, Alexander Pope, Francis Hutcheson, David Hume, and Joseph Butler. In the reaction which followed the French Revolution his political and religious liberalism was disparaged as atheistical and revolutionary; whereupon it was discovered that his style was artificial and pedantic. In the 20th century there have been some attempts at a critical restoration, notably in J. M. Robertson's edition of the *Characteristics*, 2 vols. (London 1900), and in Benjamin Rand's *The Life (by his Son)*. Unpublished *Letters and Philosophical Regimen of the Third*

Earl of Shaftesbury (London 1900), where Shaftesbury is ranked with Epictetus and Marcus Aurelius as one of the "three great exponents of stoical philosophy."

STUART P. SHERMAN.

CHARACTERS (Fr. *CARACTÈRES*), a collection of Jean de La Bruyère's reflections on human nature and conduct and of "portraits" of different types of character or varieties of moral development, studied with patient and penetrating observation and drawn with extraordinary skill in a few precise, significant and revealing lines. They are distributed over 16 chapters: heart, society and conversation, material possessions, the city, the court, persons in high station, the sovereign or the state, man, judgments, fashion, certain usages, the pulpit, the strong minded. They derive in part from the *Characters* of Theophrastus and appeared for the first time (1688) as an appendix to a translation which La Bruyère had made of that work, modestly hiding behind the Greek even in the title: *The Characters of Theophrastus, Translated from the Greek, Together with the Characters and the Manners of this Century*. They also continue the "portraits" long popular in the novels of the time and in the literary recreations of certain salons. But these portraits are no longer complimentary and flattering, as those had been. Instead, they insist pitilessly on the unlovely realities of motive that too often lie behind the smiling mask of manners. La Bruyère was a sharp-eyed observer of the brilliant society of court and salon. Indeed, there were many complaints from those who saw themselves in the satiric pictures which he drew, though he disclaimed the intention of painting particular persons. His view of human nature is less embittered than that of his great contemporary the Duc François de La Rochefoucauld in the *Maxims*, but it is stern and hard, lacking in pity and tenderness. To the composition of his *Characters* he brought a rare command of the French language, which he cultivated with infinite pains, and the judgment of Marie-René Valléry Radot is often quoted with approval: "If you wish to take an inventory of the riches of our language, if you wish to know all its ins and outs, its movements, its figures, its resources, there is no need to have recourse to a hundred volumes; read, reread La Bruyère."

The *Characters*, by the progress which they mark in the art of psychological observation and moral characterization, also contributed substantially to the development of the novel, and their influence was clearly seen soon in English writers, such as Joseph Addison and Richard Steele. Several translations, one by Nicholas Rowe (1709), were made, but none, however, is current. The standard edition is that of M. G. Servois in the series of the *Grands Écrivains de la France*, 3 vols. (Paris 1865-1868; 3d ed., 6 vols., Paris 1922).

ARTHUR G. CANFIELD.

CHARADE, shā-rād', a syllabic enigma or riddle to be solved by guessing each syllable of a word separately as an individual word, then guessing the whole. This may be done in writing, a method in which the French have excelled, or more popularly as a guessing game for a social gathering. The company choose sides, one side becoming actors, the other audience. In either

pantomime or dialogue the actors proceed to give a short scene in which each syllable is acted or spoken, finally acting out the whole word. If the audience guess the word correctly, they in turn become actors.

CHARADRIIFORMES, kā-rād-rī-ī-fōr'mēz, an order of birds, most of whose members live on or near the ocean or other bodies of water. The order consists of three main subgroups or suborders: (1) Charadrii, or the shore birds, such as plovers, sandpipers, and avocets; (2) Lari, or the gulls, terns, and skimmers; and (3) Alcae, or the auks, puffins, and murres.

CHARAS. See **HEMP**.

CHARCOAL, chār'kōl, a black, solid, non-lustrous residue, or amorphous carbon, from vegetal or animal substances; or a coal made by charring wood in a kiln or retort from which air is excluded. Where it is a hardwood distillation product, it has 84 per cent fixed carbon, 14 per cent volatile matter, 2 per cent ash, and a trivial amount of sulphur. Charcoal is used for fuel—in blast furnaces to manufacture charcoal iron, for domestic and institutional purposes, for metallurgical fuel other than in the blast furnace, and for nonferrous metal works. In the past its largest industrial use was as a fuel in connection with the making of charcoal iron. In the 20th century this use has declined to a minimum percentage. Since 1930 the largest single outlet for charcoal has been for use in the United States.

Charcoal produces a quick, hot fire. The glowing coals developed by burning charcoal are especially suitable for broiling and roasting foods in cafés, restaurants, trains, homes, and outdoor grills. Because of its efficiency as a cooking fuel, it is admirably adapted for use by persons of modest incomes: metropolitan New York City consumes some 3 million bushels annually. It is a popular fuel in the Southern states. As a chemical it is employed in the manufacture of carbon bisulphide, carbon tetrachloride, sodium cyanide, and similar substances. It is used in mixed feeds for poultry and livestock and is an absorbent for vapors and a clarifying, deodorizing, and decolorizing agent.

Activated charcoal is becoming increasingly important in treating municipal water supplies and can control offensive odors from sewage sludge beds. Impurities which make for objectionable tastes, odors, and colors, in oils, sirups, beverages, medicinal products, and foods, can be removed by the use of charcoal. In European countries it is successfully employed as a fuel to produce motor gas for automobiles, buses, and trucks.

An estimated 350,000 tons of charcoal are produced annually in the United States. Latest figures compiled by the Bureau of the Census show, for an eight-month period, consumption of 339,680 cords of hardwood and softwood in making United States charcoal. See also **CARBON**.

M. EDMUND SPEARE,
Educational Director, Bituminous Coal Institute,
National Coal Association.

CHARCOAL DRAWING. See **ART DRAWING**.

CHARCOT, shâr-kô', Jean Baptiste Étienne Auguste, French explorer: b. Neuilly-sur-Seine, France, July 15, 1867; d. at sea off Iceland, Sept. 16, 1936. He was an interne at the Hospital of Paris from 1890 to 1894 and was at the same time an investigator at the Pasteur Institute. In 1896-1898 he headed the clinic of the faculty of medicine at the University of Paris. In 1903-1905 and again in 1908-1910 he was leader of expeditions to the Antarctic. He mapped Graham Land and its islands, in 1910 discovered Charcot Land (an island) which he named for his father J. M. Charcot (q.v.). He published official accounts of both expeditions, also "*Pourquoi Pas?*" dans l'*Antarctique* (1912), *Autour du Pôle Sud* (1912), *Christophe Colomb vu par un marin* (1928).

CHARCOT, shâr-kô', Jean Martin, French physician: b. Paris, Nov. 29, 1825; d. Morvan, Aug. 16/18, 1893. He received his medical degree in Paris in 1853 and was appointed to the Central Hospital Bureau. He later became professor of pathological anatomy and in 1862 was connected with Salpêtrière. His specialty was in the treatment of nervous and mental diseases, and he performed many curious and successful experiments in hypnotism and mental suggestion. The name *Charcot's disease* has been applied to cerebrosplinal sclerosis. In 1880 he founded a clinic at the Salpêtrière for the treatment of nervous diseases. His most important work is *Leçons sur les maladies du système nerveux* (1873, Eng. tr. 1877). All his published works, which include treatises on mental disorders, hysteria, and the ills of old age, were collected in *Oeuvres complètes*, 9 vols. (1886-1890).

CHARD, Swiss. See BEET—Swiss Chard.

CHARDIN, shâr-dân', or shâr'din, Jean (later, SIR JOHN CHARDIN), French Oriental traveler: b. Paris, Nov. 26, 1643; d. London, Dec. 25, 1712. Before he had reached his 22d year his father, a jeweler, sent him to the East Indies in order to buy diamonds. Chardin lived six years in Ispahan, where he was less engaged in mercantile business than in profound studies and scientific researches, making use of his connections at court for collecting the most authentic information of the political and military state of Persia. He collected the most valuable materials relating to antiquities and history. In 1670 he returned to France, but again left France for Persia, in 1671, taking with him a considerable quantity of precious stones artistically set, exquisitely worked jewelry, etc. He spent 10 years partly in Persia and partly in India. In 1681 he arrived in London, when he received the honor of knighthood. He published the first volume of his *Journal du Voyage . . . de Chardin en Perse et aux Indes Orientales* (London 1686) which was concurrently followed by an English translation. The other volumes were about to follow, when he was appointed minister plenipotentiary of the king of England to the States-General of Holland and agent of the English East India Company to the same.

In 1711 two editions of his *Travels* appeared in Amsterdam as complete works. He soon after returned to England. The exactness and truth of his statements and the extent of his knowledge, have been confirmed by all succeeding travelers, and have been serviceable to Gibbon, Helvetius, and Montesquieu. The best edition of Chardin's

Travels is that by M. L. Langles in 10 volumes (Paris 1811).

CHARDIN, shâr-dân', Jean Baptiste Siméon, French painter, b. Paris, Nov. 2, 1699; d. there, Dec. 6, 1779. His father was a carpenter. The young Chardin received his first instruction from Pierre Jacques Cazes and had practical experience in executing minor portions of pictures of fashionable painters. His first independent work was a sign for the office of a surgeon. In 1728 on the occasion of a religious procession, he exhibited in the open air two pictures, one of which, *The Skate*, is now in the Louvre. He was already a master of still-life, the genre which was to be his principal occupation throughout his life. He was extremely conscientious, never beginning a new picture until the one preceding it was finished, and unceasingly consulting the object he was representing in order to be sure that his effect was true.

Chardin was twice married, and the fact is not without importance when we consider the character of the man as reflected in his art. He was "good and modest" and the delightful glimpses of family life that he has noted in his pictures are surely a result of the conditions in his own home. Of his two children the son Pierre, gave promise of becoming a painter of merit, but died prematurely at 37 years of age. Chardin was received as a member of the Académie de Peinture in 1728, and became its treasurer in 1755.

In 1757 the king installed Chardin in an apartment in the Louvre where the painter spent the rest of his life. Diderot tells us that Chardin had a great understanding of art and could recognize it in others. The observation is certainly borne out by the fact that he was one of those who voted an encouragement to the young Jacques Louis David, who was to bring in a style of painting so different from his own. He was a wise teacher, Alexandre Evariste Fragonard being a pupil of his before he went to study with François Boucher, and it was to his first master that he owed the best of his instruction. While Chardin's pictures like the exquisite *Pourvoysen* or *Le Bénédicité* at the Louvre and the innumerable still-life pieces might seem at first to suggest the Dutch school, he is in reality akin to the Hollanders only through the fortuitous similarity of his subjects. He is of the Latin tradition and his color and his idea of light—a matter to which he gave great attention—come from the earlier Frenchmen, with their Italian heritage. The composition of Chardin's work is also far removed from the Dutch—though one man of the latter nation must have appeared sympathetic to him, Vermeer of Delft. Even the latter, however, if he is easily Chardin's peer in the matter of light, is not to be placed beside him as a colorist. From the gentle palette, so gay and so harmonious, the best influence has gone forth to the French colorists ever since, and not even Delacroix can make us forget the indebtedness to Chardin of such painters as Cézanne, Renoir, and Matisse. He was very happy in the portrayal of children, as in *Boy Blowing Soap Bubbles* at the Louvre, and the excellent likeness of Rameau d'Alembert and Sedaine. From 1765 to 1769 he painted a series of decorative panels for the

castles of Choisy and Bellevue, of which the *Attributes of the Sciences, Arts and Music* are now in the Louvre. Examples of his work are in Stockholm, Leningrad, Vienna, the Metropolitan Museum in New York, and other museums. The great treasury of it remains in the Louvre.

Consult Pilon, Edmond, *Chardin* (Paris 1909).

CHARDON, shär'd'n, village, Ohio, and seat of Geauga County; altitude 1,230 feet; 25 miles northeast of Cleveland; on the Baltimore and Ohio Railroad. Office supplies, small rubber goods, and maple wood and maple sugar products are manufactured. The Geauga County Maple Festival is held here every spring. Government is by mayor and council. Pop. (1940) 2,001; (1950) 2,478.

CHARDZHOU, chär-jö'öö, city, Turkmen SSR, Asia, in Chardzhou oblast, on the Amu Darya. It is a transportation center. Cotton ginning and milling, silk spinning and karakul processing are the chief industries. Pop. (1939) 54,739.

CHARENTE, shä-ränt', inland department, France, formed chiefly out of the ancient province of Angoumois and deriving its name from the river Charente, by which it is traversed; area, 2,306 square miles; capital, Angoulême. It is in general uneven, with hills covered with chestnut trees, sandy plains, and meadows. The principal rivers are the Charente, joined by the canal of Poitou with the Vienne, Tardoire, Bandiat, Touvre, and Né. The wines of the department are of inferior quality and in little request for the table; but they yield the best brandy in Europe. The celebrated cognac brandy is made in the districts of Champagne, Cognac, Jarnac, Rouillac and Aigre from a grape which yields a white wine. The red wines furnish an inferior brandy, without the bouquet that distinguishes the genuine cognac. The winegrowers themselves carry on the distillation, each estate being furnished with stills and the necessary apparatus. Excepting brandy and paper, the manufactures of the department are inconsiderable, consisting of sack-making, cloth, cordage, hats, corks, naval guns, leather, gunpowder, flour and earthenware. The paper made at Angoulême is said to be the best in France. The department is divided into three arrondissements, Angoulême, Cognac, and Confolens. Pop. (1936) 309,279; (1946) 311,137.

CHARENTE, a river, France, rising in the department of Haute-Vienne; flowing west and emptying into the Bay of Biscay, about 10 miles below Rochefort, opposite the Ile d'Oleron; length, 225 miles. It gives its name to two departments, Charente and Charente-Maritime.

CHARENTE-MARITIME, mä-rë-tëm', until 1941 **CHARENTE-INFÉRIEURE**, än-fä-ryür', department, France, on the west coast, bounded on the north by the department of the Vendée, and on the south by Gironde; area, 2,792 square miles. It comprises parts of the former provinces of Aunis, Saintonge, and Poitou. The principal rivers that traverse or bound the department are the Charente, Gironde, Seudre, Boutonne, and Sèvre-Niortaise—all of which are navigable, as well as the canal of Brouage and that between Niort and Rochelle. The soil is fertile and well cultivated; and a considerable portion planted with vines. The soil produces hemp, flax, saffron, oats, wheat, maize, rye, potatoes, and fruit. The pas-

tures are good and well stocked with cattle, horses and sheep. Along the coast are extensive salt marshes. The industries include the manufacture of salt, brandy, machinery, porcelain and faience ware and oyster and pilchard fisheries. The department is divided into four arrondissements, and the chief harbors are those of Rochefort and La Rochelle; the latter town is the capital of the department. Pop. (1936) 419,021; (1946) 416,187.

CHARENTON-LE-PONT, shä-rän-tôn'l-pôn', commune, France, in the department of Seine; situated about a mile to the southeast of Paris, with which it is connected by rail; at the confluence of the Marne with the Seine. It has numerous mercantile and manufacturing establishments, including boat building, piano making, and porcelain and rubber goods. The stone 10-arched bridge across the Marne used to be considered as the key to Paris on this side; hence the memorable attacks upon it both in the civil wars of France and in those with foreign enemies. Pop. (1946) 21,457.

CHARES, kä'rëz, Athenian general through whose incapacity the Thracian colony was lost to Athens during the Social War in 358-356 B.C., and who exposed his country to the designs of Persia, by entering for mercenary purposes the service of the revolted satrap, Artabazus. Although recalled in disgrace, Chares was sent in 349 to the aid of Olynthus, and again he returned without having achieved anything. In 340 he commanded the army sent to Byzantium against Philip, again gave evidence of his incompetency, was replaced by Phocion, but once more invested with the supreme command. In 338 the fatal issue of the Battle of Chaeronea seems to have been mainly due to his ignorance. He was noted for his athletic figure, his profligacy, and his unscrupulous recklessness.

CHARES, Greek sculptor, a native of Lindus, Rhodes, flourished toward the close of the 3d century B.C. He was a pupil of Lysippus and the sculptor of the Colossus of Rhodes, one of the seven wonders of the world. A representation of the Rhodian sun god erected in commemoration of the successful defense of Rhodes against Demetrius Poliorcetes (305-304 B.C.), the colossus stood about 120 feet high. It was carved about 280 B.C. but later destroyed by earthquake.

CHARGE, in heraldry, one of the bearings. This may be one of the ordinaries, as they are called, the straight line bearings, as fess or chevron or a much more elaborate figure, as the representation of an animal or the head of one. Sometimes the charge is imposed upon another charge.

In *gunnery*, charge signifies the quantity of powder used at one discharge of a gun.

In *military tactics*, charge is the rapid advance of infantry or cavalry against an enemy, with the object of breaking his lines by the momentum of the attack.

CHARGE D'AFFAIRES, shär-zhä' dä-fär', a representative of a country at a less important foreign court, inferior to an ambassador, a minister or resident minister, to whom is entrusted all matters of diplomacy. He is accredited not to the sovereign, but to the minister for foreign affairs of a foreign power,

and he holds his credentials only from the minister for foreign affairs of his own country. The title is also given to the officer placed in charge of an embassy or legation during the temporary absence of the ambassador or minister plenipotentiary.

CHARGE OF THE LIGHT BRIGADE,

The, a celebrated poem by Alfred, Lord Tennyson (q.v.). Written to the meter of Michael Drayton's *Ballad of Agincourt*, it was first published in the *Examiner* in 1854. It appeared in a quarto edition in 1855, and in octavo, under the title *In Honorem*, in the following year. The line "Some one had blundered," deleted in the first edition, was restored in the second edition.

Tennyson drew his inspiration from an account in the London *Times* of the remarkable charge by the Light Brigade at Balaklava on Oct. 25, 1854, during the Crimean War. In the attack on Balaklava by the British and French forces, the Russians had been forced back by the 93d Highlanders. Col. Richard Airey (later Lord Airey), the quartermaster general, then sent Capt. Lewis Edward Nolan, his aide-de-camp, with a written order that the Light Brigade, a cavalry contingent commanded by the 3d earl of Lucan, was to charge along the southern line of heights and drive the Russians from the Turkish batteries. The 7th earl of Cardigan, to whom Lord Lucan transmitted the order, could not see the Russian position from where he was stationed, and believed that he was to advance down the valley in front of him. Nolan was killed just as he perceived the wrong direction the brigade was taking and was endeavoring to set it right. Cardigan headed straight for the Russian guns, "into the jaws of death," and the result was that, of 673 mounted men, 247 were killed or wounded within 20 minutes. The 1st Baron Raglan, British commander in chief, angered at the error and the grave losses sustained, had Lucan recalled.

CHARING CROSS, chār'ing, London, England, a triangular piece of roadway situated at Trafalgar Square. An explanation for the name is that in the 13th century a small village known as Cherringe or Charing was located there. When Eleanor of Castile, queen consort of Edward I, died at Harby, Nottinghamshire, in 1290, her body was brought to Westminster Abbey for burial, accompanied by the king. He erected a memorial cross at each place where the funeral party rested. Charing Cross was the last of probably 12 crosses erected; completed in 1294, it cost £950, with stone from Caen and marble from Dorsetshire. The original cross was destroyed in 1647 by edict of Parliament, and some of the stone is said to have been used to pave Whitehall Palace. A later cross was erected in 1863 in the yard of the Charing Cross Station.

CHARIOT, a vehicle used in ancient times for pleasure or war. In Greek mythology its invention is ascribed to the goddess Athena, while Virgil attributed it to Erichthonius, a mythical king of Athens who is said to have appeared at the Panathenaic Festival in a chariot drawn by four horses. The ancient chariot had only two wheels, which revolved on the axle. The pole was fixed at its lower extremity to the axle, and at the other end was attached to the yoke, either by a pin or by ropes. The Greeks and Romans

seem never to have used more than one pole, but the Lydians had chariots with two or three. In general, the chariot was drawn by two horses. Such was the Roman biga, but we read also of a triga, or three-horse chariot, and a quadriga, or four-horse one.

In ancient warfare chariots were of great importance. The 900 iron chariots of Sisera are described as giving him a great advantage over the

Roman chariot, bronze. Courtesy of Metropolitan Museum of Art.

Israelites (Judges 4:3, 13), and the Philistines had 30,000 chariots in their war against Saul (I Samuel 13:5). The relief sculptures of ancient Egypt show that chariots formed the strength of the army, and there are numbers of representations extant of Assyrian chariots, which resembled the Egyptian ones in all essential features. The earliest depiction of a chariot is on a plaque from Ur, in the museum of the University of Pennsylvania, Philadelphia.

CHARITABLE TRUSTS AND FOUNDATIONS. The foundation is an effective instrument for giving large sums of money. In such newer forms as the community trust and the family foundation, most of its advantages are also available for more modest contributions, or for annual gifts which are expected to grow into a large final amount.

A foundation may be defined as a nongovernmental, nonprofit organization having a principal fund of its own and established to maintain or aid social, educational, charitable, or other activities serving the common welfare. Its predecessors, which were usually endowments for limited purposes, existed from earliest history, at some periods in considerable numbers. The special ingredient which distinguishes the foundation in the American understanding of the name is wide freedom of action. With a very few exceptions, such organizations have arisen only in the United States, and nearly all of them since 1900.

Some legitimate foundations call themselves endowments, trusts, funds, institutions, or boards. On the other hand, because the word "foundation" has acquired an aura of substance and respectability, many organizations use this title with little or no justification. These include agencies which solicit contributions instead of disbursing from an established fund, and some which are trade associations, pressure groups, or outright rackets.

Foundations are a special form of charity, and as such fall under the classic legal definition of Justice Horace Gray (q.v.) in a Massachusetts case of 1867, as a gift to be administered "consistently with existing laws, for the benefit of an indefinite number of persons, either by . . . education or religion, or by relieving their bodies from disease . . . or by assisting them to estab-

lish themselves in life; or by creating or maintaining public buildings or works; or by otherwise lessening the burdens of government."

A variety of legal procedures are available. Some of the earliest foundations were set up by special acts of Congress; among these were the Carnegie Institution of Washington, the Carnegie Foundation for the Advancement of Teaching, and the General Education Board. A few foundations, among them most community trusts, are not incorporated, but operate as charitable trusts under a will, resolution, or instrument of trust. If funds contributed to such a trust are to be tax deductible, they must be committed irrevocably to charitable purposes. Such trusts can be set up within a community trust or in a local bank, thereby freeing the donor from details of investment, accounting, and reporting to the government. These are substantial advantages when the program is not broad enough to warrant the wider freedoms available under the incorporated foundation.

By far the commonest form of organization, however, is incorporation under the laws of a particular state. The laws of incorporation for charitable organizations differ somewhat in the various jurisdictions. The incorporators are usually the original members of the board of trustees (or a part of that board, to be filled out later), and often include the founder. The statement of purpose may be quite specific, or as broad as "the welfare of mankind." In view of many unfortunate experiences with highly restricted perpetuities, the modern tendency has been toward broad statements of purpose, or at least toward the granting of substantial powers to the trustees for effecting changes. In many cases perpetuity is made discretionary, and in some a policy compelling liquidation within a set term of years has been adopted. Many corporate charters, usually to avoid possible question as to their tax-exempt status, follow closely the wording of Section 501(c) (3) of the Internal Revenue Code or similar sections in the laws of their respective states defining a charitable corporation.

Number and Size.—Foundations in the United States probably exceed 5,000 in number, but many of these are small. Russell Sage Foundation's 1950 tabulation of 1,007 larger foundations placed their assets at \$2.6 billion, with an annual expenditure of about \$133 million. Both these figures should be increased because of the creation of additional foundations since that date and the wider information which has become available under compulsory reporting. As of 1953, the assets of the 60 largest foundations totaled \$2.5 billion, with an annual income of \$82 million. It has been estimated that this group holds about half the assets of all foundations, so that total assets of foundations in 1953 might be in the neighborhood of \$4.9 billion.

In the economy of the United States these figures are not large. Americans exhale in tobacco smoke every year more dollars than the accumulated wealth of all the foundations together. But such foundations represent the venture capital of philanthropy, and with their accumulating knowledge of how to give and by applying their funds at strategic places, particularly in research, they have made outstanding contributions in such fields as medicine, public health, education, social welfare, and economic research.

Types of Foundations.—Although few sharp

divisions exist, and not infrequently foundations change in character and program through the years, for purposes of description they may be grouped in the following six main classes.

General Research Foundations.—These foundations have broad charters. They support the research projects in health, welfare, and education which characterize foundation work in the public mind. They include nearly all the larger foundations, and have among them such famous names as the Ford Foundation, Rockefeller Foundation, Carnegie Corporation of New York, and the Commonwealth Fund. Together, they probably account for more than half of all foundation funds.

Special Purpose Foundations.—The trend is away from foundations which are limited, usually by the terms of their charters, to special purposes. Examples, chiefly among older foundations, are the Carnegie Hero Fund Commission and the La Verne Noyes Scholarship Fund. Most such foundations are small, and there is sometimes danger of their special purpose becoming obsolete.

Family or Personal Foundations.—Typically, family foundations are set up by a living person or persons rather than by bequest. The same high tax rates in the upper-income brackets which tend to prevent large accumulations of wealth have encouraged, through the provision for a charitable deduction, the formation of family foundations built up by annual contributions. Generally these foundations are initially small, and have no headquarters other than the office of the donor or of a law firm. They serve as a buffer between the giver and the numerous appeals directed to him, and as a channel through which he and his family can give from varying income, at periods financially convenient. They permit greater leisure for the distribution of gifts, after more adequate investigation and in accordance with a continuing plan. Some of them have served as a means for keeping within a family the control of a tightly held corporation by reducing the founder's taxable estate.

Corporation Foundations.—With the great upsurge of philanthropic giving by corporations, many business companies have organized corporation foundations as a convenient channel for handling their giving and for leveling out contributions between good and bad profit years. It is probable that not fewer than 1,500 such corporation foundations existed in 1953. Though few of them have substantial corpus, serving chiefly as a channel for current giving, some have been able to disburse several million dollars a year. They are a development of great potential importance.

Community Trusts.—These are a special class of foundations concerned with problems of social welfare but acting under community control in a sense seldom found in the usual philanthropic endowment. Most such trusts are organized within a single city, a few bear the name of a county, and several are statewide. Their funds may often be used more widely than their names would suggest; some are applied to international purposes.

These trusts admit separate, named funds, designated for specific purposes. In practically all such trusts, capital gifts or bequests are received and administered as to principal through the trust departments of qualified local banks and trust companies. The income is distributed, to-

gether with such portions of the principal as may be authorized in any trust, under the supervision and control of a distribution committee of citizens selected for their representative character and knowledge of charitable affairs. An important provision is the reservation of power to the distribution committee to transfer to other purposes any funds which can no longer be effectively used for the ends originally designated, thereby avoiding the dangers of rigid perpetuities.

About 100 community trusts are in existence. The National Committee on Community Foundations reported the assets of 94 such trusts at the beginning of 1954 at \$112 million, with disbursements for the preceding year of \$5.6 million.

National Science Foundation.—The only foundation supported out of tax funds is the National Science Foundation, established in 1950, which supports basic research, scholarships, and program coordination in the physical and biological sciences.

Fields of Work.—The humanly appealing causes of direct relief—orphans, widows, crippled children, impoverished age—still attract the funds of many small foundations and of a few larger ones. But most experienced administrators reserve their limited funds for exploratory work directed toward prevention or cure rather than treatment or relief. Discovery is the keynote of their programs—discovery in the physical sciences, discovery in the social sciences, discovery in the application of knowledge already won.

In the Russell Sage Foundation study of 1944, 335 foundations, including almost all the larger ones, reported their fields of substantial interest. Nearly half of them indicated education as a field of major interest, and nearly as many social welfare, which included relief projects. Health, including medical research and medical education, ranked third in number of foundations concentrating in the field, but was probably second in terms of funds expended. All other spheres of activity received far less attention. Recreation was a major interest with 51 foundations, many of them community trusts; 37 specified religion as a major interest; and 26 named international relations and the promotion of peace. Race relations claimed attention from 26. Only 19 were substantially concerned with problems of government and public administration, and the same number—less than 6 per cent— with the whole broad field of economics.

Both this classification and a more detailed examination of projects reveal that there was some concentration on noncontroversial fields. By the early 1950's, however, a pronounced trend was observable on the part of many private foundations away from the older programs centering on relief, routine aid to education, and medical research into the explosive issues of learning to live together in the modern world.

In pursuing these aims, at least three well-defined methods of operation are open to foundations. They may confine their program to the making of grants; they may set up temporary research staffs or experimental projects; or they may maintain a permanent staff for research or service. Most foundations follow the pattern of grant making, confining their professional staff to the persons needed to conduct necessary investigations into the merits of the appeals, handle correspondence, appraise accomplishment, and be the eyes of the foundation, seeking out new op-

portunities for service. But operating programs, or programs combining grants and direct operation, are not uncommon.

Taxation Factors.—High taxation levels have had diverse effects on foundations. Because of the incidence of these taxes few or no personal fortunes are being built up to the dimensions that would permit establishment of such large foundations as the Ford, Carnegie, Rockefeller, or Duke endowments. On the other hand, the tax-exempt status of the foundations themselves attracts contributions from both individuals and corporations in the higher tax brackets, who are able to contribute to foundations of their own choosing or creation at small net cost up to their respective charitable deduction limits. This has resulted in a mushrooming of family and corporation foundations, some of which may grow to substantial size through accumulation of annual additions to their endowment.

Foundations also enjoy exempt status with respect to their own investment income. Prior to 1950 business enterprises which they might conduct were also considered exempt from corporation taxes, since the net profits were dedicated to philanthropic use. A great growth in organizations calling themselves foundations but designed primarily to take advantage of such loopholes in corporate, personal, and estate tax legislation occurred during and after World War II. This was stemmed by the Revenue Act of 1950, which imposes taxes on foundations' unrelated business income, regulates leasebacks, and provides for forfeiture of exempt status if the foundation engages in certain "prohibited transactions" which could benefit the donor or his associates, or if it unreasonably accumulates income; the act also requires public reporting of foundation affairs.

Congressional Investigations.—Foundations, since they enjoy substantial tax and other legal advantages and since their ultimate beneficiary is society itself, are clearly connected with the public interest. The United States Congress has inquired into foundation affairs on various occasions, particularly with respect to taxation, but has conducted only three full-scale investigations, in 1915, 1952, and the Reece Committee investigation beginning in 1953. The 1915 Industrial Relations Commission hearings concentrated on the alleged dangers of foundations as agencies of conservatism and bulwarks of the status quo. The 1952 Select Committee to Investigate Tax-Exempt Foundations and Comparable Organizations (Cox Committee) was charged with just the opposite function; it was to determine "which such foundations and organizations are using their resources for un-American and subversive activities or for purposes not in the interest or tradition of the United States." The published *Hearings* of this committee (see *Bibliography*) constitute a comprehensive source book on the status and activities of United States foundations in the mid-20th century.

The final *Report* of the Cox Committee looked on foundations as "a vital and essential factor in our progress," rendering "great and significant services in many fields." They were not held blameless; mistakes had been made, and some of them were less cautious in their grants than the committee felt desirable. The committee agreed with the foundations that there should be no governmental control of program. Its recommendations were two: fuller public accounting

should be required of all foundations; and the Ways and Means Committee was urged to re-examine pertinent tax laws, with a view to making possible increased "gifts to these meritorious institutions." The Reece Committee had not completed its investigations by mid-1954.

In the light of these findings, and barring major catastrophes of war or finance, United States research foundations, now in their second half century, will continue to be an independent, original, and important force for social progress.

F. EMERSON ANDREWS,
In Charge of Publications and Philanthropic Research, Russell Sage Foundation; Consultant on Publications, Twentieth Century Fund.

CHARITON, kār'i-tōn, Greek romance writer: fl. not later than 2d century A.D. He identifies himself as a native of Aphrodisias in Caria (southwestern Asia Minor) and secretary to the orator Athenagoras. The earliest of the Greek novelists whose works have survived, he was the author of *Chaereas and Callirhoe*.

In the novel *Chaereas* is represented as a citizen of Syracuse. In a jealous rage he strikes his wife, Callirhoe, injuring her so cruelly that she is supposed dead and in fact is buried. Grave robbers, finding her still alive, take her to Miletus, where they sell her as a slave to Dionysius; she consents to marry her master for the sake of her child by Chaereas.

Meanwhile, Chaereas, hearing she still lives, and filled with remorse, goes in search of her. He himself is captured and enslaved. By a cruel irony his master competes with Dionysius for the love of Callirhoe. They invite the king of Persia to arbitrate, but he too falls a victim to her charms. The news of Egypt's revolt from Persian rule separates the suitors. Chaereas, escaping, joins the Egyptian fleet and leads it to victory over the Persians. He captures a ship containing all the women of the Persian court, including Callirhoe, then sails back to Syracuse with her, and they live happily ever after.

CHARITON, shār'i-t'n, city, Iowa, seat of Lucas County, situated at an altitude of 1,040 feet, on the Chariton River, and on the Burlington and the Chicago, Rock Island and Pacific

railroads, 42 miles south-southeast of Des Moines. The trading center of an agricultural and coal mining region, it has railroad shops and establishments producing brooms, clothing, dairy products, and chemicals. The city has a public library and owns its waterworks and an airport.

Founded in 1849 and incorporated in 1857, Chariton is governed by a mayor and council. Pop. (1950) 5,320.

CHARITY (Fr. *charité*, Lat. *caritas*, high regard, love), one of the seven Christian virtues. In its fullest sense, it is a disposition of mind to love God for Himself alone and mankind for His sake. The word was used in translating the New Testament as a rendering of the Greek *agapē*, meaning "love," and in later versions of the New Testament the latter has been employed instead of "charity," which has come to be used more often in modern English in the sense of charitableness—that is, goodwill to the poor and generosity to worthy causes. In the New Testament, the word charity is never used purely in the sense of almsgiving.

Consideration for the poor and suffering dates back to very early times. In the Old Testament we find such references as those in Deuteronomy 15:7-15, which makes every seventh year a year of liberality to the poor, in which the blessings of God should be shared with those less fortunate; and in Isaiah 58:6, 7, in which a true fast is described as giving food, shelter, and clothing to the poor. Obedience to God and pity for the unfortunate combined to make charity a practice among the ancient Hebrews, and it was emphasized in the Talmud and later Jewish writings.

In ancient Greece the practice of charity grew out of the emphasis placed on hospitality, and there are frequent references in classical Greek literature to the giving of alms to beggars and wayfarers. There was, however, relatively little conception of the religious or ethical connotations of benevolence. In Rome the wealthy made liberal donations to the poor, and public charity, notably in the form of gifts of grain to the urban proletariat, was widespread.

In Hinduism the giving of alms is considered a religious obligation—part of the endeavor to pursue a righteous life. Late Buddhist writings list proper ways of giving alms; if the recipient is worthy, the merit of the gift is increased.

One of the five basic tenets of Islam is the duty to give alms, and *ṣawq*, the dedication of property for religious, pious, or charitable purposes, forms an important part of Moslem law.

Christianity, by its insistence on the worth of each individual, made charity a universal practice. Following the teachings of Christ, as in the Sermon on the Mount, the early Christians emphasized the practice of benevolence toward their fellow men. Contributions were made for the poor of each congregation; later the relief of poverty and suffering was organized on a diocesan scale, and such institutions as hospitals and refuges were established. In the Middle Ages charity was almost entirely the province of the church. Later lay organizations arose, and governments began to assume responsibility for public welfare. CHARLEMAGNE, shär'lē-mān (Fr. shär-lē-mān'y; known also as CHARLES THE GREAT and CHARLES I), king of the Franks and emperor of the West: d. Aachen (Aix-la-Chapelle), Germany, Jan. 28, 814. The grandson of Charles Martel and the son of Pepin the Short, he was the second Carolingian king of the Franks and the first Christian emperor of the West. He sprang from a line of Austrasian counts, the Arnulfings or Carolings, who, as mayors of the palace, had first dominated and then replaced the weak Merovingian rulers of the Frankish kingdom. The place of his birth is unknown, but it may have been Aachen, destined to become his capital. The date, too, is uncertain, though the year 742 fits such evidence as we have. According to an important source, he was born out of wedlock, his parents, Pepin and Bertha (the Big-Footed Bertha of later legend), not marrying until he was six or seven years old. He first appears in history at the important ceremony held in St. Denis in 754, at which Pope Stephen III anointed Pepin king of the Franks and associated with him in that act of consecration both Charlemagne and his younger brother Carloman. It was to this crown, given by the Frankish nobles to their elected king and blessed by the head of the Western Church, that Charlemagne and Carloman succeeded as joint heirs when Pepin died on Sept. 24, 768. This division of the kingdom was in accordance with Frankish custom, but it threatened to weaken a state to which Pepin had brought unity and strength. The threat was to vanish with the death of Carloman on Dec. 4, 771.

The weakness became apparent, however, during the three years when each brother reigned in his separate kingdom. They were crowned on the same day, Oct. 9, 768, Charlemagne at Noyon, Carloman at Soissons. Hardly were the ceremonies over when revolt broke out in Aquitania. Charlemagne's first battles had been fought in that restless province, when he accompanied his father on the campaign against Waifer (Gaifier) which ended successfully with the latter's death on June 2, 768. This time, knowing the seriousness of the situation, Charlemagne sought his brother's help. It was refused. Charlemagne marched with his own forces and crushed the revolt unaided.

On his return to Aachen, he found that he was being enmeshed by Carloman and the queen mother in a Lombard alliance. Desiderius, king of the Lombards, was seeking to extend his sovereignty over all Italy, a policy viewed with alarm by the pope. In the process of wooing Frankish goodwill, Desiderius had persuaded Bertha to bring about the marriage of Charlemagne and Carloman with his two daughters and of her own daughter, Gisela, with his son. The sudden death of Carloman, and the union of the two kingdoms under his own scepter, gave Charlemagne the power and the freedom to act decisively. He saw, as Pepin had seen, that to be truly strong the Frankish monarchy needed the support of the pope. He broke with his mother's policy, sent his humiliated wife home to her father, reassured the pope, and led an

army into Italy. In April 774, while Desiderius was blockaded in Pavia, Charlemagne celebrated Easter with Pope Adrian I in Rome. Pavia fell in June. Desiderius was sent off to a monastery, the papal states which he had usurped were restored to the Holy See, and Charlemagne took the title "King of the Franks and Lombards, Patrician of the Romans." King indeed he was, of a strengthened and respected Francia and of a submissive Lombardy. As patrician of the Romans, he became the guarantor of the temporal possessions of the pope in Rome and central Italy. Henceforth in all his enterprises of war or peace, he was to be guided by the twofold purpose of serving at once the interests of his expanding Frankish state and those of the Roman Church.

For long years these policies had to be pursued in war. Already in 772 he had undertaken a successful expedition against the Saxons. These pagan, barbarian, and indomitably hostile tribes occupied the vast region lying between the Rhine and the Elbe. From 774 to 804 a succession of bitter campaigns was fought. The Saxons found a national leader in Wittekind, who severely defeated the Franks in 782 at Sintel; Charlemagne retaliated with a frightful massacre at Verden. In 785, Wittekind submitted and was baptized. The conquest of Saxony seemed to be complete, but war broke out again in 793. Relentlessly, cruelly, using at the last mass deportations, Charlemagne finally crushed Saxon resistance. Christianization went hand in hand with conquest, and a new political and ecclesiastical organization laid the foundations of a future Germany.

In the expanding dominions of Charlemagne, Bavaria, under Duke Tassilo, took on a new strategic importance. Tassilo had sided with Desiderius in the Lombard war. Charlemagne was in no mood to tolerate even his independence. Tassilo made a show of intractability. But he was soon toppled from his throne and, in 794, his domains were incorporated in the Frankish state.

The thrust into Bavaria brought Charlemagne into contact with the Avars, a Turko-Mongol people settled in the region of the middle Danube. Two campaigns were fought against them, the first in 791, the second in 795. In the latter, Duke Eric of Friuli led an Italian army to the heart of the Avar country, captured the fortified encampment of the Ring and took immense booty.

The dates of these many campaigns show that Charlemagne had to fight simultaneously on many fronts. In 778, at the solicitation of Suleiman ibn-al-Arabi, governor of Saragossa, he crossed the Pyrenees, took Pamplona, and reached the walls of Saragossa. But there Suleiman failed him. In the retreat which followed, the Franks were caught in the western passes of the Pyrenees by the Basques, who fell upon them, pillaged their baggage train, and made away with the spoils into their mountain fastnesses. The episode provided the historical nucleus for the old French epic poem, the *Chanson de Roland*. The defeat taught Charlemagne a lesson. His policy henceforth with regard to Spain was defensive. He organized his military defenses in the south under the leadership of Guillaume d'Orange. After an early defeat near Carcassonne in 793, Guillaume carried the war across the Pyrenees. From 798 until 803, cooperating with Louis, the young son whom Charlemagne had made king of

Aquitania, Guillaume methodically went about his business of establishing the Spanish March as a buffer against the might of Moslem Spain, an objective achieved by the capture of Barcelona in 803. Proceeding from the Asturias, a similar effort had established the Western March in Navarre.

But already, in the year 800, a decisive event had taken place. On Christmas Day of that year in St. Peter's Church in Rome, Leo III placed on Charlemagne's head the imperial crown, while the crowd cried in acclamation, "Charlemagne Augustus, Emperor of the Romans!" The act marked at once a culmination and a starting point. Charlemagne had forged the empire of western Europe in the fire of war. As his domains spread, he saw to it that Christian civilization spread with them. In accepting the imperial crown at the hands of the pope, the new emperor accepted the church's consecration of his power. In him, at that moment, the Holy Roman Empire was founded, renovating in western Europe the glory of the old Roman Empire, but incorporating the new principle by which the temporal interests of the emperor and his subjects were identified with the spiritual interests of the pope and his Christian flock. The period of war and conquest was over for Charlemagne. He had now to prove his statesmanship in other ways: to come to an understanding with Byzantium, to clarify his relations with the pope, and to administer his empire.

In his Byzantine policy, Charlemagne moved with circumspection, succeeding finally in 812 in winning the recognition of the Eastern emperor. He faced, in his relations with the pope, the great problem of the Middle Ages, the problem of church and state. He solved it in the main simply by being what he was, a strong and pious emperor, fighting the church's battles in his own. His victories were not won only on the battlefield. In the administration of his vast realm he established a strong, centralized government, organized local affairs in the hands of counts, and exercised continuous supervision by means of his intendants. Justice was reorganized, commerce regularized and stimulated. Under the last Merovingians the intellectual and artistic life of Francia had been almost extinguished. Charlemagne's first concern in this regard was to re-educate the clergy. To make good the lack of scholars, he brought to France learned and renowned teachers from abroad, Alcuin from England, Paulus Diaconus from Italy. With their aid he founded cathedral and monastic schools, and established the seven liberal arts as the general program of studies. The result, not fully apparent until after his death, was a veritable renaissance in letters and in art. His drive toward thoroughgoing reorganization and reform was no less effective in ecclesiastical matters. He set up a whole system of metropolitan archbishoprics having precedence over other sees; he bettered the lot of the humble priest by enforcing the payment of tithes. He brought unity into a disorderly ritual by regularizing the liturgical books. He did not hesitate to take a stand on matters of dogma, inserting the *filioque* in the Nicene Creed despite the opposition of Popes Adrian and Leo, and, at the Council of Frankfurt in 794, denouncing the adoptionism of Bishop Felix of Urgel.

He was mindful, too, of the future. In 806, with what inner misgivings we shall never know,

he divided the empire among his three sons, Charles, Pepin, and Louis. But Pepin died in 810 and Charles in 811, and Louis was acclaimed sole heir in 813. In the following year, on January 28, Charlemagne died.

He lived on, however, in the memory of the Middle Ages as the very embodiment of the ideal Christian emperor. So he appears in the *Chanson de Roland* and in the so-called *Chronicle of Turpin*. It was even written that he had been to the Holy Land, and indeed, his cordial relations with Harun al-Rashid, who allowed him to give pilgrims to Jerusalem every advantage, afforded some historical basis for the tale. The Turpin portrait was carried over into medieval English romance. His name survives in the epic and ballad literature of Spain and in the chivalric romances of Italy. In Germany, where, on Dec. 29, 1165, he was canonized by the antipope Paschal III, he was claimed as the ancestor of the German line of emperors, honored as patron, sung as hero throughout the length and breadth of the land. It was believed in France, about 1300, that he had founded the University of Paris, which adopted him later as its patron saint. The legend of Charlemagne, in which spontaneous admiration mingles with the calculated fictions of interested propaganda, bears witness at once to the glory of his reign and the decadence which followed it. He realized in his personality and achievement a universality of authority which had survived in western Europe as a memory since the collapse of imperial Rome, and which was lost after his death in a welter of warring feudal and national entities.

RONALD N. WALPOLE.

CHARLEROI or **CHARLEROY**, shâr-lê-rwä', town, Belgium, situated in Hainaut Province, on the Sambre River, 34 miles south of Brussels, with which it is connected by rail and canal. In the center of an area with rich coal deposits, it is almost exclusively a manufacturing town, containing some of the principal iron and steel plants of Belgium. Greater Charleroi formerly comprised 40 communes which grew up around the pit heads and foundries, and it is in these that the heavy industries are located. Third in importance, following coal mining and steel, is the glass industry, which has declined since the 18th and 19th centuries. Other establishments produce machinery, electrical equipment, cement, beer, and flour.

The town, which is built on rising ground on both banks of the river, is the seat of the Université du Travail. It has a 17th century church and chapel, an archaeological museum, and a fine archaeological library.

History.—Little is known of the early history

of Charleroi, originally called Charnoy, beyond brief references in a 9th century manuscript and a 13th century document. Recognized early as a site of strategic importance, the high ground now occupied by the town was fortified in 1006 by Spain, then in possession of what is now Belgium, and the name was changed to Charleroi in honor of the reigning Spanish king, Charles II. The development of Charleroi as a modern town dates from this time. In 1667, when Louis XIV sent 60,000 troops against the Low Countries, the Spaniards destroyed their fortress with mines, but it was immediately rebuilt by the marquis de Vauban.

During World War I, on Aug. 22, 1914, the German Second Army attacked Charleroi, which was the headquarters of the French Fifth Army. The battle raged through the streets until the French were forced to withdraw on the following day [see also WAR, EUROPEAN—*Military Operations on the Western Front* (From the Sambre to the Marne)]. During World War II the town was not defended by the French and Belgian troops, and after scattered bombing it was occupied on May 15, 1940. The enemy occupation lasted four years, during which the outlying industrial communes were bombed by United States and British air forces. In September 1944, the German forces withdrew from Charleroi before the advancing American troops. Pop. (est. 1951) 25,624.

CHARLEROI, shär'lē-roī, borough, Pennsylvania, situated in Washington County, at an altitude of 765 feet, on the navigable Monongahela River and the Pennsylvania Railroad, 22 miles south of Pittsburgh. In a coal mining and agricultural region, it has establishments producing steel, glass, paper boxes, and beverages.

Laid out in 1890 and named for the Belgian glass and iron industrial center, Charleroi was incorporated in 1892. It is governed by a burgess and council. Pop. (1950) 9,872.

CHARLES I (in full CHARLES FRANCIS JOSEPH; Ger. KARL FRANZ JOSEF), emperor of Austria and, as CHARLES IV, king of Hungary: b. Persenbeug, Austria, Aug. 17, 1887; d. Funchal, Madeira, April 1, 1922. Grandson of Charles Louis (q.v.), archduke of Austria (brother of Emperor Francis Joseph), and son of Archduke Otto and of Princess Maria Josepha of Saxony, he married Zita, princess of Bourbon and Parma, in 1911. He became heir apparent to the Austrian and Hungarian thrones on the assassination of his uncle, Archduke Francis Ferdinand, at Sarajevo on June 28, 1914. On the death of Francis Joseph, on Nov. 21, 1916, he succeeded as emperor and king, but abdicated on Nov. 12, 1918, and retired to Switzerland. In March and October 1921, he entered Hungary in unsuccessful attempts to regain the throne. After the second attempt he was exiled by the Allies to Madeira.

CHARLES I, king of Great Britain and Ireland: b. Dunfermline, Scotland, Nov. 19, 1600; d. London, England, Jan. 30, 1649. The second son of James I and Anne of Denmark, he was created duke of York in 1605; in 1612, on the death of his older brother, Prince Henry, he became heir apparent to the throne. He was created prince of Wales in 1616. Little is recorded of him before his romantic journey to

Spain in 1623, in the company of George Villiers, 1st duke of Buckingham, to pay court to the Infanta Maria. Because of religious and political differences the match was prevented, and soon thereafter Charles was betrothed to Henrietta Maria, daughter of Henry IV of France, whom he married after he succeeded his father on the throne in 1625.

The first Parliament which he summoned was dissolved after it had failed to grant him sufficient supplies. By loans and other expedients an expedition was then fitted out against Spain (1626), but it was shattered by a storm. Meanwhile, a new Parliament had been summoned. The distrust prevailing between this assembly and the king laid the foundations for the misfortunes of his reign. Suddenly and angrily he dissolved Parliament after a short session, while the House of Commons was preparing a remonstrance against the levying of tonnage and poundage without the consent of Parliament. He then began to raise funds by means of loans, benevolences, and other procedures, which, though partially sanctioned by precedent, were entirely opposed to the rising spirit of civil liberty and to the constitutional principal which gave control of the public purse to the House of Commons. The king's difficulties were increased by a war with France, in which Buckingham added to the odium against him by an ill-fated expedition to assist the Huguenots of La Rochelle (1627).

In 1628, Charles was obliged to call a third Parliament, which proved to be as much opposed to arbitrary measures as its predecessors, and, after voting supplies, prepared the Petition of Right (q.v.), to which the king was forced to give his assent.

The assassination of Buckingham in August 1628 removed one source of discord, but the Parliament which met in January 1629 showed so determined a spirit against the king's claim of levying tonnage and poundage by his own authority that it was suddenly dissolved. Charles then determined to reign without one, and for this purpose he raised Sir Thomas Wentworth (later 1st earl of Strafford) to the chief place in his councils. In 1629 peace was concluded with France, and in the following year with Spain. In ecclesiastical affairs the king was guided by William Laud, then bishop of London, a strong opponent of Calvinism and Presbyterianism. In Laud's hands the arbitrary Court of High Commission and the Star Chamber were a source of great oppression. To his other expedients for raising funds, Charles added the levying of ship money, at first (1634) from seaports, but in the following year from inland counties as well. John Hampden then began his resistance to the payment of ship money, which he held could not be levied without the authority of Parliament. His cause was argued in 1638, and although he lost the decision, the discussion of the question aroused widespread comment.

It was in Scotland, however, that Charles' opponents first resorted to war. From the beginning of his reign the king had endeavored to introduce into that country a liturgy patterned after that of the Church of England—an innovation which resulted, in 1638, in the formation of the National Covenant, by which great numbers of Scots pledged themselves to stand by each other and resist the imposition of the episcopacy. The Covenanters, as they were called, raised an army, which the king opposed by an ill-discipline

English force, and in 1639 he was forced to agree to the Treaty of Berwick. His finances exhausted after an intermission of 11 years, he again assembled Parliament, in 1640. That body, as usual, began to state grievances before granting supplies, and the king hastily dissolved it and prosecuted several members who had distinguished themselves by their opposition. Raising money by whatever means he could devise, he again sent an army north, but it was defeated by the Scots, and it became obvious that affairs could no longer be managed without Parliament.

That body, which met in November 1640, proved to be the famous Long Parliament (q.v.). It began by impeaching Strafford and Laud (both were subsequently tried under bills of attainder and beheaded, the former in 1641 and the latter in 1645), and then, on Nov. 22, 1641, framed the Grand Remonstrance (q.v.), recapitulating all the king's abuses. In the House of Lords, Charles had his attorney general enter an accusation against five members of the House of Commons who had led in passing the remonstrance, and sent a sergeant at arms to the Commons to demand them. Receiving an evasive answer, he himself proceeded on the following day (Jan. 4, 1642) to the Commons with an armed retinue to seize their persons. Aware of Charles' intention, the five had previously withdrawn, but the king's appearance with a guard caused the Commons to break up in great disorder and indignation. The accused members retired to the City of London, where a committee of the Commons was appointed to sit. The City's militia was mustered under an officer appointed by Parliament, which also demanded control of the army. The queen fled to the Netherlands to procure ammunition, and Charles, with the prince of Wales, went north and for a time resided in York. The king was received with great demonstrations of loyalty from the gentry, and many persons who had hitherto been conscientious opponents of his arbitrary measures now joined his party. The Puritans and the inhabitants of the great trading towns sided with Parliament.

The royal standard was raised at Nottingham on Aug. 22, 1642. The first action of consequence in the ensuing civil war was the Battle of Edge Hill, on Oct. 23, 1642, but nothing decisive occurred until the Battle of Marston Moor (July 2, 1644), in which the Parliamentarians were victorious chiefly because of the skill and valor of Oliver Cromwell. The successes of James Graham, 1st marquess of Montrose, in the Scottish Highlands in 1644-1645 created diversions in favor of the Royalists, but the loss of the Battle of Naseby (June 14, 1645) completed the ruin of the king's cause. Charles at first retired to Oxford, and then, on May 5, 1646, decided to place himself in the hands of the Scottish Army, then at Newark. He was received with respect, though placed under guard. After a series of abortive negotiations an agreement was made with Parliament to surrender him to its commissioners, and, on Jan. 30, 1647, he was accordingly handed over to them. Taken at first to Holmby House in Northamptonshire, he was subsequently moved to the headquarters of the army at Reading, and soon thereafter to Hampton Court. Fearing for his personal safety, the king then escaped with a few attendants and fled to the south coast. Crossing to the Isle of Wight, he put himself in the hands of its governor, Col. Robert Hammond, who lodged him in Carisbrooke Castle.

Meanwhile, the Scots, regretting the manner in which they had delivered Charles to the commissioners and dissatisfied with the measures taken by Parliament, sent a considerable army to the king's relief, under the command of the 2d duke of Hamilton. This force, though strengthened by a large body of English Royalists, was routed by Cromwell at Preston, as were the insurgents in Kent and Essex by Thomas Fairfax (later 2d Baron Fairfax). Fresh negotiations were opened with the king at the Isle of Wight, and he agreed to nearly everything demanded of him except the abolition of the episcopacy. Parliament then accepted the king's concessions as sufficient grounds for a treaty. On its return, however, the triumphant army cleared the Commons by what is known as Pride's Purge (see PRIDE, THOMAS) of all the members opposed to its views (Dec. 6, 1648), and thereby secured a reversal of the decision. The king was taken from the Isle of Wight to Hurst Castle, while preparations were made to try him on a charge of high treason. As the House of Lords refused to concur in a vote for this purpose, the Commons declared its consent unnecessary. Charles was taken to London and brought before a special court of 67 judges on Jan. 20, 1649. His behavior was calm and dignified throughout the trial. He objected three times to the court's authority, supporting his position with cogent arguments. At length, however, he was sentenced to death and, on January 30, was beheaded before Whitehall.

CHARLES II, king of Great Britain and Ireland: b. London, England, May 29, 1630; d. there, Feb. 6, 1685. The second son of Charles I and Queen Henrietta Maria, he took his seat in the House of Lords in 1640. Two years later he was present at the Battle of Edge Hill, and he resided with his father at Oxford and Bristol. After the Royalist defeat at Naseby (1645), he went to Cornwall and then, in 1646, to the Scilly Isles and Jersey. At his mother's entreaty, he proceeded to Paris, where he remained until 1648. In that year he took part in an expedition which sailed from the Netherlands to the Thames River, where it took some prizes. He then settled in The Hague and made several vain attempts to save his father's life. After the latter was executed, on Jan. 30, 1649, Charles assumed the royal title. Eventually he accepted an invitation from the Scots, who had proclaimed him their king on Feb. 5, 1649, and arrived in Cromarty Firth on June 16, 1650. He signed a declaration in which he made a number of concessions to the Scots. Meanwhile, the army of Oliver Cromwell had entered Scotland; on Sept. 3, 1650, it defeated the Scots at Dunbar. On Jan. 1, 1651, Charles was crowned at Scone; accepting the Covenant, he promised to support Presbyterianism throughout Great Britain. The approach of Cromwell made his stay in Scotland unsafe, and, hoping to find support, he entered England, where he was welcomed at Carlisle. He was immediately pursued by Cromwell, who, with a superior army, won the Battle of Worcester (Sept. 3, 1651). Charles, after a succession of narrow escapes (including the necessity of taking shelter in the celebrated Royal Oak at Boscobel), reached Shoreham, Sussex, and from there fled to France (Oct. 16, 1651). For nine years he remained an exile on the Con-

tinent. (For an account of the events leading to the Restoration, see *GREAT BRITAIN—History*.)

Charles was proclaimed king in London on May 8, 1660, and landed at Dover on May 26. Three days later, he entered his capital, where he was joyfully acclaimed. His first acts as king were prudent and conciliatory. Edward Hyde, 1st earl of Clarendon, was made lord chancellor, and an act of indemnity, from which only those immediately concerned in the death of Charles I were excluded, was passed. A settled revenue was accepted in lieu of wardship and purveyance, and the army was reduced. With regard to religion there was less indulgence; not only were the prelacy and the parliamentary rights of bishops restored, but an Act of Uniformity (1662) was passed, under which nearly all the Presbyterian clergy were forced to resign their livings. In 1662, Charles married Catherine of Braganza, to whom he was flagrantly unfaithful. The extravagance of his way of life soon involved him in financial difficulties, which the unpopular sale of Dunkerque to the French (1662) was undertaken to relieve.

In 1665 a war broke out with the Netherlands. Great Britain at first enjoyed some naval victories, but when France and Denmark entered the conflict as allies of the Dutch, the British were overmatched. A Dutch fleet entered the Thames and, proceeding up the Medway, burned and destroyed ships as far as Chatham (June 13, 1667), and Charles had to conclude peace at Breda. Meanwhile, there were the domestic calamities of a dreadful plague in 1665, and of the Great Fire of London in the following year. In 1667, Clarendon, who had become very unpopular, was dismissed and went into exile. Charles then put himself at the disposition of five unprincipled ministers, known collectively as the Cabal (q.v.). An alliance with the Netherlands and Sweden, for the purpose of checking the ambition of Louis XIV, was concluded in 1668. This policy was reversed, when, on May 20, 1670, there was signed the secret Treaty of Dover, under which Charles agreed to join the French in a war against the Netherlands and to declare himself a Roman Catholic. In return, the king received subsidies from France and thus became a pensioner of Louis XIV. As he did not wish to apply to Parliament for money to carry on the projected war, he had the Exchequer shut up in January 1672. The naval operations of that year against the Dutch were not successful, and when a new Parliament was called (1673), the Cabal was dissolved, and in the following year Great Britain made a separate peace with the Netherlands. Meanwhile, Charles was obliged, under parliamentary pressure, to cancel the Declaration of Indulgence (q.v.), and Parliament passed the Test Act (1673), which resulted in the removal of Roman Catholics from office.

Negotiations for the marriage of the king's niece, Princess Mary, with William of Orange began in 1674. Charles, at first opposed, eventually gave way to popular feeling, and in 1677 the marriage took place. Despite this rapprochement with the Netherlands (the king also was instrumental in arranging the Peace of Nijmegen between France and the Netherlands in 1678), Charles made two further secret treaties with Louis (1676, 1678). The year 1678 was notable for the pretended discovery by Titus Oates (q.v.) of the Popish Plot for the assassination of the king and the introduction of the Roman Catholic

faith. Despite the improbable nature of the pretended plot, the tale of Oates and William Bedloe, supported by general suspicion of the secret influence of a Roman Catholic faction, was widely believed, and many persons were accused and imprisoned. Among those who lost their lives was William Howard, 1st Viscount Stafford. The duke of York (the future James II), a Roman Catholic, was forced to retire to Brussels. In 1679, Parliament passed the Habeas Corpus Act. The king now sought to establish a balance of parties, and from the elections of this period dates the use of the terms Whig and Tory. In 1680 a bill excluding James from succession to the throne was passed by the House of Commons, but it was rejected by the House of Lords. Early in 1681, Charles dissolved Parliament, and a new one was called at Oxford, but it proved so determined to oppose him that he soon dissolved it and, like his father, determined to govern without one.

Shortly after the dissolution of Parliament, the king issued a declaration in which he listed what he considered to be its faults and protested his devotion to Protestantism. This was followed by loyal addresses from all parts of the kingdom, and the king regained some measure of popularity. His brother, who had been recalled from the Continent and made high commissioner of Scotland in 1679, oppressed the Covenanters, and in England the penal laws were strictly enforced against the Nonconformists. An important step in the growth of arbitrary power was the institution of suits (*quo warrantos*) against most of the corporations in the kingdom, by which they were intimidated into resigning their charters, receiving them back in a much more restricted form. Meanwhile, opposition to the king on the part of the extreme Whigs had been growing, and it culminated in 1683 in the celebrated Rye House Plot (q.v.). Besides the actual conspirators, who may have intended the assassination of the king and his brother, many opposition leaders were arrested. Among those executed for their supposed implication in the plot were William Russell and Algernon Sidney. James Scott, duke of Monmouth, the king's illegitimate son (who had been favored as heir to the throne by some of those who had endeavored to exclude James), fled to the Netherlands. The king's health had been poor for several years, and in 1685, shortly after he had suffered a stroke, he died. On his deathbed, he professed himself a Roman Catholic and received the last sacraments of the church.

Consult Clark, G. N., *The Later Stuarts* (London 1934); Bryant, Arthur, *King Charles II*, complete ed. (London 1949).

CHARLES (in full **CHARLES PHILIP ARTHUR GEORGE**), PRINCE (DUKE OF CORNWALL), son of Queen Elizabeth II of Great Britain: b. London, England, Nov. 14, 1948. On the accession of his mother to the British crown on Feb. 6, 1952, he became heir apparent.

CHARLES I, king of France. See **CHARLES II**, Holy Roman emperor.

CHARLES II, king of France. See **CHARLES III**, Holy Roman emperor.

CHARLES III (called **CHARLES THE SIMPLE**), king of France: b. Sept. 17, 879; d. Péronne, France, Oct. 7, 929. He was the posthumous son

of King Louis II (the Stammerer). On his father's death France had been divided between Charles' two brothers, Louis III and Carloman, and when they died in their turn, his extreme youth prevented the recognition of his claims to the throne. Accordingly, his cousin, Charles the Fat, was proclaimed king as Charles II in 884. On the deposition of the latter three years later, Eudes, count of Paris, succeeded in obtaining the crown, but his death in 898 left Charles the Simple undisputed king of the whole country. His reign is noted chiefly for the piratical incursions of the Norsemen or Normans, who ravaged the coasts of France and sailed up the principal rivers. In 911, to put an end to their depredations, Charles ceded to their chief, Rollo, a large part of what came to be called Normandy, to be held as a fief of the French crown. In the same year the king acquired Lorraine. The last years of his reign were disturbed by the turbulence of some of his great vassals, who broke into open rebellion, declared the throne forfeited, and, in 922, proclaimed as king Robert I, count of Paris, brother of Eudes. In the following year, through the treachery of Herbert de Vermandois, Charles was inveigled into the town of Péronne and imprisoned in its fortress, where he remained until his death six years later.

CHARLES IV (called **CHARLES THE FAIR**; Fr. **CHARLES LE BEL**), king of France and, as **CHARLES I**, king of Navarre: b. 1294; d. Vincennes, France, Feb. 1, 1328. The third son of King Philip IV and Jeanne de Navarre, he ascended the throne in 1322 by virtue of the Salic law (q.v.), to the exclusion of the daughter of Philip V. His sister, Isabella of France, married Edward II of England. With her paramour, Roger de Mortimer, she was aided by Charles in fitting out the expedition which resulted in the dethronement of her husband in 1327. In the following year, Charles died without male issue, the last sovereign of the direct line descended from Hugh Capet, and the succession passed to the house of Valois.

CHARLES V (called **CHARLES THE WISE**; Fr. **CHARLES LE SAGE**), king of France: b. Vincennes, France, Jan. 21, 1337; d. Château de Beauté, Fontenay-sous-Bois, Sept. 16, 1380. The son of King John II, he was created duke of Normandy in 1355. In the following year, after the Battle of Poitiers, his father was imprisoned in England, and Charles became regent of France. The kingdom had been misgoverned for years, and the young regent was faced with demands for reform put forth by the States-General, headed by Étienne Marcel, provost of the merchants of Paris. This assembly was supported in its claims by Charles II, king of Navarre, who, as a grandson of King Louis X, claimed the French crown. By temporizing, the regent was able to detach some of the supporters of the States-General and, after he had brought about indirectly the murder of Marcel (1358), succeeded in crushing their party. In the following year a peasants' revolt known as the *Jacquerie* was put down. Meanwhile, King John remained a captive in England until 1360, when he was liberated by the Treaty of Brétigny. Four years later he died, and Charles ascended the throne. The new king re-established the finances of the crown. He was able to hold at bay Charles II of Navarre and, through the great efforts of Bertrand Du Guesclin,

to drive the English forces from south and west France. A patron of literature and art, he assembled the nucleus of the royal library at the Louvre.

CHARLES VI (called **CHARLES THE WELL-BELOVED**; Fr. **CHARLES LE BIEN-AIMÉ**), king of France: b. Paris, France, Dec. 3, 1368; d. there, Oct. 21, 1422. The son of Charles V, he was not 12 years old when his father died, and the rivalry of his uncles, the dukes of Anjou, Berry, Burgundy, and Bourbon, made the period of his minority (1380-1388) one of great turbulence. In 1385 he married Isabeau of Bavaria, and three years later declared himself independent of guardians. His mild and amiable character had won him some popularity with his subjects when, in 1392, he became insane; for the rest of his life he had few lucid intervals. Perhaps at no period in her history was France in a worse condition than during Charles' reign. The rival factions of the Burgundians and the Armagnacs (as the supporters of the houses of Burgundy and Orléans were called, respectively) kept the country in an almost continual state of civil war, and brigandage and violence prevailed. The situation afforded a favorable opportunity for an invasion, and in 1415, King Henry V of England crossed over to Normandy with a substantial force, took Harfleur by storm, and routed the French forces in the Battle of Agincourt. Advancing into the country, he took the capital and compelled the king to sign the Peace of Troyes (1420), by which the latter's daughter, Catherine of Valois, was given in marriage to Henry, and Charles was forced to disinherit his own son (the future Charles VII) and to acknowledge Henry as his successor.

CHARLES VII, king of France: b. Paris, France, Feb. 22, 1403; d. Mehun-sur-Yèvre, July 22, 1461. The fifth son of King Charles VI, he became dauphin in 1417, following the successive deaths of his elder brothers. In 1420, under the terms of the Peace of Troyes, he was disinherited in favor of Henry V of England, and two years later, after the deaths of Henry and Charles VI, Henry's infant son (Henry VI of England) was proclaimed king of France at Paris. With the support of the Armagnacs (adherents of the house of Orléans), Charles was crowned king at Poitiers in 1422. Weak and vacillating, he remained at Bourges, while his supporters fought the English, who were commanded by John of Lancaster, duke of Bedford. So successfully did the duke conduct operations that Charles was almost reduced to abandon the struggle as hopeless when, in 1429, his fortunes were retrieved by the arrival at Bourges of Joan of Arc (q.v.). By the enthusiasm she inspired the tide was turned: the siege of Orléans was raised, and Charles was crowned in Reims Cathedral. The fresh spirit infused in the French was heightened by the mismanagement of the English, whose military operations were much less skillfully conducted after the death, in 1435, of the duke of Bedford. In 1444, through the intervention of William de la Pole, 4th earl of Suffolk, a marriage was arranged between Henry VI and Margaret of Anjou, niece of Charles' queen, Marie (the ceremony took place the following year). Shortly thereafter an Anglo-French truce was arranged at Tours. Peace lasted until 1449, when the English took Fougères. With the resumption of hostilities, Charles' troops were generally successful, and by 1453 they had expelled the English from all their possessions in France

except Calais. The last years of Charles' reign were embittered by domestic difficulties, in which the king's son and successor, the future Louis XI, took a prominent part against his father.

CHARLES VIII, king of France: b. Amboise, France, June 30, 1470; d. there, April 7, 1498. The son of King Louis XI, he succeeded his father in 1483, his sister, Anne de Beaujeu, acting as regent until 1491. In that year he married Anne de Bretagne. Although he thereby acquired Brittany for the French crown, to do so he broke his engagement with Margaret of Austria, daughter of Emperor Maximilian I, and also deprived Maximilian of his bride, a marriage by proxy having previously been arranged between the latter and Anne. The leading event of Charles' reign was his expedition to Italy and conquest of the Kingdom of Naples, a project in which he engaged at the instigation of Lodovico Sforza, the usurping duke of Milan. Charles' pretension to Naples was asserted by virtue of rights transmitted by the house of Anjou to the French royal family. The expedition began in September 1494, when, with an army of 30,000 men, the king suddenly crossed the Alps and entered Italy. After expelling the Medici from Florence, he advanced rapidly southward and, meeting almost no opposition, entered the city of Naples on Feb. 22, 1495. He did not retain his conquest long, however, for a coalition was formed against him, and after he returned to France, in November of that year, a Spanish force under Gonzalo Hernández de Córdoba effected the re-annexation of Naples to Spain. Although Charles' expedition had little immediate effect on Italy, it was significant as the first of a series of French invasions of the peninsula. Moreover, it marked the beginning of important Italian cultural influences on France. Charles, who died at an early age as the result of an accident, left no children, and was succeeded by a distant cousin, the duke of Orléans, under the title of Louis XII.

CHARLES IX, king of France: b. St-Germain-en-Laye, France, June 27, 1550; d. Vincennes, May 30, 1574. The second son of King Henry II and Catherine de' Medici, he ascended the throne in 1560, following the death of his brother, Francis II. His mother forced the retirement of François de Lorraine, 2d duc de Guise, and assumed the regency. The religious conflict, which had been growing in intensity for a number of years in France, broke out into open warfare in 1562, but on March 19, 1563, the Peace of Amboise was signed with the Huguenots. On July 28 of that year, Le Havre was taken from the English, and in 1564 an Anglo-French peace was arranged at Troyes. Charles himself was declared of age in 1563, and the country remained at peace until 1567, when the conflict between Huguenot and Catholic was renewed. After the Battle of St-Denis, in which the Catholic leader, Duc Anne de Montmorency, was killed, another peace was arranged (1568), but a dispute over Huguenot strongholds led to a third war within a few months. Despite the jealousy of Charles, Catherine, who remained the dominant figure of the reign, placed his brother, the duke of Anjou (later Henry III), at the head of the royal army. The Huguenots were defeated at Jarnac and Moncontour in 1569, and in the following year peace was concluded at St-Germain. The terms were fairly favorable to the Huguenots, and what was at

first an uneasy truce seemed likely to develop into real peace with the arrangement of a marriage between the Protestant king of Navarre (later Henry IV of France) and Margaret of Valois, Charles' sister. But the marriage, which took place on Aug. 18, 1572, and drew many Huguenots to Paris, was the prelude to a fourth war. Under Catherine's influence a plot was formed to kill the great Huguenot leader, Admiral Gaspard de Coligny. The first attempt, made on August 22, failed, but much suspicion was aroused, and Catherine and others persuaded Charles to strike at all the Huguenots. On August 24 began what has become known as the Massacre of St. Bartholomew. Coligny and thousands of other Huguenots were killed in Paris and the provinces. (See also SAINT BARTHOLOMEW, MASSACRE OF.) Another peace was arranged in 1573, but a fifth war was in progress when Charles died, without legitimate male heirs, in the following year.

CHARLES X (known until his accession as CHARLES PHILIPPE, COMTE D'ARTOIS), king of France: b. Versailles, France, Oct. 9, 1757; d. Görz, Austria, Nov. 6, 1836. The grandson of Louis XV and son of the Dauphin Louis, he was the younger brother of Louis XVI and Louis XVIII. After the destruction of the Bastille in 1789, he left France as one of the first émigrés, whose leader he became. When Louis XVI accepted the Constitution of 1791, he invited his brother to return, but Charles refused, and the Legislative Assembly, after removing his name from the civil list, confiscated his property in 1792. When war broke out, he acted in conjunction with the Austrian and Prussian armies on the Rhine. In 1795 he participated in an English expedition to Brittany, but soon withdrew and, abandoning the rebels of the Vendée, went to England and then to Scotland, where he lived for several years at Holyrood Palace, Edinburgh. Following the abdication of Napoleon in 1814, Charles returned to France as lieutenant general of the restored kingdom. During the reign of his brother, Louis XVIII, he was the leader of the ultraroyalist party. Succeeding to the throne in 1824, he gained a momentary popularity by abolishing press censorship, but reactionary measures soon followed, and a clash with the liberal elements became inevitable. In an attempt at a coup d'état, the king, on July 25, 1830, promulgated a celebrated series of ordinances, decreeing (1) dissolution of the newly elected Chamber of Deputies; (2) abolition of the freedom of the press; (3) alteration of the electoral laws to favor wealthy citizens; and (4) new elections. A revolution thereupon broke out in Paris, and Charles was driven from the throne. After abdicating formally (August 2) in favor of his grandson, Henri, duc de Bordeaux (later comte de Chambord), Charles went into exile. He revisited England, resumed for a short time his residence at Holyrood Palace, and then went to Prague. His last years were spent in Görz, Austria (now Gorizia, Italy).

CHARLES (called CHARLES THE BOLD; FR. CHARLES LE TÊMÉRAIRE; until his accession, COMTE DE CHAROLAIS), duke of Burgundy: b. Dijon, Burgundy, Nov. 10, 1433; d. Nancy, Lorraine, Jan. 5, 1477. The son of Duke Philip the Good, he became comte de Charolais in 1452, and succeeded his father in 1467. An implacable enemy of Louis XI, Charles joined the League of the

Public Weal (1464-1465) and defeated the king. Immediately after he became duke, he engaged in a war with the citizens of Liège, whom he conquered and treated with extreme harshness. Having been obliged by a rebellion to restore to the citizens of Ghent the privileges taken from them by Philip, he revoked (1469) his concessions, had the leaders of the insurrection executed, and imposed a large fine on the city.

Meanwhile, learning that the people of Liège, instigated by Louis, had rebelled once more (1468), he compelled the king to march with him against the city, which was taken by storm and abandoned to the fury of the soldiers. These successes made the duke inflexible, but as his treatment of his opponents became increasingly severe, the forces which led to his ultimate destruction were aroused.

Charles had married (1468) Margaret, sister of Edward IV of England, and in 1470 he gave the exiled king the money and ships which enabled him to regain his throne. In 1471 the war between the duke and Louis XI was renewed. Charles completed the conquest of Lorraine by taking Nancy in 1475, and then turned against the Swiss. Early in the following year he took the city of Grandson and executed its garrison of 800 men, but this cruelty was soon avenged by the signal victory which the Swiss won nearby on March 2, 1476. After raising a new army, Charles returned to Switzerland, but was defeated once more, at Morat, on June 22. René II, duke of Lorraine, who had fought with the Swiss, led the victors to Nancy, which surrendered to him on October 7. Charles marched to Lorraine, and on Jan. 5, 1477, the two armies met at Nancy. The wings of the Burgundian force were broken through and scattered, and the center, commanded by Charles, was attacked in front and flanked. Beaten and carried along with his retreating army, the duke was thrown from his horse into a ditch, where he was killed by a lance thrust. Although his daughter and heiress, Mary of Burgundy, continued the struggle against Louis XI, she was unsuccessful, and the duchy was annexed to the French crown (1482).

CHARLES (called **CHARLES THE GOOD**; Fr. **CHARLES LE BON**), count of Flanders: b. ?1083; d. Bruges, Flanders, March 2, 1127. The son of King Canute IV of Denmark and Adela, daughter of Robert I, count of Flanders, he was raised in Flanders after Canute's assassination (1086). His cousin, Baldwin VII (d. 1119), willed the countship to him, and after a brief civil war his succession was recognized. He refused the crown of Jerusalem and also the nomination to the imperial crown after the death of Henry V (1125), being content to rule Flanders with justice and clemency. His reign was brought to an untimely close by his murder in the Church of St. Donat, Bruges.

CHARLES I, duke of Lorraine: b. ?950; d. Orléans, France, ?992. The younger son of the Frankish king Louis IV, he was given Lower Lorraine as a duchy by Emperor Otto II in 977. On the death of Louis V (987), the last Carolingian sovereign of France, Charles claimed the crown, for which he fought Hugh Capet. His armies were defeated, however, and he himself was betrayed into Hugh's hands (991) and imprisoned at Orléans, where he remained until his death.

CHARLES II (or **I**; called **CHARLES THE BOLD**), duke of Lorraine: b. 1365; d. Jan. 25, 1431. The son of John I of Lorraine, he succeeded his father as duke in 1391. Neglecting the affairs of his duchy, he spent his life in warfare in Flanders, Hungary, and elsewhere, and was succeeded by René I, king of Naples, husband of his daughter Isabella.

CHARLES III (or **II**; called **CHARLES THE GREAT**), duke of Lorraine: b. Nancy, Lorraine, Feb. 18, 1543; d. there, May 14, 1608. The son of Duke Francis I, he succeeded his father in 1545. From 1552 to 1559 he lived at the court of King Henry II of France, whose daughter Claude he married (1559). Returning to Lorraine in 1560, he devoted himself to the welfare of his territory. He established several new towns and built a number of imposing structures in Nancy. As a member of the Holy League, he was an active participant in the French religious wars.

CHARLES IV (or **III**), duke of Lorraine: b. Nancy, Lorraine, April 5, 1604; d. Sept. 18, 1675. The son of Duke Francis II, he succeeded to the duchy on his father's abdication in 1624, and obtained the Duchy of Bar through marriage with his cousin, Nicole. Forced to abdicate by Armand Cardinal de Richelieu in 1634, he entered the service of Emperor Ferdinand III, for whom he fought at Nördlingen. His duchies were restored in 1641, but were seized again three years later. After the Peace of Westphalia (1648), Charles entered Spanish service. Subsequently he fought for the Fronde (q.v.). Because of various intrigues he was imprisoned by the Spanish from 1654 to 1659, when his duchies were restored once more. He lost them 10 years later, however, and died in exile.

CHARLES V (or **IV**; also known as **CHARLES LEOPOLD**), duke of Lorraine: b. Vienna, Austria, April 3, 1643; d. Wels, Austria, April 18, 1690. The nephew and heir of Duke Charles IV, he attempted to occupy Lorraine on his uncle's death (1675), but was unsuccessful in a two-year struggle against the forces of Louis XIV of France, and despite years of negotiation never obtained his duchy. Turning to a military career, he became a general and later a field marshal in imperial service. In 1683, with King John III Sobieski of Poland, he broke the Turkish siege of Vienna, and four years later he defeated the Turks decisively in the Second Battle of Mohács (actually fought at Harkány, Hungary). In the War of the Palatinate, which began in 1688, Charles was in command of the imperial forces fighting Louis XIV, but he died while on his way from Vienna to the front.

CHARLES (in full **CHARLES ALEXANDER**; Ger. **KARL ALEXANDER**), prince of Lorraine: b. Lunéville, Lorraine, Dec. 12, 1712; d. Tervueren, Austrian Netherlands, July 4, 1780. The youngest son of Duke Leopold of Lorraine and grandson of Duke Charles V, he was trained for a military career. He fought the Turks in 1738-1739, and in the following year, at the outbreak of the First Silesian War, was made a field marshal by Maria Theresa of Austria, wife of his brother, Duke Francis Stephen (later Emperor Francis I). Although he distinguished himself as a military commander, Charles was defeated by Frederick the Great of Prussia at Chotusitz (1742). In

1744 he married Maria Ann of Austria, sister of Maria Theresa, who made the couple joint governors general of the Austrian Netherlands (now Belgium). When the Second Silesian War (1744-1745) broke out, Charles made a brilliant crossing of the Rhine and invaded Lorraine, but was forced to withdraw in order to march against Frederick in Silesia. After expelling the Prussians from Bohemia, he was defeated by them (1745) at Hohenfriedberg and Soor. In the following year, as commander in the Netherlands, he was defeated by Marshal Saxe at Rocourt. Recalled to military duty in the Seven Years' War, he defeated the Prussians at Breslau in 1757, but was in turn crushingly defeated by Frederick at Leuthen later that year. Relieved of his command, he served as military adviser in Vienna until 1763, when he was reappointed governor general at Brussels, serving in this post until his death. Charles introduced many reforms in the government of the Austrian Netherlands, and did much to aid the welfare of the people there.

CHARLES, the name of seven rulers of Germany. See CHARLES I to CHARLES VII, Holy Roman emperors.

CHARLES (Ger. KARL), grand duke of Baden: b. Karlsruhe, Baden, June 8, 1786; d. Rastatt, Dec. 8, 1818. The grandson and successor of Grand Duke Charles Frederick (d. 1811), he aided Napoleon, whose adopted daughter, Stéphanie de Beauharnais, he married in 1806. After the French defeat at Leipzig in 1813, Charles sided with the Allies, and two years later he made Baden a member of the Germanic Confederation. In 1818, shortly before his death, he granted a liberal constitution to the grand duchy.

CHARLES, the name of two grand dukes of Mecklenburg-Strelitz.

CHARLES (in full CHARLES LOUIS FREDERICK; 1741-1816) served as governor of Hannover from 1776 to 1786, and six years later became duke of Mecklenburg-Strelitz. He joined the Allied coalition against Napoleon, and in 1815 his duchy was made a grand duchy.

CHARLES (in full CHARLES FREDERICK AUGUSTUS; 1785-1837), son of the preceding, distinguished himself as an officer in the Prussian Army in the wars against Napoleon. He succeeded his father as grand duke in 1816, but remained in Prussian service, rising to the rank of general in 1825, and becoming president of the Council of State in Berlin two years later.

CHARLES I (in full CHARLES FREDERICK ALEXANDER), king of Württemberg: b. Stuttgart, Württemberg, March 6, 1823; d. there, Oct. 6, 1891. The only son of King William I of Württemberg, he married Grand Duchess Olga, daughter of Nicholas I of Russia, in 1846, and succeeded his father as king in 1864. He sided with Austria against Prussia in 1866, but joined the other German states in the Franco-Prussian War in 1870. During his reign a number of reforms were introduced in Württemberg.

CHARLES, the name of two dukes of Württemberg.

CHARLES (I) ALEXANDER (1684-1737) served in the Austrian Army during the War of the Spanish Succession, and against the Turks in 1716-1718. He succeeded to the duchy in 1733.

CHARLES (II) EUGENE (1728-1793), son of the preceding, succeeded his father as duke in 1737, and was declared of age seven years later. His long reign was generally tyrannical. He founded the Karlschule (later known as the Akademie) in Stuttgart.

CHARLES I, Holy Roman emperor. See CHARLEMAGNE.

CHARLES II (called CHARLES THE BALD; Fr. CHARLES LE CHAUVÉ), Holy Roman emperor and, as CHARLES I, king of France: b. Frankfurt am Main, Germany, June 13, 823; d. Brides-les-Bains, France, Oct. 6, 877. He was the son of Emperor Louis I and his second wife, Judith of Bavaria. Before his birth his father had divided the empire, to take effect after his death, among his three elder sons, Pepin (Pepin I, king of Aquitaine, d. 838), Lothair (Emperor Lothair I), and Louis (Louis II, king of Germany). The redivision of the inheritance to provide a share for Charles provoked a civil war in 838. On Louis I's death, in 840, Charles became king of what is now France, but he found himself confronted with two enemies—Lothair, who, as eldest son, claimed the whole of the Frankish empire of Charlemagne; and Pepin's son, Pepin II, who asserted his right to inherit his father's sovereignty over Aquitaine. With the aid of his half brother Louis, Charles defeated Lothair and Pepin at Fontenoy, France, in 841. Two years later, by the Treaty of Verdun, the empire was divided among the three brothers, Louis receiving Germany; Lothair, Lotharingia (Lorraine) and Italy; and Charles, most of what is now France. (Pepin II was dispossessed by the treaty. Though reinstated as king of Aquitaine in 845, he was again dispossessed in 850.) As king of France, Charles was faced by constant raids by the Normans, who sacked Bordeaux, Rouen, Orléans, and part of Paris. In 875, on the death of his nephew, Emperor Louis II (son and successor of Lothair), Charles invaded Italy and had himself crowned emperor and, in the following year, king of Italy. He thereby provoked the hostility of his brother, Louis II of Germany, who ravaged Champagne. Charles' death occurred while he was returning from an abortive expedition to Italy to aid Pope John VIII against the Saracens.

CHARLES III (called CHARLES THE FAT; Fr. CHARLES LE GROS), Holy Roman emperor and, as CHARLES II, king of France: b. 839; d. Neudingen, near Donaueschingen, Germany, Jan. 13, 888. The son of King Louis II of Germany, he was king of part of Germany from 876 to 887. In 881 he was crowned emperor by Pope John VIII, and three years later he ascended the French throne, the rights of his cousin, Charles the Simple (later King Charles III), not being recognized because of his youth. In 886, Charles the Fat was forced to sign a treaty with the Normans, and in the following year he was deposed by Arnulf, who became emperor, while Eudes, count of Paris, became king of France.

CHARLES IV (known also as CHARLES OF LUXEMBURG), Holy Roman emperor: b. Prague, Bohemia, May 14, 1316; d. there, Nov. 29, 1378. The son of John of Luxembourg, king of Bohemia, he spent his youth in France, where his father aided King Charles IV and Philip VI, and he

fought at the Battle of Crécy (1346). His father was killed in that battle, and Charles inherited the Kingdom of Bohemia. In 1346, by agreement with Pope Clement VI, he was chosen emperor by five electors to succeed the deposed Louis IV, and he hoped to occupy the imperial throne without opposition. Louis fought against him, however, and the princes of the empire regarded Charles as a servant of the pope. Even after Louis' death (1347) he encountered opposition, but his marriage to Anna, daughter of Rudolf, count of the Palatinate, and various concessions to his enemies paved the way for his unanimous election as emperor and his coronation at Aachen in 1349. In 1354, Charles went to Italy, where he virtually abandoned all imperial claims. After his coronation as king of Italy at Milan (1355), he confirmed the Visconti in their possessions, and he annulled the acts of his grandfather, Emperor Henry VII, against Florence. He received the imperial crown at Rome (1355), and, refusing the request of some Romans to claim the city, renounced all sovereignty over Rome, the Papal States, Naples, Sicily, Sardinia, and Corsica. Returning to Germany in 1356, Charles issued the celebrated Golden Bull (q.v.) at Nurnberg. In 1365 he was crowned king of Burgundy at Arles.

In general, Charles neglected the empire, preferring to increase the power and prestige of Bohemia, which attained a high degree of prosperity under his rule. He rebuilt and embellished the city of Prague, published a new code of laws for the kingdom, and, in 1348, founded the University of Prague. Meanwhile, there was considerable unrest in other parts of the empire. Despite the emperor's opposition, the towns and cities of Swabia formed the Swabian League for their protection. The reign was marred by a terrible persecution of the Jews.

CHARLES V, Holy Roman emperor and, as CHARLES I, king of Spain: b. Ghent, Flanders, Feb. 24, 1500; d. San Jerónimo de Yuste, near Plasencia, Spain, Sept. 21, 1558. The son of Philip of Burgundy (later Philip I of Castile), and the grandson of Emperor Maximilian I and of Ferdinand and Isabella of Spain, he inherited Burgundy and the Netherlands on the death of his father in 1506. He was educated in Flanders under the care of Guillaume de Croy, seigneur de Chièvres. On the death of Ferdinand in 1516, Charles became King of Spain, Francisco Cardinal Jiménez de Cisneros serving as regent until the young monarch's arrival in the peninsula in the following year. On the death of Maximilian in 1519, Charles was elected emperor, and he left Spain to take possession of his new dignity, for which he had to contend with King Francis I of France. His coronation took place at Aachen in 1520. Germany was then in the midst of the Reformation, and in the following year the emperor held a Diet at Worms, at which Martin Luther appeared, with a safe-conduct from Charles, and defended his cause with energy and boldness. Charles kept silent, but after Luther's departure the Edict of Worms, outlawing the reformer and his followers, was issued. Meanwhile, during Charles' absence, several revolts were put down in Spain: that of the *comuneros* (commoners or townsmen) in 1521; that of the *germanías* in 1523; and that of the Moriscos in 1525.

Within a few years the growing power of Charles had become a source of uneasiness to most other European rulers. In 1526, Pope Clem-

ent VII placed himself at the head of a league of the principal Italian states against the emperor (Holy League of Cognac). Imperial troops under Constable Bourbon (Duc Charles de Bourbon) took Rome by storm in 1527, sacked the city, and made the pope himself prisoner. Henry VIII of England now allied himself with Francis against Charles, who accused the French monarch of having broken his word. The war was terminated in 1529 by the Peace of Cambrai, under conditions favorable to the emperor. In the following year, Charles was crowned king of Lombardy and Roman emperor by the pope at Bologna. At the Diet of Augsburg (1530), he seemed desirous of reconciling the various parties, but, failing to do so, issued a decree against the Protestants, which they countered by the formation of the League of Schmalkalden in 1531. In general, however, Charles practiced moderation toward the Protestants of Germany, and the Protestant rulers furnished contingents when he assembled an army against the Turks. Having compelled Sultan Suleiman I to retreat in 1532, he undertook in 1535 an expedition against the pirates of Tunis, reinstated the dey, and released 20,000 Christian slaves.

Charles' policy was to reconcile the two great religious parties, and to this end he alternately threatened and courted the Protestants. After negotiations failed, however, the Schmalkaldic War broke out in 1546. The emperor declared the heads of the league under the ban of the empire, raised an army, and obtained an early advantage over his enemies. John Frederick, the elector of Saxony, was taken prisoner at the Battle of Mühlberg (1547), and he saved his life only by renouncing his electorate and his hereditary estates, but remained a prisoner. Another Protestant leader, Philip the Magnanimous, landgrave of Hesse, was also deprived of his freedom. After dissolving the League of Schmalkalden, Charles again occupied himself with his plan for uniting all religious parties, and for this purpose issued the Augsburg Interim (1548), which proved as fruitless as the measures he had proposed at the Diet of Augsburg. Neither was he successful in securing the imperial crown for his son, Philip. Moreover, in 1551, Maurice, duke of Saxony, whom Charles had made elector, formed a league, which was joined by Henry II of France, Francis' successor. At this time, Charles was superintending the deliberations of the Council of Trent and formulating plans for war against France and the Turks. He was expecting the aid of Maurice, when that prince suddenly appeared at the head of an army (1552) and invaded the Tirol, while Henry entered Lorraine. The emperor was nearly surprised at Innsbruck. The Council of Trent was adjourned, and the Protestants were able to dictate the conditions of the Treaty of Passau (1552). John Frederick and Philip the Magnanimous were freed. Charles was not more successful in Lorraine. He was unable to recover Metz, which was defended by François de Lorraine, 2d duc de Guise. In Italy he lost Siena by a revolt. He withdrew to Brussels, where for several months he lived in seclusion, so that the report of his death was spread over Europe. His last efforts were made against France, which constantly repelled his assaults. The Peace of Augsburg (1555) confirmed the Treaty of Passau, and gave Protestants equal rights with Roman Catholics.

Charles, seeing all his plans frustrated, resolved to transfer his hereditary estates to Philip

(later King Philip II of Spain). In 1554 he relinquished Naples to his son, and in the following year, at a meeting of the Estates of the Netherlands at Louvain, he conferred on Philip the sovereignty over the Netherlands as well. He relinquished the imperial crown to his brother, Frederick I, in 1556, and in the same year abdicated as king of Spain in favor of Philip. Reserving for himself a pension of 100,000 ducats, he retired in 1557 to the Monastery of San Jerónimo de Yuste in Extremadura, where he lived a life of religious devotion until his death.

CHARLES VI, Holy Roman emperor and, as **CHARLES III**, king of Hungary: b. Vienna, Austria, Oct. 1, 1685; d. there, Oct. 20, 1740. The second son of Emperor Leopold I, he was destined by his father for the Spanish throne. The last Habsburg king of Spain, Charles II, had no children, and there were several candidates to succeed him. Disregarding the claims of the Austrian Habsburgs, he made a will naming as his heir Philip, duke of Anjou, grandson of King Louis XIV of France. When Charles II died, on Nov. 1, 1700, Philip accordingly took possession of the vacant throne, with the title of Philip V. In the war which followed, known as the War of the Spanish Succession (see **SUCCESSION WARS**), Philip was supported only by France, while England and Holland united against him in an alliance soon joined by Prussia, Portugal, and Savoy. Charles was proclaimed king of Spain at Vienna in 1703. In January of the following year, with 12,000 men, he sailed from England to Spain, which was almost wholly occupied by the French. Landing in Catalonia, he made himself master of Barcelona, but was soon besieged there by Philip. With a small garrison he held out until a long-expected English fleet appeared, compelling the French to raise the siege. In the ensuing struggle for Spain, Charles met with alternate reverses and successes. Twice he reached Madrid, and twice he was driven from the city. On the first occasion, in 1706, he had himself proclaimed king under the title Charles III. In 1711, after he had been compelled for a second time to retreat to the walls of Barcelona, he learned of the death of his brother, Emperor Joseph I, and of his own succession to the Austrian and Hungarian dominions. Returning to Germany, he was informed that, at the suggestion of Eugene, prince of Savoy, he had also been elected emperor. His coronation took place at Frankfurt am Main in December 1711, and in the following year he received, at Pressburg (now Bratislava), the crown of Hungary. At the same time, despite the growing coolness of his allies (who did not like to see so much power united in the same hands), he retained the empty title of king of Spain. He continued to prosecute the war, but he was unable to prevent the allies from concluding a peace with France at Utrecht in 1713, and in the following year he was obliged to sign the Treaty of Rastatt. By this treaty he was confirmed in the possession of Naples, Milan, Sardinia, and the former Spanish Netherlands. Meanwhile, in 1713, to secure the succession to his dominions of his daughter, Maria Theresa, in default of male heirs, he issued the Pragmatic

Sanction (q.v.), which he induced the powers to guarantee.

When, in 1733, the succession to the Polish throne was disputed following the death of Augustus II, Charles, with Russia, supported the claims of Augustus' son, while France and Spain declared themselves for Stanislas I Leszczyński. The ensuing War of the Polish Succession, which lasted until 1735, resulted in the Austrian loss of the Two Sicilies and part of the Duchy of Milan. Austria received Tuscany in exchange for Lorraine, and obtained Parma. Two years later, Charles' alliance with Russia involved him in a war with the Turks. His troops invaded Serbia without a declaration of war, and occupied Niš. The Turks increased their forces, however, and obliged the emperor, after three unsuccessful campaigns, to sign the Treaty of Belgrade (1739), whereby Charles ceded to them Walachia and the Austrian portion of Serbia, with Belgrade.

CHARLES VII (**CHARLES ALBERT**; Ger. **KARL ALBRECHT**; known also as **CHARLES OF BAVARIA**), Holy Roman emperor: b. Brussels, Spanish Netherlands, Aug. 6, 1697; d. Munich, Bavaria, Jan. 20, 1745. He was the son of Maximilian II Emanuel, elector of Bavaria, who, at the time of Charles' birth, was governor of the Spanish Netherlands. His youth was spent at the imperial court, and in the war against the Turks (1714-1718) he commanded an army of auxiliaries sent by his father. In 1722 he married Maria Amelia, daughter of Emperor Joseph I, having previously renounced (with mental reservations) all rights which this marriage might give him to the succession to the Austrian throne. Four years later he succeeded his father as elector of Bavaria. Charles was one of the princes who protested against the Pragmatic Sanction (q.v.), guaranteed in 1732 by the Diet of Regensburg, and in consequence he concluded a defensive alliance with Saxony. After the death of Emperor Charles VI in 1740, he refused to acknowledge Maria Theresa as heir of the Habsburg dominions, founding his own claims to the succession on a will of Ferdinand I. In the ensuing War of the Austrian Succession (see **SUCCESSION WARS**), Charles was supported by France, and in 1741 he was recognized at Linz as archduke of Austria. The obstacles placed in his path by André Hercule Cardinal de Fleury, who did not wish the Austrian monarchy dismembered, as well as want of artillery and ammunition, prevented Charles from gaining possession of Vienna. He was able to take Prague (1741), however, and there he was crowned and proclaimed king of Bohemia. In the following year he was unanimously elected Holy Roman emperor and made a solemn entry into Frankfurt am Main, where he was crowned by his brother, Clement, archbishop of Cologne. This was the high point of Charles' fortunes, for the armies of Maria Theresa soon reconquered Upper Austria and overran Bavaria. Charles was forced to abandon Bohemia, and he fled to Frankfurt. An attack by Prussia on Maria Theresa permitted Charles to return to Munich in 1744. He was succeeded in the electorate by his son, Maximilian III Joseph.

CHARLES I (known also as **CHARLES ROBERT OF ANJOU** and **CAROBERT**), king of Hungary: b. 1288; d. July 16, 1342. The grandson of King Charles II of Naples, he claimed the crown of Hungary as the great-grandson of Stephen V.

After being crowned at Esztergom in 1301, however, he was forced to surrender the crown to Wenceslaus III of Bohemia. With the aid of Pope Boniface VIII, he determined to recover the crown, and in 1308 he was elected king by the Hungarian Diet. On June 15, 1309, he was enthroned at Buda, but his installation was not regarded as valid until he was crowned with the sacred crown of St. Stephen on Aug. 27, 1310. For the next two years he was faced with constant rebellions, finally defeating the rebels and establishing his authority at the Battle of Rozgony (June 15, 1312).

The founder of the Anjou line of Hungary, Charles established the power of the Hungarian royal house on a feudal basis. He encouraged trade, increased the privileges of the towns, imposed direct taxes, and raised Hungary to the rank of a major power, while at the same time enriching and civilizing the country. His successful ventures in foreign affairs culminated in 1339 in his marriage to Elizabeth, daughter of Ladislas I king of Poland, eventual succession to the Polish throne being secured to the son of this marriage, Louis I.

CHARLES II (known as **CHARLES OF DURAZZO**), king of Hungary. See **CHARLES III**, king of Naples.

CHARLES III, king of Hungary. See **CHARLES VI**, Holy Roman emperor.

CHARLES IV, king of Hungary. See **CHARLES I**, emperor of Austria.

CHARLES I (known as **CHARLES OF ANJOU**), king of Naples and Sicily: b. 1226; d. Foggia, Italy, Jan. 7, 1285. The son of King Louis VIII of France, he became count of Anjou and of Provence in 1246. Two years later, he accompanied his elder brother, Louis IX, on the Seventh Crusade, returning to France in 1250. With papal backing, he waged war on Manfred, king of the Two Sicilies, who was the leader of the Ghibelline faction in Italy, and in 1266 defeated him at the Battle of Benevento. Manfred was killed, and Charles succeeded him as king of Naples and Sicily. Two years later, Charles defeated and beheaded Manfred's nephew, Conradin, thereby removing the last open opposition to his rule. The reign of Charles in Sicily was marked by such cruelty that the French became universally detested on the island. Finally, on March 31, 1282, the Sicilians rose in arms and killed all the French in the town and neighborhood of Palermo. The signal for the rising was the tolling of the vesper bell, and the massacre is known in history as the Sicilian Vespers (q.v.). Two years later, Charles was driven from Sicily by Pedro III of Aragon, and he was unsuccessful in several attempts to regain the island.

CHARLES II (sometimes known as **CHARLES OF ANJOU**), king of Naples: b. 1246; d. Naples, Italy, May 5, 1309. The son of King Charles I of Naples and Sicily, he was captured by Pedro III of Aragon in a naval battle at Naples in 1284. In the following year, while still a prisoner, he succeeded to the throne of the Two Sicilies. King Edward I of England negotiated a peace in 1287, and in the following year Charles was released to become king of Naples only. With the aid of Pope Nicholas IV, he attempted to regain

Sicily, but the death of Alfonso III of Aragon (1291) and of the pope (1292) changed the situation. The new pope, Boniface VIII, attempted mediation and succeeded in negotiating a treaty. King Frederick II of Sicily refused to agree to the treaty, however, and was supported in his stand by his people. In the furious land and sea war (1296-1302) which followed, Charles was aided by his sons-in-law, Charles de Valois and James II of Aragon, but was unable to reconquer the island. In 1302 a new treaty was signed at Caltabellotta. By its terms, Charles relinquished his claims to Sicily, and he also gave his daughter, Leonora, in marriage to Frederick.

CHARLES III (known as **CHARLES OF DURAZZO** and **CHARLES OF ANJOU**), king of Naples and, as **CHARLES II**, king of Hungary: b. 1345; d. near Buda, Hungary, Feb. 17, 1386. The great-grandson of Charles II of Naples, he was adopted by Queen Joanna I, but was subsequently replaced in her favor by Louis I of Anjou. In 1381 he seized the crown of Naples. A year later he caused the death of his adopted mother, and from 1382 to 1384 he fought Louis. Crowned king of Hungary in 1385, he was soon faced by a rebellion. Taken prisoner, he was poisoned.

CHARLES IV, king of Naples and Sicily. See **CHARLES III**, king of Spain.

CHARLES, the name of three dukes of Parma of the Italian Bourbon line.

CHARLES I. See **CHARLES III**, king of Spain.
CHARLES II (in full **CHARLES LOUIS FERDINAND DE BOURBON**; 1799-1883), son of Louis de Bourbon, king of Etruria, and of Maria Luisa, daughter of King Charles IV of Spain, became duke of Parma in 1803. Four years later his abdication was forced by Napoleon. The Congress of Vienna gave Parma to Maria Louise, wife of Napoleon, and awarded the Duchy of Lucca to Maria Luisa, who served as regent for her son until her death in 1824. As duke of Lucca, Charles was at first a liberal ruler, but eventually he became eccentric and reactionary. On the death of Marie Louise in 1847, he was restored as duke of Parma, and he sold his interest in Lucca to Tuscany. When the revolutionary movement of 1848 reached Parma, Charles was forced to abdicate. This step was confirmed in 1849, and he retired to France.

CHARLES III (in full **CHARLES FERDINAND DE BOURBON**; 1823-1854), son of Charles II, placed Parma under martial law immediately after his accession, which followed his father's abdication in 1849. He closed the university and embarked on a policy of repression and persecution of liberal elements. A drunkard and a libertine, he died by assassination.

CHARLES I, king of Spain. See **CHARLES V**, Holy Roman emperor.

CHARLES II, king of Spain: b. Madrid, Spain, Nov. 11, 1661; d. there, Nov. 1, 1700. The son of King Philip IV and Mariana de Austria, he succeeded his father in 1665, his mother serving as regent until 1675. In this reign, Spain, which for nearly three centuries had been a leading European power, declined rapidly in influence and prestige. The king was a puppet alternately in the hands of the French and Austrian factions at his court, and the three wars which Spain

fought with France were a drain on the country's resources. Shortly before his death, Charles named as his successor Philip, duke of Anjou, grandson of Louis XIV of France, an act which led to the long and calamitous War of the Spanish Succession.

CHARLES III (known in his youth as **DON CARLOS OF BOURBON**), king of Spain and, as **CHARLES I**, duke of Parma, and **CHARLES IV**, king of the Two Sicilies (Naples and Sicily): b. Madrid, Spain, Jan. 20, 1716; d. Dec. 14, 1788. The elder son of King Philip V and his second wife, Elizabeth Farnese of Parma, he received Parma and Piacenza in 1731, with the title of duke of Parma. Three years later, with French support, he conquered the Two Sicilies and was proclaimed king. The first of the Neapolitan Bourbons, he reigned as Charles IV. (In the following year he renounced his rights in Parma and Piacenza to Austria, a decision confirmed by the Treaty of Vienna in 1738.) As ruler of the Two Sicilies, he began the program of internal reform which he would continue in Spain. On the death of his half brother, Ferdinand VI, in 1759, Charles became king of Spain and resigned the Two Sicilies to his third son, Ferdinand I. Two years later he signed the Third Family Compact with France, a step which, by drawing Spain into the Seven Years' War, resulted in the loss of Menorca and Florida under the terms of the Treaty of Paris (1763). He came close to warring with Great Britain over the Falkland Islands in 1771, and in 1779 joined France in alliance with the United States against Britain. By the Treaty of Versailles (1783), Spain recovered Menorca and Florida.

An ardent Francophile, Charles tried to force the people of Madrid to adopt French dress styles in 1766, causing riots from which he fled to Aranjuez, leaving the government in the hands of his prime minister, Pedro Pablo Abarca y Bolea, conde de Aranda. The expulsion of the Jesuits from Spain (1767) is attributed to Aranda. An enlightened despot, Charles instituted important financial and economic reforms and curbed the power of the Inquisition.

CHARLES IV, king of Spain: b. Naples, Italy, Nov. 12, 1748; d. Rome, Jan. 20, 1819. He was brought to Madrid in 1759, when his father, then king of the Two Sicilies, became king of Spain as Charles III. In 1765 he married Maria Louisa of Parma, and in 1788, on the death of his father, succeeded to the throne. Weak and vacillating, he was dominated by his wife and his ministers. Spain was unable to withstand French pressure, and in 1796 was drawn into war against Great Britain. Louisiana was sold to France in 1800, and two years later Trinidad was ceded to Britain. In 1805, Spain was again induced to join France against Britain, and later that year suffered a disastrous defeat at Trafalgar. The Francophile policy of the prime minister, Manuel de Godoy, who exercised great influence over the king and his wife, brought on a revolution in 1808, which enabled Napoleon to dethrone the Bourbons. The king abdicated at Aranjuez on March 19, in favor of his son, Ferdinand VII, who in turn was forced to abdicate by Napoleon on May 6. See **BAYONNE CONFERENCE** (1808). Charles, who had repudiated his own abdication, was also forced to cede his right to the throne, and a month later, on June 6, Napoleon's brother,

Joseph Bonaparte, became king of Spain. Retiring to Compiègne, where he enjoyed a pension from Napoleon, Charles subsequently moved to Rome, where he spent his last years.

CHARLES I, king of Navarre. See **CHARLES IV**, king of France.

CHARLES II (called **CHARLES THE BAD**; **Fr. CHARLES LE MAUVAIS**), king of Navarre: b. 1332; d. Jan. 1, 1387. He succeeded his father, Philip, as count of Évreux, in 1343, and his mother, Queen Joanna, on the throne of Navarre in 1349. Three years later he married Jeanne, daughter of John II of France, and held a complicated but strong claim to the French throne by both inheritance and marriage. A man of ability, he was completely unscrupulous and earned his epithet "the Bad" by his thoroughly cruel behavior. He disputed King John's claim to parts of Normandy and Angoulême, and in 1356-1357 was imprisoned by the king. In 1358 he became captain general of Paris, and for two years he contended with the dauphin (later Charles V), who was serving as regent of France during John's captivity in England. He was defeated by the French in 1364, but subsequently renewed the struggle, and he also made trouble in Spain.

CHARLES III (called **CHARLES THE NOBLE**), king of Navarre: b. 1361; d. Olite, Spain, Sept. 7, 1425. The eldest son of Charles II of Navarre, he married Leonora, daughter of Henry II of Castile, in 1375, and succeeded to his father's kingdom in 1387, later being made duke of Nemours. He restored Cherbourg to France, and attempted to pacify the rival French factions. His reign was marked by considerable progress. He built canals and deepened rivers in Navarre, and made many other improvements. His two sons having predeceased him, he willed his kingdom to his daughter Blanche, wife of John II of Aragon, and mother of Charles, prince of Viana.

CHARLES (sometimes known as **CHARLES IV**, king of Navarre, prince of Viana: b. April 19, 1421; d. Barcelona, Spain, Sept. 25, 1461. He was the son of Blanche, heiress of Charles III of Navarre, and of King John II of Aragon. Although Navarre was bequeathed to Charles, and his right to succeed recognized by the Cortes, John seized the government in 1441 and banished his son. The king's second marriage, to Juana Henríquez, produced another son, later Ferdinand II of Aragon, and the new queen attempted to oust her stepson completely. As a result, civil war broke out, and in 1452 Charles was defeated and imprisoned. On his release, he promised not to take title to Navarre until his father's death, and went into exile in Italy. Eventually becoming reconciled with his father, he returned to Navarre in 1459, but was once more imprisoned. A new insurrection began, and John was forced to yield. He released his son and recognized his succession, but Charles died soon thereafter, perhaps poisoned by his stepmother. A cultivated man, he was the author of poems and chronicles, among them a history of the kings of Navarre.

CHARLES VII, king of Sweden: d. Visingö, Lake Vättern, Sweden, 1167. The son of King Sverker, he came to the throne in 1161 with the title of king of Swedes and Goths. Although he is styled the seventh Swedish king of his

name, he was the first historical King Charles, his six supposed predecessors being of doubtful authenticity. He fought against the Russians in 1164, and three years later was assassinated by Knut Eriksson, son of Eric IX.

CHARLES VIII (known as **KARL KNUTSSON**), king of Sweden and Norway: b. ?1408; d. Stockholm, Sweden, May 15, 1470. He took part in the revolt against the Danes led by Engelbrekt Engelbrektsson in 1434, and after the latter's death became the leader of the Swedish nationalists. Elected regent of Sweden by the nobles in 1436, he served until 1440, when the union with Denmark was re-established. He was king of Sweden from 1448 to 1457, from 1464 to 1465, and from 1467 to 1470, and king of Norway from 1449 to 1450. During years of alternating kingship and exile he fought a war with Denmark (1463-1470).

CHARLES IX, king of Sweden: b. Stockholm, Sweden, Oct. 4, 1550; d. Nyköping, Oct. 30, 1611. The third son of Gustaf Vasa, he became duke of Södermanland on his father's death in 1560. He participated in the revolt which brought about the deposition of his eldest brother, Eric XIV, in 1568, and he opposed the policies of his second brother, John III. When John died in 1592, Charles became regent for his brother's son, King Sigismund (Sigismund III of Poland), serving until 1594, when his nephew came from Poland to be crowned. A staunch Protestant, Charles opposed efforts to re-establish the Roman Catholic Church in Sweden. In 1598 he defeated Sigismund at Stångebro, Linköping, and in the following year was made hereditary prince of Sweden. He assumed the title of king in 1604 and ruled until his death. During his reign trade and mining were fostered, and the power of the nobles was curbed.

CHARLES X, king of Sweden. See **CHARLES X GUSTAVUS**.

CHARLES XI, king of Sweden: b. Stockholm, Sweden, Nov. 24, 1655; d. there, April 5, 1697. The son of Charles X Gustavus, he succeeded his father on the throne in 1660, and until 1672 the country was governed by a corrupt regency. As an ally of France in the Second Dutch War, Charles was defeated in several battles in 1675 and 1676 and lost some territory, but it was all recovered under the terms of the Peace of Nijmegen (1678-1679). During the regency the power of the nobles had been greatly increased, and in 1680 the king initiated a program of confiscation of large estates called the Great Reduction. Within two years he was almost an absolute monarch, but in general he used his power wisely. He founded the University of Lund, reorganized the army and navy, and strengthened public finance.

her. Accordingly, in 1699, Frederick IV of Denmark, Augustus II of Poland, and Peter I of Russia concluded an alliance which resulted in the Great Northern War (1700-1721). Danish troops invaded the territory of Frederick IV, duke of Holstein-Gottorp, Charles' brother-in-law. Swiftly retaliating, Charles invaded Denmark and forced the Danes to make peace at Travendal (1700). The attacks of Augustus and Peter remained to be repelled. The former was besieging Riga, while the latter menaced Narva and the country around the Gulf of Finland. Without returning to his capital (which in fact he never revisited), Charles had 20,000 men transported to Livonia and went to meet the Russians, whom he found over 40,000 strong in a fortified camp under the walls of Narva. On Nov. 20, 1700, a force of 8,000 Swedes placed themselves in battle order, under the fire of the Russians, and the engagement began. In less than a quarter of an hour the Russian camp was taken by storm. Most of the Russians were killed or drowned in the Narova (Narva) River, and the rest were taken prisoner or dispersed. Charles then crossed the Dvina River and drove the Saxon troops of Augustus from the eastern Baltic States. In 1702, the Swedes gained a brilliant victory at Kliszów and took Warsaw. Two years later, Charles dethroned Augustus and made Stanislas I Leszczyński king of Poland in his stead, and in 1706 he dictated the conditions of peace at Altranstädt.

Charles then set out to conquer the Russians. In August 1707, he left Saxony with 44,000 Swedes, while 6,000 remained behind to protect Stanislas. Although Charles moved at first toward Moscow, he changed his plan when he reached Smolensk, at the suggestion of the Cossack hetman, Ivan Stepanovich Mazepa, and proceeded to the Ukraine, where he hoped that the Cossacks would join him. Peter laid waste the Cossack country, however, and Mazepa could not procure the promised aid. Difficult marches, lack of provisions, perpetual attacks by the enemy, and severe cold weakened Charles' army. Then, as the king was about to invest the well-stocked city of Poltava, Peter appeared with 50,000 men. In reconnoitering, Charles was seriously wounded in the thigh, and in the decisive battle, which took place on June 28, 1709, he was obliged to issue his commands from a litter without being able to encourage his soldiers by his presence. The Swedes yielded to superior force, and the enemy gained a complete victory. Charles himself, together with Mazepa, fled with a small guard and finally found refuge in Turkish territory, at Bendery, Moldavia.

While the regency which was acting in Stockholm in the king's absence took measures for the defense of Swedish territory, Charles negotiated with Sultan Ahmed III and, in 1711, induced the Turks to declare war on Russia. The armies met on the banks of the Prut River in July. After the Turkish forces had surrounded the Russians, Peter was able to procure a peace (Treaty of the Pruth) in which Charles' interests were entirely neglected. The king made new plans and endeavored to induce the Turks to reopen hostilities, but Russian agents at the Porte were active against him, claiming that Charles wished to make himself, through Stanislas, master of Poland in order to attack the Turks. The Porte ordered the seraskier of Bendery to compel Charles to leave Turkish territory. If he refused, he was

fall
 throne and was declared of age by the Estates.
 Sweden's neighbors had become alarmed at her
 growing power, and the youth of the new king
 made this seem a favorable time to move against

¹ All dates in this article are Old Style.

to be brought to Adrianople (now Edirne). Unaccustomed to obeying others and apprehensive of being surrendered to his enemies, Charles determined to defy the Porte with the few hundred men remaining with him. When, on Feb. 1, 1713, his residence near Bendery was attacked by the Turks, he put up a dogged resistance. The house caught fire and he was about to abandon it when, his spurs becoming entangled, he fell and was taken prisoner. The Turks removed him from Bendery to Dimotika, where he remained for over a year. Then, escaping in disguise, he made an 80-day journey through hostile territory, reaching Stralsund, Prussia, then in Swedish hands, on Nov. 11, 1714. A combined army of Danes, Saxons, Prussians, and Russians invested the city, but although Charles defended it bravely, he was obliged to surrender the fortress on Dec. 13, 1715.

Proceeding to Lund, Charles took measures to defend the Swedish coast. Then, to recover his fortunes, he raised a new army of 20,000 men and decided, in 1717, to attack Norway. Part of the country had been conquered, and he was besieging Fredrikshald (now Halden) when, while inspecting the trenches before the fortress, he was killed by a bullet.

With Charles' death, Sweden ceased to be an imperial power. During his reign all the Swedish possessions except Finland were lost. The Great Northern War had passed through three stages: a war of defense; then a war of aggressions; and, finally, a struggle for national existence. Although Charles' ambitions had cost his country many lives and much territory, his people remained loyal to him and revered his memory.

Consult Godley, E. C., *Charles XII of Sweden* (London 1928).

CHARLES XIII, king of Sweden and Norway: b. Stockholm, Sweden, Oct. 7, 1748; d. there, Feb. 5, 1818. The second son of King Adolphus Frederick, he was trained as a naval officer. On his father's death, in 1771, he was recalled to Sweden from a tour of Europe, and in the following year played an important part in the bloodless revolution by which his brother, King Gustaf III, obtained control of the government. The king then appointed him governor general of Stockholm and duke of Södermanland. During the war with Russia of 1788–1790, Charles commanded the fleet and defeated the Russians in the Gulf of Finland. He was then appointed governor general of Finland. In 1792, following the assassination of Gustaf III, he became head of the regency which governed during the minority of Gustaf's young son, Gustaf IV. While uniting with Denmark to protect navigation, he was able to keep Sweden at peace and in 1796 relinquished control to his nephew, who had come of age. Gustaf IV was a weak king, whose decisions on foreign policy finally resulted in the Russian conquest of Finland. Accordingly, in 1809, he was deposed by a revolution and Charles was made regent and, on June 20, king of Sweden. The new monarch came to the throne at a very critical time. Although the Peace of Fredrikshamn (Sept. 17, 1809) gave Finland to Russia, it afforded Sweden the tranquillity necessary for repairing the country's heavy losses. Charles signed a new constitution, which restored a limited monarchy, and applied himself to the problem of succession to the throne. Childless, he had adopted as his heir Charles August (known also

as Christian), prince of Schleswig-Holstein-Sonderborg-Augustenburg, but the latter died in 1810. In August of that year, Marshal Jean Baptiste Bernadotte was elected by the Estates to replace him. Charles' prudent conduct during the war between France and Russia in 1812–1813 procured for Sweden, by the Treaty of Kiel of 1814, indemnification for the loss of Finland by the acquisition of Norway.

CHARLES XIV, king of Sweden and Norway. See **CHARLES XIV JOHN**.

CHARLES XV, king of Sweden and Norway: b. Stockholm, May 3, 1826; d. Malmö, Sept. 18, 1872. The son of King Oscar I, he succeeded his father on the throne in 1859. A liberal and popular ruler, he made important reforms in communal, ecclesiastical, and criminal law. In 1866 the Riksdag was reconstituted and made a two-chamber body, replacing the old Estates. Charles was an artist and a writer, his published works including *Fosterbröderne* (1848); *Hcidi, Gyllesdotter* (1852); *En Vikingsaga* (1855); and *Dikter*, a two-volume collection of poems (1863–1865).

CHARLES, Elizabeth (nee RUNDLE), English writer: b. Tavistock, England, Jan. 2, 1828; d. London, March 28, 1896. She married Andrew Paton Charles in 1851. Her books, based on semireligious themes, became very popular in England and the United States, the most famous of them being *The Chronicles of the Schönberg-Cotta Family* (1862), about Martin Luther. Among her other works are *The Martyrs of Spain and Liberators of Holland* (1862); *Diary of Mrs. Kitty Trevelyan* (1865); *Winifred Bertram and the World She Lived in* (1866); *The Draytons and Davenants* (1867); *Against the Stream* (1873); *The Bertram Family* (1876); and *Lapsed but Not Lost* (1877).

CHARLES, Jacques Alexandre César, French physicist, chemist, and inventor: b. Beaugency, France, Nov. 12, 1746; d. Paris, April 7, 1823. He taught physics at the Sorbonne and at the Conservatoire des Arts et Métiers, popularizing Benjamin Franklin's discoveries in electricity. In 1783 he made the first balloon using hydrogen gas, and himself made several ascents, including one to a height of 7,000 feet. Among his other inventions were a thermometric hydrometer and a number of optical instruments. He also anticipated the law of volumes named for Joseph-Louis Gay-Lussac (q.v.), and hence sometimes known as Charles's law. In 1785 he was elected to the Académie des Sciences.

CHARLES, Thomas, Welsh preacher: b. Llanfihangel Abercowin, Carmarthenshire, Wales, Oct. 14, 1755; d. Oct. 5, 1814. He was educated at Llanddowror and at Jesus College, Oxford, where he prepared for the Anglican ministry and received his B.A. degree in 1779. Ordained a deacon in 1778, he became a priest of the Church of England in 1780, and held several curacies. He soon became interested in Calvinistic Methodism, and because of his active work on its behalf was eventually denied employment by the Church of England. In 1784 he became a Methodist preacher and began a series of preaching journeys in Wales. Interested in the welfare of Welsh children, he established, in 1785, the sys-

tem of Welsh circulating schools, in which poor children were given instruction. Later, in 1789, he adopted the Sunday school system for those who worked during the week. He did much to kindle the great revivalist movement in Wales, establishing a press and organizing a movement for the wider distribution of Welsh Bibles, and in 1804 he helped to found the British and Foreign Bible Society. He issued a Biblical dictionary in four volumes (1805-1808) and some Welsh catechisms. Charles was in part responsible for the introduction of the circulating school system in Ireland and for the establishment of charity schools in Scotland, and the Gaelic School Society (1811). In 1810-1811 he organized the Welsh Calvinistic Methodists.

CHARLES, river, Massachusetts, flowing into Boston Bay between Boston proper and the former city of Charlestown. About 60 miles long, it rises in the southwestern part of Norfolk County and follows a winding course, first north, then east, northwest, and east again. The river is navigable to Watertown, 7 miles west of Boston.

CHARLES, Cape, cape, Virginia, situated opposite Cape Henry at the mouth of Chesapeake Bay, and forming the southern extremity of Northampton County, at latitude 37°7'N. and longitude 75°57'W. Near its tip is the town of Cape Charles, incorporated in 1886, and having a population (1950) of 2,427. Northeast of the cape, on Smith Island, is a lighthouse.

CHARLES ALBERT (Ital. CARLO ALBERTO), king of Sardinia: b. Turin, Italy, Oct. 2, 1798, d. Oporto, Portugal, July 28, 1849. The son of Charles Emmanuel, 6th prince of Savoy-Carignan (d. 1800), he was educated in France and Switzerland. For a short time after the abdication of Victor Emmanuel I in 1821, he served as regent of the kingdom, but was then exiled by the new king, Charles Felix, his distant cousin, and did not return to Piedmont until 1823. As the nearest heir, he succeeded to the throne on the death of Charles Felix in 1831. In the first years of his reign he promoted a number of beneficial reforms, but later became more absolute in his views. After the French Revolution of 1848, however, he granted a constitution which later became the basis for the Constitution of Italy, and he took the field against Austria on behalf of the revolted peoples of Lombardy and Venetia and the duchies of central Italy. The Austrians were defeated in several early encounters, but on July 23-25, 1848, Marshal Joseph Wenzel Radetzky won an overwhelming victory at Custoza, and Charles Albert was obliged to sue for an armistice. On its expiration he resumed hostilities, but the Battle of Novara, fought on March 23, 1849, proved fatal to his aspirations. On the same day he abdicated in favor of his son, Victor Emmanuel II, later king of Italy, and retired to Portugal.

CHARLES ALEXANDER. See **CHARLES**, prince of Lorraine.

CHARLES (I) ALEXANDER. See **CHARLES**, the name of two dukes of Württemberg.

CHARLES ANTHONY (Ger. KARL ANTON), prince of Hohenzollern-Sigmaringen: b.

Sept. 7, 1811; d. Sigmaringen, Germany, June 2, 1885. In 1849 he ceded his principality to King Frederick William IV of Prussia. As a general in the Prussian Army, he participated in a dispute over the reorganization of the army, from 1853 to 1862, and served (1863-1871) as military governor of the Rhineland region of Westphalia. The controversy over the candidature of his son Leopold for the crown of Spain in 1870 was the precipitating cause of the Franco-Prussian War.

CHARLES AUGUSTUS (Ger. KARL AUGUST), grand duke of Saxe-Weimar: b. Weimar, Germany, Sept. 3, 1757; d. Graditz, near Torgau, June 14, 1828. The son of Duke Ernest Augustus Constantine, he succeeded his father in 1758, his mother, Amalia, serving as regent for him until 1775. He served in the Prussian Army from 1786 until the Battle of Jena (1806), and then fought with the French until 1812. For his services as a member of the allied coalition against Napoleon (1813-1815), his duchy was made a grand duchy at the Congress of Vienna. Charles Augustus liberally patronized science and art, and under him his capital of Weimar became the literary center of Germany. He was a close friend of Johann Wolfgang von Goethe.

CHARLES CITY, city, Iowa, seat of Floyd County, situated at an altitude of 1,015 feet, on the Cedar River, 30 miles east-southeast of Mason City. It is served by the Illinois Central (freight only), the Chicago, Milwaukee, St. Paul and Pacific, and the Charles City Western railroads, and has an airport. The city serves as a trading center for the surrounding farming region, and has plant nurseries and establishments producing tractors, pharmaceuticals, and wood products.

The first permanent settlement was made in 1850 on a site originally known as The Ford. On incorporation, in 1869, the name of Charles City was adopted in honor of Charles Kelly, son of Joseph Kelly, the first settler. Government is by council and city manager; water supply system is municipally owned. Pop. (1950) 10,309.

CHARLES DE VALOIS, count of Valois, Anjou, and Maine: b. March 12, 1270; d. Nogent-le-Roi, France, Dec. 16, 1325. In 1285 he inherited from his father, King Philip III of France, the lordships of Crépy, La Ferté-Milon, Pierrefonds, and Béthisy, forming the countship of Valois. Five years later, by his marriage to Margaret, daughter of Charles II of Naples, he also became count of Anjou and of Maine. Charles aided Philip IV of France against England and in Flanders, and assisted his father-in-law in the latter's war with Aragon. Having married, as his second wife, Catherine of Courtenay, granddaughter of Baldwin II, Latin emperor of Constantinople, Charles claimed the throne of Constantinople, but was dissuaded from this ambition by Pope Boniface VIII. He was equally unsuccessful in his candidature for the imperial throne, Henry of Luxembourg being chosen emperor, as Henry VII, in 1308. During the reign of Louis X of France (1314-1316), Charles was a leader of the reactionary feudal group. His eldest son became king of France as Philip VI, thus founding the French royal house of Valois.

CHARLES D'ORLEANS. See **ORLÉANS**, **CHARLES**, DUKE OF.

CHARLES EDWARD. See **STUART, CHARLES EDWARD LOUIS PHILIP CASIMIR.**

CHARLES EMMANUEL I (Ital. **CARLO EMANUELE**), duke of Savoy: b. Rivoli, Italy, Jan. 12, 1562; d. Savigliano, July 26, 1630. On the death of his father, Emmanuel Philibert, in 1580, he succeeded to the duchy. Five years later he married Catherine, daughter of Philip II of Spain. With the aid of his father-in-law, he formed the plan of adding Provence to his dominions, and in 1589 the Parlement of Aix acknowledged him as protector of the province. By 1601, however, the French had forced him to relinquish all territory beyond the Rhone River. Charles Emmanuel was no more successful in his plans to conquer Cyprus and Macedonia, and in 1602 the Swiss repulsed an unprovoked Savoyard attack on Geneva. At various times the duke was at war with France, Spain, and Tuscany, but in 1618 he was obliged to make peace with all his enemies. Ten years later he joined Spain in a war against France. Unaided by his ally, he was able to defend his territory only with great difficulty, and he died when the struggle had almost exhausted his army's strength.

CHARLES EMMANUEL II, duke of Savoy: b. June 20, 1634; d. June 12, 1675. On the death of his father, Victor Amadeus I, in 1638, he succeeded to the duchy, his mother, Christina, sister of Louis XIII of France, serving as regent until her death in 1663. During the regency two of the young king's uncles fomented rebellions against him, but there was less dissension after he assumed control of the government. His reign saw considerable artistic development.

CHARLES EMMANUEL III, duke of Savoy and, as **CHARLES EMMANUEL I**, king of Sardinia: b. Turin, Italy, April 27, 1701; d. there, Feb. 20, 1773. The son of Victor Amadeus II of Savoy (Victor Amadeus I of Sardinia), he succeeded his father as duke of Savoy and king of Sardinia on the latter's abdication in 1730. As an ally of France and Spain, he joined in the War of the Polish Succession, but gained no advantage from the Treaty of Vienna (1735). In the War of the Austrian Succession he was an ally of Austria, and by the Treaty of Aix-la-Chapelle (1748) acquired part of the Duchy of Milan. During his reign Piedmont enjoyed much prosperity.

CHARLES EMMANUEL IV, duke of Savoy and, as **CHARLES EMMANUEL II**, king of Sardinia: b. Turin, Italy, May 24, 1751; d. Rome, Oct. 6, 1819. In 1796, on the death of his father, Victor Amadeus III of Savoy (Victor Amadeus II of Sardinia), he became duke of Savoy and king of Sardinia. Two years later, however, the French seized Savoy and Piedmont, and he retained only Sardinia. He abdicated in favor of his brother, Victor Emmanuel I, in 1802. Four years before his death he became a Jesuit.

CHARLES (II) EUGENE. See **CHARLES**, the name of two dukes of Württemberg.

CHARLES FELIX (Ital. **CARLO FELICE**), king of Sardinia: b. Turin, Italy, April 6, 1765; d. April 27, 1831. The son of Victor Amadeus III, duke of Savoy (Victor Amadeus II of Sardinia), he served as viceroy of Sardinia from

1799 to 1806, and from 1817 to 1821. In that year, following the abdication of his brother, Victor Emmanuel I, he succeeded to the throne of Sardinia while absent from Turin. Returning to the city, he exiled his distant cousin, Charles Albert, who had been serving as regent and had granted a constitution, and defeated the constitutional forces. The last ruler of the main line of the house of Savoy, he was succeeded by Charles Albert, of the branch of Savoy-Carignan.

CHARLES FRANCIS JOSEPH. See **CHARLES I**, emperor of Austria.

CHARLES X GUSTAVUS, king of Sweden: b. Nyköping, Sweden, Nov. 8, 1622; d. Göteborg, Feb. 13, 1660. The grandson of King Charles IX and the nephew of Gustavus Adolphus, he received part of his excellent education from Count Axel Gustafsson Oxenstierna, regent during the minority of Queen Christina, and spent the years 1638–1640 in Germany, the Netherlands, and France. When Christina abdicated, in 1654, he succeeded to the throne and in the following year declared war on Poland. Invading the country in 1656, his troops won the Battle of Warsaw, but Denmark, the empire, and Russia declared war on Sweden, and he was forced out of Poland in 1657. He successfully invaded Denmark (1658), however, and in 1660, shortly after the king's death, Denmark ceded to Sweden the remaining provinces she held in the southern and southwestern part of the Swedish mainland, thus restoring to Sweden her natural frontiers. In addition, Livonia was ceded to Sweden by Poland.

CHARLES XIV JOHN (original name: **JEAN BAPTISTE JULES BERNADOTTE**), king of Sweden and Norway: b. Pau, France, Jan. 26, 1763; d. Stockholm, Sweden, March 8, 1844. The son of Henri Bernadotte (1711–1780), a lawyer of Pau, he enlisted in a French regiment of marines in 1780. Although he was only a sergeant by 1789, he rose rapidly thereafter, becoming a colonel in 1792 and a general of division two years later. He served with distinction in the campaigns on the Rhine, and in 1797 first met Napoleon Bonaparte, who formed a high opinion of Bernadotte's abilities. In the following year he married Desirée Clary (1777–1860), sister-in-law of Joseph Bonaparte, and he served briefly as minister of war in 1798. On the establishment of the empire in 1804, Bernadotte was created marshal of France, and, after the Battle of Austerlitz, prince of Pontecorvo. In the Battle of Wagram (1809), he led the Saxon contingent. At this time, Gustaf IV had been deposed as king of Sweden. He was succeeded by his uncle, Charles XIII, who, having no children, had adopted as his successor Charles August (known also as Christian), prince of Schleswig-Holstein-Sønderborg-Augustenburg. The latter died in 1810, however, and in August of that year succession to the Swedish crown was offered to Marshal Bernadotte. After obtaining the consent of Napoleon, he accepted, and in October he arrived in Sweden, where, having previously adopted the Lutheran faith, he was proclaimed heir apparent to the throne under the title of Prince Charles John. He had not long been established in this dignity before serious disagreements arose between him and Napoleon, whose blockade of the Continental ports was detrimental to Swedish commercial interests.

The final result was a complete rupture of relations, and in 1813 Sweden joined the allied coalition against Napoleon. At the Battle of Leipzig (1813), Charles John contributed effectively to the allied victory. The acquisition of Norway was one of his chief aims; it was provisionally ceded by Denmark under the Treaty of Kiel (1814), but a military campaign was required to make the cession effective. In 1818, following the death of Charles XIII, Charles John became king of Sweden and Norway. During his reign agriculture and commerce made substantial advances, and many important public works were completed. Although the king could not speak Swedish and was criticized for his ultraconservatism, he was generally popular with his subjects.

Consult Barton, D. P., *The Amazing Career of Bernadotte, 1763-1844* (Boston 1929); Scott, F. D., *Bernadotte and the Fall of Napoleon* (Cambridge, Mass., 1935).

CHARLES LEOPOLD. See CHARLES V, duke of Lorraine.

CHARLES LOUIS (Ger. KARL LUDWIG), DUKE OF TESCHEN, archduke of Austria: b. Florence, Italy, Sept. 5, 1771; d. Vienna, Austria, April 30, 1847. The third son of Emperor Leopold II, he spent his youth in Tuscany (of which his father was then grand duke), Vienna, and the Austrian Netherlands. Adopting a military career, he distinguished himself at the Battle of Jemappes (1792), and two years later was made a major general. He commanded the advance guard of Friedrich Josias, prince of Saxe-Coburg, at Neerwinden in 1793 and was then appointed governor general of the Austrian Netherlands. In 1796 he became field marshal of the empire and commander of the Austrian forces on the Rhine. After turning his retreat at Wetzlar into a victory over Gen. (later Comte) Jean Baptiste Jourdan, he obtained victories at Amberg and Würzburg, compelling Gen. Jean Victor Moreau to retreat. In the winter of 1797, Charles Louis captured Kehl, the only position the French occupied in Germany, and was appointed governor and captain general of Bohemia. After the fruitless Congress of Rastatt, he became head of the forces on the Rhine and, in 1799, defeated Jourdan at Stockach. Misunderstandings between him and the Russian general, Count Aleksandr Vasilievich Suvorov, and poor health then forced him to resign his command and retire to Bohemia. In 1809, Charles Louis won a victory over Napoleon at Aspern, but he was defeated at Wagram and retired from the army. He was the author of several excellent books on the theory and art of war.

CHARLES LOUIS (Ger. KARL LUDWIG), archduke of Austria: b. Vienna, Austria, July 30, 1833; d. there, May 19, 1896. The younger brother of Emperor Francis Joseph of Austria and of Emperor Maximilian of Mexico, he served as governor of the Tirol from 1855 to 1861. He was the father of Archduke Francis Ferdinand, whose assassination at Sarajevo in 1914 was the immediate cause of World War I.

CHARLES MARTEL (Ger. KARL MARTELL), Frankish ruler of Austrasia: b. ?689; d. Quierzy, France, Oct. 22, 741. The natural son of Pepin of Herstal, mayor of the palace under the last Merovingian kings, he was imprisoned

after the death of his father (714), but escaped and by 715 was recognized as ruler of Austrasia. By 717 he had conquered the Neustrians and made himself mayor of the palace. Through his unification of the Franks he saved France from conquest by the Arabs, who had crossed the Pyrenees in 719. Near Poitiers, on Oct. 25, 732, he won a decisive victory over the forces of Abd-er-Rahman, Arab emir of Spain. He also extended his influence over the various tribes of western Germany and, in 735, over Burgundy. Charles Martel was a man of foresight and ability, resembling in many respects his celebrated grandson, Charlemagne.

CHARLES TOWN, town, West Virginia, seat of Jefferson County; altitude 530 feet; 8 miles southwest of Harper's Ferry; on the Baltimore and Ohio and the Norfolk and Western railroads. It is the center of an agricultural region with deposits of limestone and dolomite. Brassware, fertilizers, refrigeration and wood products are manufactured. Charles Town was named for Charles Washington (brother of George) who laid it out in 1786. It was first incorporated in 1787. Here John Brown, after his raid at Harper's Ferry, was tried and hanged in 1859. On Oct. 18, 1863, a Confederate cavalry division, under Gen. John Daniel Imboden (1823-1895), captured the place and took prisoners and large quantities of military stores but, on the approach of a superior Union force, immediately withdrew. Pop. (1940) 2,926; (1950) 3,030.

CHARLESTON, city, Illinois, and seat of Coles County; altitude 686 feet; on the New York Central, and the Nickel Plate (New York, Chicago and St. Louis) railroads; 135 miles northeast of St. Louis; with an airport. The city is situated in an agricultural and dairy farming area. The principal industries include railroad shops, flour mills, metal manufactures, and shoe, broom, woolen, and cheese factories. Charleston is the site of the Eastern Illinois State College established in 1899. In and near the city are many mementos of Abraham Lincoln and his parents, including the original log cabin, seven miles south of the city. One of the Lincoln-Douglas debates in 1858 was held here. Government is by mayor and council. Pop. (1930) 8,012; (1940) 8,197; (1950) 9,146.

CHARLESTON, city, Missouri, seat of Mississippi County, altitude 326 feet, 15 miles by road from Cairo, Ill. and on the Missouri Pacific Railroad. Big Oak State Park is nearby, and there are many Indian mounds in the vicinity, of archaeological interest. Charleston distributes cotton, grain, potatoes, fruit, livestock, and soy beans; has flour mills, cotton gins and compresses and woodworking shops; and manufactures shoes. The city is governed by council and manager. Pop. (1940) 5,182; (1950) 5,500.

CHARLESTON, city, South Carolina, is the largest city in the state, Charleston County seat, and an important Atlantic seaport, located on the southeast coast of South Carolina, practically midway between New York, N. Y. and Miami, Fla. With a land area of 4.49 square miles and an altitude ranging from sea level to 17 feet, the city is situated on a narrow peninsula between the Cooper and Ashley rivers, at the head of a broad, virtually landlocked bay formed by their confluence, $7\frac{1}{2}$ miles from the Atlantic Ocean. By automobile, Charleston is 414 miles southwest of Richmond, Va.; 109 miles northeast of Savannah, Ga.; and 114 miles southeast of Columbia, S. C. The city enjoys a rather mild, equable climate, with a mean average temperature of about 66°F.; the average annual rainfall of around 45 inches is distributed somewhat unevenly throughout the year.

Charleston is a city of unusual historic and scenic interest. The older, residential section stretches from Broad Street south to the lower end of the peninsula, where the Battery (White Point Gardens) commands a view of the harbor. To the north, on the neck of the peninsula, is

the industrial area with its phosphate plants and oil refineries. Along the Ashley River, Hampton Park occupies part of the site of the South Carolina Interstate and West Indian Exposition (1901-1902). Southeast, over the Cooper River Bridge, about 15 minutes from the city, are popular ocean beach resorts on the Isle of Palms and Sullivan's Island with several beautiful and gracious hotels; while to the southwest is Folly Beach, reached by way of the Ashley River Memorial Bridge. Within a radius of 30 miles of Charleston are a number of famous plantation gardens, which attract thousands of tourists each spring. Particularly noteworthy are Magnolia, Runnymede, Middleton Place and Mateeba Gardens on the Ashley River; Cypress Gardens on the Cooper River; and the Oaks on Goose Creek.

The entrance to Charleston's excellent harbor has been improved by the construction of two converging stone jetties, and by increasing the depth of the channel to 35 feet. Flanking the entrance to the harbor are historic Fort Moultrie on Sullivan's Island and Fort Johnson on James Island, while Fort Sumter and Castle Pinckney are situated on small islands in the bay. Becoming the official state port in 1924, Charleston has a nine-mile waterfront, principally on the Cooper River, where numerous docking and warehouse facilities are provided. About five miles north, also on the west bank of the Cooper, is the only first-class United States Naval Base on the Atlantic coast south of Norfolk, Va.; two and a half miles beyond are the port terminals, formerly an army supply base.

Transportation.—On several modern highways and inland waterways, Charleston is served by the Eastern, National, and Delta airlines, by the Atlantic Coast Line, Seaboard Air Line, and Southern railroads; by motor bus and truck lines, and by various steamship lines operating on the coastwise, intracoastal, and overseas routes. The city has a well-equipped municipal airport and yacht basin.

Commerce and Industry.—Charleston has considerable manufacturing and shipping, an extensive wholesale and retail trade, and an important tourist business. Leading products of its trade include lumber, truck garden produce, and sea foods; while its principal manufactures comprise fertilizer, wood products, asbestos, asphalt, paper, petroleum products, shipbuilding, turpentine, cigars, and textile products. The chief exports include lumber, petroleum products, cotton and cotton goods, and tobacco; imports consist principally of petroleum, raw materials for the manufacture of fertilizer, and sugar.

Government.—The mayor and council are each elected for a term of four years, half of the council being elected by wards, and half at large. The administrative officials and boards that head the various departments into which the municipal government is organized are partly appointive by the mayor and partly elective by the council. The city has made considerable progress in slum clearance and low-rent government housing. The United States government maintains at Charleston a federal district court, headquarters of the customs district of South Carolina, the 6th Naval District, the 6th Light-house District, and the South Atlantic Division of the Army Engineer Corps. Fort Moultrie is the headquarters of the harbor defense of Charleston.

Education.—Among the many educational

institutions in Charleston are the College of Charleston, founded in 1770, chartered in 1785, a municipal college since 1837, and one of the oldest free city colleges in the United States; the Medical College of South Carolina, established in 1823, and a state institution since 1913; the Citadel (Military College of South Carolina), founded in 1842, originally an arsenal; Porter Military Academy (1867), for boys; and Ashley Hall, a girl's school. The Charleston Library Society, a private enterprise organized in 1748, is the third oldest library in the United States; this society founded the Charleston Museum in 1773. In addition, there is the Charleston County Free Library, established in 1930.

Culture.—Charleston has enjoyed a distinguished cultural history, and many of the traditions of the old South still survive today. The first building in the United States designed wholly for theatrical purposes was the Dock Street Theater, which opened on Feb. 12, 1736, with Farquhar's *The Recruiting Officer*. Faithfully restored with WPA assistance, it was reopened in 1937 with a presentation of the same play. The Saint Cecilia Society, founded in 1766, was America's pioneer musical organization, and sponsored the nation's first symphony orchestra; later it became a purely social group. In the field of painting, such noted artists as Washington Allston, Samuel F. B. Morse, John James Audubon, Thomas Sully, John Blake White, and Charles Fraser lived in Charleston during the early 19th century. Shortly before the Civil War, Charleston was the center of an important literary group associated with *Russell's Magazine* (1857-1860), which included William Gilmore Simms, Henry Timrod, Paul Hamilton Hayne, William John Grayson, and Samuel Henry Dickson. After World War I, there was a literary revival in Charleston led by Dubose Heyward and Hervey Allen: together they founded the Poetry Society of South Carolina in 1920, and wrote *Carolina Chansons: Legends of the Low Country* (1922).

Buildings.—The older section of the city still retains much of its 18th century aspect, and legislation has been passed to preserve its unique character. Notable public buildings include the Old Powder Magazine (1713); County Court House (1792); City Hall (1801); Records (Fireproof) Building (1822), designed by Robert Mills, and believed to be the first fireproof construction in the United States; and Market Hall (1841), now a Confederate museum. Three of the city's most important churches are St. Michael's Episcopal Church (1752-1761); St. Philip's Episcopal Church (1835-1838), in whose cemetery are buried many distinguished South Carolinians; and the French Huguenot Church (1845). Domestic architecture is represented by excellent examples from the various early periods: the Georgian colonial style (Heyward-Washington House, 1740-1750; Robert Brewton House, c. 1730; Miles Brewton, or Pringle House, c. 1765; Col. John Stuart House, c. 1772); the postcolonial style of the early republican period (Joseph Manigault House, 1790 or later; Nathaniel Russell House, c. 1811); and the more grandiose neoclassicism of the antebellum period (Allston House, c. 1850). Characteristic of Charleston is the so-called single house, set with the narrow gable end toward the street, and the entire long side hung with open galleries, two or three tiers in height.

History.—In April 1670 three ships, carrying some 150 English and Irish colonists under the leadership of Governor William Sayle, landed on the west bank of the Ashley River to make the first permanent settlement in the Province of Carolina. Known as Albemarle Point until 1671, when it was renamed Charles Town in honor of King Charles II, this location proved poorly adapted for defense, and in 1672 a walled town was laid out about six miles distant at Oyster Point, the present site of Charleston, to which the colonists moved in 1680. The new settlement, which subsequently became known as Charles Town, soon developed a substantial Indian and maritime trade. Rice, first cultivated in 1685, was the province's staple crop until the second half of the 18th century, when the introduction of indigo further strengthened the planter class and the system of slave labor. In 1706, during Queen Anne's War, a French-Spanish fleet attempted unsuccessfully to take the town, and in 1718 a campaign to end piracy along the Carolina coast resulted in the capture of Stede Bonnet, Blackbeard, and Richard Worley. By 1775, Charleston had become the third most important seaport in the American colonies and the largest and most prosperous city south of Philadelphia. It was the first Southern city to join the revolutionary movement, Fort Johnson being seized on Sept. 15, 1775, and the royal governor forced to flee. The Provincial Congress of South Carolina adopted the first independent state constitution of the American colonies on March 26, 1776, Charles Town remaining the state capital until 1786, when Columbia was founded for that purpose. Charles Town was repeatedly attacked by the British and finally surrendered on May 12, 1780, after a two month's siege by land and sea. The British evacuated the city on Dec. 14, 1782.

Charleston was incorporated as a city under its present name on Aug. 13, 1783. The Non-intercourse and Embargo acts and the War of 1812 dealt a heavy blow to its commerce, but the introduction of cotton growing on a large scale after 1800 soon became a major factor in the city's continuing progress. With the completion of the South Carolina Railroad (from Charleston to Hamburg, S. C., on the Savannah River; 136 miles, then the longest passenger steam railroad in the world), considerable amounts of Up Country produce were diverted from the rival port of Savannah. Charleston was the scene of the passing of the Ordinance of Nullification (Nov. 24, 1832), and the first Ordinance of Secession (Dec. 20, 1860). The Civil War began with the bombardment and capture of Fort Sumter by Confederate troops on April 12/13, 1861. Into Charleston harbor came the first fleet of Federal ironclads (April 7, 1863) and the first submarine, the Confederate *Hunley*, to sink an enemy ship in time of war (Feb. 17, 1864). The city held out until Feb. 17, 1865, when after a siege lasting 567 days it was finally evacuated.

With the overthrow of carpetbag rule after 1876 by Governor Wade Hampton, Charleston gradually began to recover from the setback of the Reconstruction period, and since World War I its commerce and industry have greatly expanded. On Aug. 31, 1886, about 90 per cent of the city's buildings were damaged by a severe earthquake, which destroyed between \$5,000,000 and \$6,000,000 worth of property; the city was

struck by two tornados on Sept. 20, 1938, and by a hurricane on Aug. 12, 1940.

Population.—The first colonists were soon followed by English settlers from Barbados and Virginia, French Huguenots, New England dissenters, Dutch immigrants, and Quakers; Scotch-Irish Presbyterians, Swiss and South German Lutherans, French Catholics from Acadia, Welsh from Delaware, and Jews arrived in the 18th century; and North Germans and Irish in the 19th century. The first Negro slaves were brought in 1672, and Negroes now compose 46 per cent of the city's population. Population: (1685) c. 2,500; (1700) c. 5,000; (1775) 15,000; (1800) 18,824; (1850) 42,985; (1900) 55,807; (1940) 71,275; (1950) 68,243.

Bibliography.—Leiding, H., *Charleston, Historic and Romantic* (Philadelphia 1931); Wallace, David D., *History of South Carolina* (Chicago 1934); Bowes, F. P., *Culture of Early Charleston* (Chapel Hill 1942); Molloy, R., *Charleston, A Gracious Heritage* (New York 1947).

CHARLESTON, city, West Virginia, is the capital and the second largest city in the state, and the seat of Kanawha County. It is situated at an altitude of about 600 feet in the Kanawha Valley, on the navigable Kanawha River at its confluence with the Elk. The river flows through the heart of the city, dividing it into north and south sections which are connected by bridges. Charleston is partly hemmed in by the western foothills of the Allegheny Mountains. It is located 50 miles east of Huntington, 212 miles southeast of Cincinnati, and 387 miles southwest of Washington, D.C. The city is on a network of modern highways and is served by motorbus and truck lines in all directions, by river boats, and also by the Baltimore and Ohio, the New York Central, the Chesapeake and Ohio, and the Virginian railroads. A mile north of the city is the \$9,000,000 county-owned Kanawha Airport. This airport serves as a terminal for several major airlines, and is also the home base of a West Virginia National Air Guard squadron.

Charleston is not only the political center of the state but also its foremost industrial and commercial center. It is the hub of a district, rich in natural resources, which produces large quantities of bituminous coal, oil, natural gas, and brine. Manufactures in the city and its immediate vicinity include base chemicals, glass and glass products, axes, machinery, tools, mining equipment, and wood and clay products. Some of its factories are among the largest of their kind in the world. In the manufacture of chlorine, the local brines are used extensively. The city is also an important distributing center for the wholesale and retail trades.

Charleston is governed under the mayor-council plan. After 1936 the city spent large sums for public improvements, including a 5-lane river front boulevard, bridges, schools, and a city auditorium, which seats 3,600 persons. Its educational and cultural institutions embrace a modern public school system, parochial and commercial schools, Morris Harvey College, Mason College of Music and Fine Arts, the Kanawha County Public Library, the state libraries, the state museum, the Open Forum; the Civic Music Association, which sponsors each season concerts by noted artists; the Charleston Symphony Orchestra, and a Little Theater movement. The city has several parks, playgrounds, and recreation centers, and nearby are a number of points of scenic interest. Centered in Charleston are

most of the functions of the state government, and the United States government maintains a district court and other agencies there. Among the city's many attractive, modern buildings, the most outstanding is the state capitol, a U-shaped limestone and marble structure of Italian Renaissance design, which replaced the old capitol destroyed by fire in 1921. It was completed in 1932. Two additional buildings to house state departments were opened in 1951.

History.—In 1787 Col. George Clendenin, a member of the Virginia Assembly from Greenbrier County, was delegated by Governor Edmund Randolph to organize a company of rangers for the protection of the people residing in the Great Kanawha Valley, and in 1788 Colonel Clendenin erected a fort which he called Fort Lee after Governor Henry Lee of Virginia, on the site of the present city of Charleston. The completion of this fort marked the beginning of the city. Scotch-Irish and German settlers left the Shenandoah Valley to settle here. In 1789 Kanawha County was organized and Fort Lee became in effect the county seat. The Virginia Assembly authorized the establishment of a town on the site in 1794. At first the community was called Charles Town; later the name was shortened to Charleston. For about a century the growth of the town was very slow. In 1870, when its population was about 3,000, Charleston was incorporated as a city, and in the same year was made the state capital, but lost this distinction to Wheeling in 1875. However, in 1885 Charleston became the permanent capital. With large-scale industrial development of the Kanawha Valley since the turn of century, and especially since World War I, the city's progress has been rapid. Pop. (1900) 11,099; (1950) 72,878.

CHARLESTOWN, town, Indiana, in Clark County. It is 14 miles by highway northeast of Louisville, Ky. and is on the Baltimore and Ohio and the Pennsylvania railroads. The town is situated in a rich agricultural district producing tobacco, livestock and dairy products, as well as limestone from quarries. It is the site of the Indiana Ordnance Works and the Hoosier Ordnance Plant. Pop. (1950) 4,760.

CHARLESTOWN, former city, Massachusetts, since 1874 a part of the municipality of Boston. One of the chief navy yards in the United States, occupying an area of about 100 acres, is in the southeast part of Charlestown. It was settled as early as 1629, and in 1634 became a town, its original territory being considerably larger than at present, having been divided up to form the towns of Woburn, Malden, Stoneham, Burlington and Somerville, and parts of Medford, Cambridge, Arlington and Reading. The Battle of Bunker Hill (q.v.) was fought here June 17, 1775, at which time the British set fire to the town, destroying 320 buildings. It had a population of 25,655 at the time of its annexation to Boston.

Consult Frothingham, Richard, *History of Charlestown* (Boston 1845-1849); Sawyer, Timothy T., *Old Charlestown* (Boston 1902).

CHARLEVILLE, shâr'lê-vêl', commune, France, in the Department of the Ardennes, on the east bank of the Meuse, opposite Mézières, with which it is connected by a suspension bridge. It is regularly built, has straight, wide streets, and a wide public square. It manufactures hard-

ware, leather, sugar, brushes, and beer; and the Meuse affords facilities for considerable trade in metals, coal, iron, slate, wire, and nails. It was the medieval Arcae Remorum and Carolopolis, and an important military station until the fortifications were destroyed in 1687. Pop. (1946) 20,193.

CHARLEVOIX, shär'lë-vwà', **Pierre François Xavier de**, French Jesuit traveler: b. St. Quentin, Oct. 29, 1682; d. La Flèche, Feb. 1, 1761. He became a member of the Society of Jesus in 1698 and taught in Quebec from 1705 to 1709. After a brief return to France he was again sent to America in 1720 by the duke of Orléans. The object of this journey was the discovery of the "Western Sea" then supposed to be west of the Mississippi. He voyaged down the Mississippi to New Orleans. His chief title to fame rests on his *Histoire et description générale de la Nouvelle France* (1744; Eng. trans. by J. G. Shea, 1866-1872). His other works include *Histoire de l'établissement, des progrès et de la décadence du Christianisme dans l'empire du Japon* (1715); *Vie de la mère Marie de l'Incarnation* (1724); *Histoire de l'Isle Espagnole, ou de Saint-Dominique* (1730); and *Histoire du Paraguay* (1756).

CHARLEVOIX, shär'lë-voi, city, Michigan, summer resort, and Charlevoix County seat; altitude 592 feet; at the mouth of the Pine River, fronting on Lake Michigan, Lake Charlevoix, and Round Lake, 41 miles north-northeast of Traverse City, on the Pere Marquette Railroad. Corn, radish seed, and potatoes are the main crops. There are whitefish and trout fisheries, and a branch station of a United States fish hatchery is here. The early settlement, on the site of an Indian village, was known as Pine River. The city was chartered in 1905. Pop. (1950) 2,695.

CHARLOTTE, shär'löt', city, Michigan, and seat of Eaton County, altitude 907 feet, 18 miles southwest of Lansing, on Battle Creek River, and on the Michigan Central and Grand Trunk railroads, one federal and three state highways. It is in a dairying and bean-raising region. Livestock is auctioned here. The manufactured products are chairs, radios, road machinery, sauerkraut, ice cream and condensed milk, and canned vegetables. Charlotte was settled in 1835, incorporated in 1871 as a village, and as a city in 1891. It has a mayor and council. Pop. (1940) 5,544; (1950) 6,606.

CHARLOTTE, principal city, North Carolina, and seat of Mecklenburg County, altitude 732 feet, on the Southern, Seaboard Air Line, Norfolk Southern, and Piedmont and Northern railroads, 300 miles southwest of Richmond and 231 miles northeast of Atlanta, and in south central North Carolina, 20 miles from South Carolina border. It is the point of convergence of three federal highways and three state highways. There are one major municipal airport and three privately-owned airports. The city covers an area of 30 square miles in the approximate center of Mecklenburg County.

Charlotte is the retail marketing center for an area comprising 24 surrounding counties in both North and South Carolina. The population of these counties approaches 1,250,000. The 1948

census of business published by the Bureau of the Census listed the city's retail sales as \$168,818,000 and wholesale sales as \$962,651,000.

Educational institutions include 30 public schools, having a combined enrollment of 21,000; Queens College (Presbyterian, founded 1857) for women; Charlotte College (coeducational, junior college); Johnson C. Smith University (formerly Biddle University, founded 1867) for Negroes; Davidson College (Presbyterian, located 20 miles north in Davidson, N. C.) for men. The city also has a well-equipped public library, supported by city and county tax levies.

Charlotte is located in the center of the vast Southern textile industry which is the predominating industry of the region. There are over 400 manufacturing plants in Mecklenburg County; 53 manufacturing textile products; 89 in the food industry; 30 making wearing apparel; 54 publishers, printers and bookbinders; 33 chemical manufacturers; 36 machinery manufacturers; and other miscellaneous industries. In 1950, manufacturing employment in the county exceeded 18,500.

The city is also an important construction and banking center for the Carolinas. The headquarters of many of the largest construction firms of the South are located here and there is a branch of the Federal Reserve Bank.

Charlotte has a city manager government with a mayor and 7 councilmen. Modern zoning regulations are in force. The waterworks is owned and operated by the municipality.

History.—Charlotte was settled about 1750, was incorporated in 1768, and became the county seat in 1774. It received its city charter in 1866 and its second charter in 1907. President Andrew Jackson and President James K. Polk were born near Charlotte. The Mecklenburg Declaration of Independence, signed in the city in May, 1775, is commemorated by a monument at the County Court House. In September, 1780, Lord Cornwallis entered Charlotte, and occupied it for several days. He called it a "hornet's nest," and this has since been adopted as the city's emblem. Later in the year Gen. Horatio Gates made his headquarters here. The city on April 10, 1865 was the last meeting place (at the Phifer Home) of the full Confederate Cabinet. In the early 1800's gold was produced in Mecklenburg and Cabarrus counties, and in 1837 a branch United States mint was established at Charlotte. This branch mint was torn down in 1935 to make way for a new wing of the post office. However, a group of interested citizens obtained the materials and reconstructed the building on another site. It is now the Mint Museum of Art. Pop. (1920) 46,338; (1930) 82,675; (1940) 100,899; (1950) 134,042.

CHARLOTTE AMALIE, shär'löt ä-mäl'yë, formerly (1921-1937) St. Thomas, seaport and capital of the Virgin Islands (q.v.). Pop. (1940) 9,801; (1950) 11,463.

CHARLOTTENBURG, shär'löt'n-bürg, residential section of Berlin, Germany, now in the British Sector, five miles west of the center of Berlin, and served by the Stadtbahn, the Ringbahn, and the elevated and underground railways. Once a city of Brandenburg, Prussia, it was an important industrial center, noted especially for its porcelain factory, established in 1761. It still manufactures porcelain along with such items as

beer, glass, pottery, and dyes, although its chief significance is as a residential district.

It is an important educational and cultural part of Berlin, containing a technical academy with a valuable architectural museum, state schools of music and of plastic and graphic arts, a physical-technical institute, a zoological garden, and several museums. Buildings of interest include the Charlottenburg palace, originally a country house erected by Sophie Charlotte, wife of Frederick I, and its garden with the famous mausoleum, erected in 1810 by Friedrich von Gertz, containing the tombs of Frederick William III and his queen, Louise, and those of emperor William I and Empress Augusta.

History.—First called Lietzenburg, after the castle erected by Sophie Charlotte in 1695–1699, the town was issued a charter in 1715. The castle was the favorite of a long line of rulers, and was later renamed in honor of its builder. The town's growth expanded rapidly in the beginning of the 20th century and in 1920 Charlottenburg was incorporated into Greater Berlin (Stadt Berlin). The entire district suffered severe damage from air raids and hand to hand fighting during World War II. Pop. (1946) 208,453.

CHARLOTTESVILLE, city, Virginia, seat of Albemarle County, at an altitude of 500 feet, 70 miles west of Richmond, on the Southern and Chesapeake and Ohio railroads and state and federal highways. It lies in a rich agricultural, apple and cattle raising section, famous as the home of Albemarle pippin apples. Industries include woolen and silk mills, underwear, shirt, dress, and drapery factories, and a law book publishing house. The University of Virginia, founded (1819) and planned by Thomas Jefferson and Monticello, Jefferson's home, are located in or near the city. The site of Charlottesville was settled about 1737 and named in 1762 for George III's queen. It became a town in 1851 and a city in 1888. It is governed by a city manager and council. Pop. (1950) 25,969.

CHARLOTTETOWN, city, Prince Edward Island, Canada, capital of the province situated on a commodious harbor formed by the confluence of three navigable rivers on the southern shore of the island (Northumberland Strait). It was founded by the French as Port La Joie in 1750, but was renamed after the British conquest from the consort of King George III. Charlottetown is the industrial, commercial, and educational as well as political center of this the smallest of the Canadian provinces. Its industries, of a miscellaneous character, employ about 600 persons and have an output of \$7 million, including the workshops of the Prince Edward Island Railway and of the airport. In addition to four grade schools and two business colleges, the educational institutions include the provincially supported Prince of Wales College and St. Dunstan's College (Roman Catholic). Charlottetown has several large churches, two hospitals, a provincial sanatorium, and the Falconwood (provincial) Mental Hospital. In the attractive legislative buildings of the province is a plaque which commemorates the holding here in 1864 of the first conference of political leaders to discuss the project of the confederation of the British American colonies into the Dominion of Canada. Pop. (1951) 15,887.

CHARLTON, John, Canadian statesman: b. near Caledonia, N. Y., Feb. 3, 1829; d. Lynedoch, Ontario, Feb. 11, 1910. He was educated at the Springville Academy, went to Ontario in 1849. He was for some years a farmer and merchant, and acquired a fortune in the lumber business. In 1872 he was elected to the House of Commons as a Liberal. He attracted attention through his knowledge of trade and tariff questions and advocated government intervention in private and public morality. He supported the Conservative premier during the crisis of the Kiel Rebellion in 1885. He secured the passage of various laws for the protection of women and girls and was an advocate of reciprocity with the United States.

He wrote a volume of *Speeches and Addresses* which was published in Toronto in 1905.

CHARM, anything believed to possess some occult or supernatural power, such as an amulet, spell, potion, or precious stone, but properly applied to spells couched in formulas of words or verse.

Among celebrated charms the Danish Hane brog, or national banner, stands prominent. This banner was said to have been woven in a day and a night by three daughters of a celebrated Norse chieftain, of the race of Ynglings said to be descended from the god Odin. These girls were deeply versed in the lore of the gods, giants, dwarfs and norns, and in the centre of the banner they placed a raven, the bird of Odin, wonderfully lifelike and realistic. The superstition was that the result of a battle was foretold by this raven, which if victory was to fall to the possessors of the banner, held its head and bill in an upright position. By observing this banner the Danes in three years' time had won 27 important battles, going into action only when the raven looked skyward. If the bird looked droopy and held its head low, they remained in camp, or, if in action, and the attitude of the raven suddenly changed, they withdrew from the field. Alfred the king of the English Saxons, noting the enthusiasm which this banner inspired in the Danes determined to capture it, and succeeded after a savage battle in which the Danes fought desperately for three hours. When, however, it fell into the hands of the Saxons, and the head and wings of the raven drooped, there was a general rout. The Danes were models of courage and bravery so long as superstition fanned the fire of faith in their hearts, but they were arrant cowards the minute they realized that their idol was powerless to protect them. Another curious charm is to be seen in the National Museum at Washington. This is a necklace of human fingers which was captured from the Sioux Indians in 1876, the loss of which brought about the subjection of the Indians.

The word charm is also used to denote attractive personal or physical characteristics.

CHARMES, shârm, Francis, French editor: b. Aurillac, Cantal, April 21, 1848; d. Paris, Jan. 4, 1916. He was educated at the College of Aurillac and at the lycées of Clermont-Ferrand and Poitiers. In 1872–1880 and 1889–1907 he was editor of the *Journal des Débats* and from 1907 he edited the *Revue des Deux Mondes*. He also held various public offices, principally in the Department of Foreign Affairs, was deputy for Cantal in 1881–1885 and 1889–1898 and senator in 1900. He was

ected to the academy in 1908. He published *Études historiques et diplomatiques* (1892) and numerous literary and political articles in his editorial capacity.

CHARMIAN, kār'mī-ān, or **CHARMION**, an attendant on Cleopatra in William Shakespeare's *Antony and Cleopatra*. After Cleopatra's suicide, Charmian killed herself.

CHARNAY, shār-nā', **Claude Joseph Désiré**, French traveler and archaeologist: b. Fleurioux (Fleurie), Rhône, France, May 2, 1828; d. Paris, Oct. 24, 1915. From 1857 to 1861 he traveled in Mexico for the French Ministry of Education and went on a number of expeditions to North and South America, Australia, and other countries. In 1880 he conducted an expedition to the ruined cities of Mexico. Charnay revisited the Mayan ruins of Yucatán in 1886. Among his publications are *Le Mexique: souvenirs et impressions de voyage* (1863); *Les anciennes villes du nouveau monde* (1885; Eng. trans. 1888); *Histoire de l'origine des Indiens qui habitent la nouvelle Espagne selon leurs traditions* (1903).

CHARNEL HOUSE, a chamber or building under or near churches, where the bones of the dead are deposited. In England the crypts of some churches were formerly used as charnel houses.

CHARNOCKITE, chār'nōk-it, name for a series of igneous rocks containing hypersthene and including, apart from hypersthene-granite (gneiss), other basic and ultrabasic types, among which are norites and pyroxenites. Charnockite, first described by Sir Thomas Henry Holland, is called after Job Charnock (d. 1693), the founder of Calcutta, India, whose tomb is made of a variety of such rock.

CHARNWOOD, chār'nwōd, 1st **CHARON** (GODFREY RATHBONE BENSON), English biographer and political leader: b. Langtons in Alresford, Hampshire, England, Nov. 6, 1864; d. London, Feb. 3, 1945. Educated at Winchester and at Balliol College, Oxford, where he was a one-time lecturer, he served as a liberal member of Parliament (1892-1895) with the sole purpose, as he claimed, of espousing Irish home rule. He was mayor of Lichfield from 1909 to 1911 and continued as councilor and alderman until 1938. In 1911 he was made a peer. Lord Charnwood attained renown for his biography *Abraham Lincoln* (1916), which was for long the most popular and authoritative one-volume work on the American president. He also wrote a life of *Theodore Roosevelt* (1923). Other publications include *According to St. John* (1926) and *Tracks in the Snow*, a detective story, reissued in 1927.

CHARNWOOD FOREST, wooded district, England, located in northwestern Leicestershire, about 15 miles south-southwest of Nottingham. With rugged terrain it rises gradually to its most elevated point, Bardon Hill, which is 912 feet high. There are granite quarries and some coal mines.

CHARNY, shār-nē', village, Quebec, Canada, located in Levis County, about 8 miles southwest of Quebec. It is washed by the Chaudière

River. An important divisional point of the Canadian National and Quebec Central railways, it has major railway repair shops. Pop. (1951) 3,300.

CHARON, kā'rōn, in classic mythology the son of Erebus and Nyx (Night), generally represented as a somewhat coarse, bearded, old man. It was his office to ferry the dead in his boat over the dark waters of the underworld. Each of the shades was obliged to pay him an obol, which was put at the time of the burial into the mouth of the deceased.

The traditions relative to Charon arose after the Homeric age, and it is thought that the myth was imported into Greece from Egypt. Charon is a familiar figure in literature after the 5th century B.C. The Etruscans seem to have associated him with all the horrors of death and depicted him with bestial face. Modern Greeks preserve the tradition in the figure of Charos or Charontas, the black bird or winged horseman, who carries people to the afterworld.

Consult Waser, O., *Charon, Charun, Charos* (Berlin 1898); De Ruyt, F., *Charun* (Rome 1934).

CHARONDAS, kā-rōn'dās, ancient Sicilian lawgiver, a native of Catana (modern Catania), flourished 6th century B.C. Of aristocratic background, he is said to have been a disciple of Pythagoras. He composed laws, probably in verse, which were adopted by some of the Greek-Chalcidic cities of southern Italy and Sicily, particularly Rhegium (modern Reggio di Calabria), and which won for their judiciousness and exactitude high praise from Aristotle in his *Politics*. According to legend he committed suicide, because he had violated one of his own laws.

CHAROPHYCEAE, kā-rō-fi'sē-ē, a class of algae, whose seven-member genera, *Chara*, *Nitella*, *Tolypella*, *Lychnothamnus*, *Lamprothamnion*, *Nitellopsis* and *Protochara*, are grouped in a single family, Characeae. The Charophyceae are classified currently by phycologists either in a separate division of the plant kingdom, the Charophyta, or as a class coordinate with the class Chlorophyceae, the green algae, under the division Chlorophyta. These divergent practices are representative of current views of their relation to other algae (q.v.). Although they possess pigments, storage photosynthate (starch) and flagellation similar to those of the Chlorophyceae, whatever their taxonomic disposition may be, they differ in the following morphological respects from other green algae. Their plant bodies, which are slender axes with whorls of branches (often called "leaves"), are in a majority of cases larger and coarser than those of Chlorophyceae; they may attain a length of five to six feet; the main axes may also be branched. Their nodal and internodal and verticillate construction, superficially suggestive of certain species of horsetails, *Equisetum*, are absent in Chlorophyceae, except in a few genera. Furthermore, the complexity of the axes, in those species in which nodal cells grow down as corticating layers, is unparalleled among the Chlorophyceae. Finally, the sex organs of the charalean genera are characteristic and unique and unlike those of other green algae.

Because certain species, especially of *Chara*, regularly become incrustated with lime (calcium carbonate), they are sometimes called "stone-

worts" or "brittleworts." Charalean genera grow in a variety of habitats, including lakes, ponds, quarries, sometimes in shallow water and sometimes in water as deep as 28 feet. The physical attributes of charalean habitats are variable: the bottom may be mucky, sandy, or rocky; various species have been found in slightly acid waters (at pH 5.7, *Nitella morongii*, for example) and in those which are markedly alkaline (pH 9.5, *Chara delicatula*).

Although a majority are freshwater forms, some flourish in markedly brackish water. In certain stations the plants seem to be not only seasonal in their development but also relatively ephemeral; in others, they have been observed to recur for more than 50 years. There is good evidence that the 292 recognized species of charalean algae vary in their tolerance of and requirements for special environmental conditions. Several species are cultivated in aquaria as agents of oxygenation.

The verticillate organization, large size, and complexity of the plants have been noted. Their development may be traced to the activity of a prominent, dome-shaped, apical cell, from which nodal and internodal segments are cut off with marked regularity. The elongate internodal cells are multinucleate and may or may not be covered with cortical cells, which originate from the node above and below; the internodal cells of Charophyceae are classical objects for observation of protoplasmic streaming. The plants are anchored to the substratum by branching, filamentous rhizoids.

Reproduction, other than by fragmentation of the plants and rooting of the fragments, is accomplished sexually. Sexuality is oogamous (involving large, nonmotile eggs and small, motile sperms, as in most animals). A majority of species are homothallic (male and female sex organs borne on the same individuals). The stalked sex organs are produced as short protuberances from the lateral branches or leaves and are sometimes clustered in homothallic species. The oogonium, the egg-producing organ, contains a single egg cell, whose cytoplasm is densely filled with starch and other stored metabolites; it is surrounded by a single layer of spirally twisted cells, the tube cells, whose apices are delimited to form a group of crown cells. The male organ, the antheridium, is somewhat globose and complex in organization. Its surface is composed of eight shield cells which become reddish orange at maturity. Attached to the inner surface of each of these is a radially elongate cell, the manubrium; the manubria bear somewhat isodiametric cells, the capitula, at their inner poles; from these branching, colorless rows of cells the antheridial filaments are generated. Each cell of the latter produces a single sperm, which at maturity is liberated through a pore from its mother cell and through fissures between contiguous shield cells.

The biflagellate sperms reach the egg through small passageways, developed by slight separation of the tube cells just below the crown. Parthenogenetic plants, whose eggs develop without fertilization, are known. The fertilized eggs, zygotes, become dark colored and are shed ultimately from the parent plant; the inner walls of the tube cells, adjacent to the oogonial surface, persist and thicken and are present as spiral markings on mature zygospores in both living and fossil charalean genera. Following a period of dormancy, the zygospores germinate into young plants. Meiosis probably occurs at zygospore germination. See also PLANTS AND PLANT SCIENCE—Classification, Morphology, and Evolution (Algae and Fungi).

HAROLD C. BOLD,
Vanderbilt University.

CHAROST, shā-rō', DUKE OF. See BÉTHUNE.

CHARPENTIER, shār-pān-tyá', *Gustave*, French composer: b. Dieuze, Lorraine, France, June 25, 1860. After studying at the conservatory of Lille, he was a pupil of Émile Pessard

and Jules Massenet at the Paris Conservatory. For his cantata *Didon* he won the Grand Prix de Rome in 1887. In Italy he wrote *Napoli*, a symphony, *Impressions d'Italie*, an orchestral suite, and *La vie du poète*, a symphonic drama produced at the Grand Opéra in 1892. His greatest and most notable work was, however, *Louise*, an opera produced at the Opéra Comique in 1900. The libretto, frequently ascribed to the composer, was by Saint-Pol-Roux (Paul Roux). *Louise* was presented also in Germany, England, and the United States with great success. A second opera, *Julien* (1913), failed. Besides three operas, *Marie*, *Orphée*, and *Tête rouge*, Charpentier set to music poems by Charles Baudelaire and Paul Verlaine. He was elected to the French Academy of Fine Arts in 1912.

CHARR, genus of fishes. See CHAR.

CHARRAN, ancient Mesopotamian city, now in Turkey. See HARAN.

CHARRON, shā-rōn', *Pierre*, French Roman Catholic theologian and philosopher: b. Paris, France, 1541; d. there, Nov. 16, 1603. After studying law at Orléans and Bourges, he practiced for six years as a parliamentary advocate and then turned his attention to theology. Gaining much fame by his sermons, he was appointed court chaplain to Queen Margaret, the wife of King Henry IV of France, who protected him on several occasions. Charron went in 1589 to Bordeaux and became very intimate with Montaigne, who influenced him considerably. His principal works are *Traité des trois vérités* (1594) and *Traité de sagesse* (1601). The dogmatic zeal of the former drew upon him the rebuke of Philippe de Mornay (Duplessis-Mornay), the Huguenot leader, while the latter's pessimism and skepticism exposed him to a charge of atheism and led to official condemnation of the treatise.

CHARRUAS, chār-rōō'áz, a fierce, now virtually extinct, dark-skinned Indian people of South America inhabiting present-day Uruguay and parts of southern Brazil. They lived by hunting. Expert horsemen, and of sullen temperament, they long resisted European colonization of the area.

CHART. The term as used herein is restricted to maps used for navigation, but it is also used for any graphic delineation of statistical or other scientific material, such as charts of production, charts showing organization of government, and time charts of history. For these see DIAGRAM. The word "chart" comes from Greek *chártēs* and Latin *carta*, meaning "leaf of papyrus," "paper."

History.—The history of charts is almost as old as the history of maps. Indeed the first scientific maps were made by navigators, and the fundamental principles of geography, such as the size, shape, motions of the Earth, latitude and longitude were first defined for their use in navigation. The ancient Greek *portolanos*, or harbor book, was probably accompanied by charts, and we can safely assume that the ancient Phoenicians had good charts, as we have positive knowledge of the chart of the *oekumene* (habitable world) by Marinus of Tyre of about 100 A.D., from Claudius Ptolemy, who often referred to it.

The most important chart of history is the portolan chart of the Middle Ages. This famous chart delineates the coast of the Mediterranean with surprising accuracy. Its first copy dates from 1300 (Pisa) and it was copied over and over again with some modifications until 1620. So good was this chart that it was used for actual navigation for over three centuries.

The famous maps of the Great Discoveries, such as the Juan de la Cosa map of 1500 and the Ribero map, could be called charts rather than maps, as their emphasis was more on the sea than on the land. The first atlas of charts is *Spiegel der Zeaveardi* of Lucas J. Waghenar, published in 1584. The Dutch were the leaders in chart making during the 17th century. After the *Neptune François* of 1693 the best charts came from Paris, which in turn was eclipsed by London in the second half of the 18th century. The *English Pilot*, the charts of Joseph F. W. Des Barres, Thomas Jefferys, and others represented the high tide of private chart making. Private undertaking, however, was unable to cope with the demands of the navy, and the Royal Hydrographic Office was founded in 1795. Since that time, the British Admiralty has been the leading producer of charts the world over.

The United States Coast Survey was founded in 1807 and was organized under Ferdinand Hassler, a Swiss cartographer. The first charts appeared in 1845, and since then charts of all the coasts of the United States and its dependencies have been produced. As this office also provides first- and second-order triangulation for all surveys of the United States, its name was changed in 1878 to United States Coast and Geodetic Survey after the great transcontinental arc of triangles from Atlantic to Pacific was carried through. See COAST AND GEODETIC SURVEY, UNITED STATES.

Charts of foreign waters are published by the United States Hydrographic Office of the Navy Department, founded in 1806. This is done partly by compilation, partly by original surveys. This office also publishes the monthly *Pilot Charts*. Other charts deal with earth magnetism, astronomy, great circle navigation (gnomonic charts). Both offices publish charts for aerial navigation (airway maps). See HYDROGRAPHIC OFFICE, UNITED STATES.

The charts of the Great Lakes are prepared by the Survey of the Northern and Northwestern Lakes of the Corps of Engineers (founded 1841). The charts of the Mississippi River are periodically published by the Mississippi River Commission in Vicksburg, Miss.

Among the other nations, France, Germany, the U.S.S.R., Japan, Netherlands, Denmark, Spain, Portugal, Italy, Norway, and Chile are the most important producers of charts.

Scales and Projections.—Charts, unlike topographic sheets, are published on very variable scales. The reduction of general charts of the seas and oceans goes into millionths; coast charts show a mile in 1–10 inches, while harbor charts have still larger scales. Coasts are of widely different importance, and uniformity of scale is not practical. The prevailing Mercator projection in itself would preclude such uniformity. Indeed the scale is not even given on small-scale Mercator charts, but can be read on the side margins: 1 minute of latitude equals 1 nautical mile.

The preference for the Mercator projection

is due to the unique property of this network: that it shows compass directions (rhumb lines) as straight lines, and it makes plotting of courses easy. If we place an evenly divided compass rose or protractor over any point of the map, the rhumb lines (loxodromes, compass azimuths reckoned from true north) will have the correct bearing.

The gnomonic projection shows great circle directions as straight lines, and gnomonic charts of each ocean are published, for plotting trans-oceanic routes. For actual navigation, these great circle sailing routes are transferred to Mercator charts. The United States Coast and Geodetic Survey published some charts in the polyconic projection because the geodetic positions were plotted on polyconic base sheets.

Symbols.—The symbols of charts are the result of long development and are much the same the world over. The detail of land areas is shown only as far as visible from the sea, or as it has any bearing on harbors or navigation. Buoys, lights, shoals, rocks, signals, piers, landings, harbor facilities, dredged channels, anchorages, and types of bottom are recorded by an elaborate set of symbols or abbreviations. Soundings are often recorded in feet in shallows, and in fathoms in deep water, and meters are used in foreign charts. Datum plane for soundings is mean low water (mean lower lows in the Pacific). On very variable tides a still lower level may be chosen. Heights are usually reckoned from mean high water level, as this line is clearly visible. Charts usually give information about tides and currents. Compass roses have usually an outer dial divided in degrees reckoned from true north and an inner dial divided in points ($11\frac{1}{4}^\circ$) counted from magnetic north. Isogonic lines are also shown.

Marine Surveys.—These surveys have been greatly facilitated by echo sounding and by airplane photography. Intricate shore lines of coral or mangrove can now be plotted with ease and great accuracy. The location of the surveying vessel is obtained by radio acoustic sounding in which a sound signal from the vessel releases radio signals from two shore stations of known location. See SUBMARINE SIGNALING.

Pilot Charts.—Published monthly by the United States Hydrographic Office and separately for each ocean, these charts show winds, currents, isogonic lines, storm tracks, floating icebergs or derelicts, sailing routes and give a wealth of information on oceanographic data.

Aeronautical Charts.—These charts or airway maps are usually on the scale of 1:500,000 or 1:1,000,000, and most are on Lambert conformal conic projections, which, within the limited area of a sheet, have fairly good azimuths. The charts show roads, railways, cities, rivers, and easily visible land marks. Relief is shown by 1,000-foot contour lines and altitude tints in conventional colors. All information pertaining to flying, such as airports, landing fields, radio beacons, and signals are overprinted, usually in red. Airway maps are published either in the form of regular sections or showing strips about 80 miles wide. In the United States, the Hydrographic Office, the army, and the Coast and Geodetic Survey all publish airway maps. See also MAP; NAVIGATION.

ERWIN RAISZ,
Lecturer on Cartography, Institute of Geographical Exploration, Harvard University.

CHARTER, a document by which a sovereign power grants permanent or continuing rights and privileges to a person or persons, corporation or institution, colony or municipality. Originally it had the broader sense, now obsolete, of a conveyance of land. The medieval charters ranged from a grant of political rights by a sovereign to an entire people—like the Magna Carta (q.v.) or Great Charter of England—or to a section of the country (for example, the *Charte aux Normands*, setting forth the privileges granted to the Normans in 1315 by King Louis X of France), down to permissive acts for abbeys and colleges or trading companies (see **CHARTERED COMPANIES**). The French Constitution of 1814, granted by Louis XVIII on the restoration of the monarchy, is known as the *Charte* or the *Charte Constitutionnelle*. In modern usage the term is generally restricted to the charters of municipalities, corporations, and institutions, with the major exception of the Charter of the United Nations (see **UNITED NATIONS, THE**).

Colonial Charters.—The charters for the American colonies were usually distinguished from patents by the granting of specific privileges of jurisdiction and legislation and, in general, the powers needed to establish and continue a self-regulating community, instead of mere general grants of land and rights of settlement. The two terms were, however, often used loosely as interchangeable. Thus, in acknowledging receipt of their charter in 1662, the Connecticut officials acknowledged also the "old charter," meaning the Warwick Patent. Strictly speaking, all the colonial charters were patents, as granted by the king under letters patent, but in usage only (1) the grants to individuals were commonly termed patents, the word charter being reserved for (2) those to companies and (3) those to colonies already established. Of the three types, the first includes the patents to Cecilius Calvert, 2d Baron Baltimore, for Maryland in 1632; to Sir Ferdinando Gorges for Maine in 1639; to the duke of York (later James II) for New Netherland (New York) in 1664; and to William Penn for Pennsylvania in 1681. The second comprises those to the Virginia Company in 1606, 1609, and 1612; the Plymouth and London companies in 1606; the Council for New England in 1620; the Massachusetts Bay Company in 1629; the proprietors of Carolina in 1663; and the trustees of Georgia in 1732. Included in the third class are Rhode Island (1643; superseded 1663) and Connecticut (1662). The legal nature of these documents was keenly disputed. According to the English view, they were concessions granted by the government for political reasons and revocable at its pleasure; the title to the lands as well as to political privileges lay with the government, and its right to vacate either was limited only by policy; and charter governments had only such powers as were specifically given them in the charters. The colonial view was that the charters were compacts between the government and the colonies, in consideration of the latter having cleared and taken possession of the territory and annexed it to the crown; and that the crown possessed only political rights there, the land title being derived from purchase and occupation and the colonists' own courage and labor. See also **COLONIAL GOVERNMENT, PROPRIETARY**.

Municipal and Private Charters.—In the United States charters are granted by acts of the several state legislatures or by the national gov-

ernment. The act by which a municipality is organized is termed a charter. It is distinguished from a private charter, however, in that it is not a contract; the municipality has no vested rights; and the charter can be altered or repealed at any time by the legislature. A private charter, on the other hand, is a contract which cannot be repealed or modified by the public power unless such liberty has been expressly reserved in the charter itself. See also **CORPORATIONS, LEGAL—Charter; DARTMOUTH COLLEGE CASE, THE**.

CHARTER OAK, a tree nearly seven feet in diameter, formerly in Hartford, Conn., which blew down in a storm on Aug. 21, 1856, when its age was computed to be nearly 1,000 years. A section of its trunk was preserved in the rooms of the Connecticut Historical Society; the remainder—believed to rival in miraculous powers of reproduction the loaves and fishes or the *Mayflower* furniture—was kept or sold for small souvenirs. It is thus venerated from a tradition, first accredited to it in 1789, that in a hollow of it was concealed the charter of Connecticut rescued from Sir Edmund Andros (q.v.) in 1687; earlier ones specify an elm, others the houses of different persons. This is of little moment, but the adventures of the charter form a mystery which investigations, instead of illuminating, render utterly insoluble. The contradiction of unquestionable facts is absolute. The story without these is sufficiently peculiar. James II, wishing to make Connecticut a part of his consolidated New England under Andros, found its charter in the way; and as the colony declined to surrender it, he brought writs of quo warranto to vacate it, the last of which was returnable in February 1687. To delay or avoid voluntary surrender, yet escape forfeiture and entire outlawry of rights, the colonists replied that they would much rather stay as they were, but if they could not, preferred a provincial union under Andros over annexation to any other province. The council chose to consider this a formal waiver of charter rights, and dropped proceedings under the writ; and on Oct. 31, 1687, Andros rode over from Norwich to Hartford, under orders to assume the government. Calling the governor and council together, he demanded surrender of the charter according to their dutiful assurances. The meeting was secret; what happened we learn only from tradition and the brief account of an intimate friend of the actors. The colonial officials protested and debated until after dark; that this was prearranged is not only morally certain in itself, but Benjamin Trumbull's account of a long speech by the governor, to no conceivable purpose otherwise, deepens the certainty. Candles were lighted; the charter was (or the charters were) at last brought in and laid on the table; suddenly some officious candle snuffers put out all the lights, and when they were relighted no charter was to be seen. But if Andros had no longer a charter to suppress, equally the colony had no longer one to appeal to; the old government was just as effectually extinguished as if they had let him have the paper; they cannot have foreseen a revolution in England, and it is not evident what they intended to do with it. Most likely, from their previous actions, it was merely to save their face from the humiliation of a formal surrender. There was no outcry by Andros, no charge made against the officials, no appearance of ill will to them, no report of the affair to England, seem-

ingly no disclosure of it to the train of Massachusetts magnates who accompanied him (and may or may not have attended the meeting), or to anyone else; and (perhaps the most curious of all the circumstances of this curious affair) both our informant and tradition stop short at the relighted candles and the missing document, and give no hint what Andros said or if he said anything, or whether he seemed puzzled or offended, or any of the immediate sequelae of the business. The governor, Robert Treat, had called a meeting of the General Court, which accepted the situation and the annexation; the secretary inscribed it on the colonial records and wrote "Finis" on them; and the next day Andros publicly proclaimed his commission. When James was overthrown and Andros with him, the colony resumed its government, appealed to its charter brought from hiding, and the English authorities admitted without trial that it had never been vacated. But that was chance and not foresight. This, however, is only the beginning of mystery. The charter, obtained by Gov. John Winthrop from Charles II's council in April 1662, was engrossed in duplicate, and the official fees are entered on the English records. No other copies were made, nor could have been unless both the others were lost; and neither was lost. The first copy was sent to the colonial government, which acknowledged receipt of "the charter, the duplicate and the old copy of the former charter [that is, the Warwick Patent]." Duplicate of what? It is usually assumed to mean of the charter; but the facts to be cited prove that it was of the patent. Winthrop was to bring over the duplicate of the charter with him and a legislative committee was appointed to receive it from him. That he did not is conclusively shown by a letter from the colony to its agent, William Whiting, in 1686, instructing him to obtain it from James Porter in London, with whom Winthrop had left it, and use it in defending the colony's rights before the council. That Winthrop may have taken it across once more on official business, and left it there, is barred out by the fact that he never visited England again. That Whiting sent it back within the next year is equally negated by the fact that he continued to need it there and the colony did not need it at all, that he would not have sent it without orders and they gave him no such orders, and that in his correspondence there is no letter of transmittal. Furthermore, a legislative committee of 1715 voted a money acknowledgment to Joseph Wadsworth for safely preserving the "Duplicate Charter" when "our constitution was struck at." It is absurd to suppose they made him the grant for preserving a second copy when they had one safe already. Obviously, the one he preserved was the only one they had. On the other hand, Roger Wolcott, the first narrator (1759), distinctly says that "the charters were set on the table," and that when the candles were relighted the charters were gone. Still more specifically, President Ezra Stiles of Yale writes in his *Itinerary*, as from Wolcott, that Nathan Stanley took one copy and Governor Joseph Talcott's father the other. Wolcott was only eight at the time; but by 1714 he was in the council, in 1715 was on the very committee which made the grant to Wadsworth, and was certainly intimate with many who were present at the scene and probably helped arrange it. We have, then, the certain fact that there was but one copy of the charter in America in 1687.

set against the positive assertion of one who must have known, that two were abstracted. Still a third mystery is that Wadsworth was not present at the meeting and could not have taken the paper; that Wolcott, who publicly honored Wadsworth as the savior of the charter, privately gives all the credit to others and does not even mention Wadsworth, and that the names of the persons he cites are really those of members present; and that if one of the actual abstracters passed it to Wadsworth waiting outside, he and not they should receive public acknowledgment. We can guess at solutions to these problems, but all solutions are guesses alike.

ALBERT C. BATES,

Librarian Emeritus, Connecticut Historical Society.

CHARTER PARTY, a contract executed by the freighter and the master or owner of a ship, containing the terms on which the ship or a principal part thereof is hired to freight. The master or owner usually binds himself that the goods freighted shall be delivered (dangers of the sea excepted) in good condition at the place of discharge, and agrees also to equip the ship complete and adequate to the voyage. The charterer is bound to furnish the cargo at the place of lading and to take delivery at the port of discharge within a specified period.

CHARTERED COMPANIES, trading companies which came into existence as a result of special charters granted to them by the sovereign authority of the state. The charters usually granted the companies (which sometimes were state supported) well-defined rights and privileges; stated the localities in which the rights were to be exercised; and imposed certain obligations on the companies thus created. The earlier companies were generally either associations of merchants engaged in foreign trade, or the agencies through which colonization projects were carried out. As such, they played a large part in the overseas expansion of the European nations, enabling the expense of long journeys to little-known places to be shared among the stockholders in the enterprise. Their reward was the monopoly of trade with a certain area, and in that area they exercised legislative, military, and diplomatic powers.

In England the first charters were granted to branches of the Hanseatic League (q.v.), which traded in England for 700 years until the Steel-yard in London was closed by Queen Elizabeth I in 1598. The origin of the English companies is found in the Merchants of the Staple, an association primarily interested in exporting wool, which remained in existence until the 18th century. The largest of the early companies was the Merchant Adventurers (1359), a development of the early trade guilds (see **MERCHANT ADVENTURERS, THE COMPANY OF**).

The chartered company in its more modern sense developed mainly during the 16th century, notable examples being the Eastland (1404), Muscovy (1555), Levant (1581), English East India (1600), Dutch East India (1602), and Hudson's Bay (1670) companies (see **EAST INDIA COMPANIES; HUDSON'S BAY COMPANY, THE**). In France, from 1599 to 1770, when the French East India Company (founded in 1664) was dissolved, more than 70 companies were established. Spanish companies, trading with Cen-

tral America and the West Indies, were formed in the first half of the 18th century.

Much of the early colonization of the Western Hemisphere was undertaken by companies chartered for the purpose, among them the Dutch West India Company (1621; see DUTCH WEST INDIA COMPANY, THE), the Massachusetts Bay Company (q.v., 1629), the French Royal West India Company (1664), and the Santo Domingo Company (1698). The Plymouth Company (see PLYMOUTH COMPANY, THE) and the London Company (q.v., later the Virginia Company) were granted charters in 1606 by James I to locate colonies in North America, and Jamestown, the first permanent English settlement in North America, was founded by the London Company in 1607.

By the middle of the 19th century these companies had largely disappeared, the English East India Company being finally dissolved in 1874. During the last 20 years of the 19th century, however, there was a revival in Europe, notably in Great Britain, of the system of chartered companies for trading and colonization purposes. These companies were not privileged or monopolistic in the sense that the 16th and 17th century companies were, and their sovereignty, being subject to the control of the home governments, was limited. Their main achievements lay in opening up the territories in which they operated, developing trading facilities, and laying foundations of settled administration. It has been estimated that in Africa alone they added about 1,700,000 square miles of territory to the British Commonwealth. The most notable of these later companies were the North Borneo (1881), Royal Niger (1886), British South Africa (1889), and German East Africa (1884) companies, all of which have since been liquidated.

H., *The Early Chartered Companies* (London 1896); Hannay, David, *The Great Chartered Companies* (London 1926); *The Cambridge History of the British Empire*, 8 vols. (Cambridge, England, 1929-36); Lipson, Ephraim, *The Economic History of England*, vol. 2, chap. 2, 4th ed. (London 1947).

CHARTERHOUSE, a celebrated school and charitable foundation, Godalming, Surrey, England. In 1371, Sir Walter de Manny (q.v.) built and endowed in London a priory for Carthusian monks—hence the name, which is derived from *maison Chartreuse*, a religious house of the Carthusian Order. After the dissolution of the monasteries (1535) it passed through several hands until it came into the possession of Thomas Sutton, who, in 1611, obtained letters patent from James I and converted it into a hospital, richly endowed, consisting of a master, a preacher, a head schoolmaster, and 40 "poor scholars" (boys) and 80 "indigent gentlemen," together with a physician and other officers and servants. The pensioners, "poor brethren," must be over 50 years of age and members of the Church of England.

The school was removed to new buildings near Godalming in 1872, and since then the scholars have been selected by examination instead of being nominated by the governors, as laid down in the original charter. In 1953 there were 60 scholarships, the remainder of the 600 students at the school paying fees of £300 a year. The special garb of the scholars has been discarded, and Charterhouse is one of the great public schools of England. Among the famous men who

received their education at Charterhouse were Isaac Barrow, Joseph Addison, Sir Richard Steele, John Wesley, Sir William Blackstone, George Grote, Connop Thirlwall, Sir Henry Havelock, John Leech, and William Makepeace Thackeray (qq.v.). Charterhouse and one of its poor brethren, Colonel Newcome, were immortalized by Thackeray in *The Newcomes*.

In 1939 the pensioners, 60 in number, were also moved to Godalming, and no new ones were admitted since that date. By 1950 their numbers had been reduced to 13.

Consult Haig Brown, William, *Charterhouse Past and Present* (Godalming 1879); Taylor, W. F., *The Charterhouse of London* (London 1912); Kent, William, ed., *An Encyclopaedia of London*, new rev. ed. (New York 1951); *The Public and Preparatory Schools Year Book* (London, annually).

CHARTERS TOWERS, city, Australia, situated in Queensland, near the Burdekin River, 75 miles southwest of Townsville, with which it is connected by rail. There are copper, silver, and gold mines nearby. First settled in 1871-1872, when gold was discovered in the area, Charters Towers was incorporated in 1877. Pop (1947) 7,561.

CHARTIER, shâr-tyä', Alain, French writer and diplomat: b. Bayeaux, France, 1385?; d. Avignon, after 1433. Educated at the University of Paris, he entered the service of the dauphin (later Charles VII) in 1418, becoming secretary of the royal household in 1422. Between 1424 and 1428 he was employed on various diplomatic missions, including one to Scotland in 1427 to make arrangements for the subsequent marriage of Margaret of Scotland and the dauphin (later Louis XI). An ardent patriot, he wrote *Le livre des quatre dames* (1415), *Quadrilogue invectif* (1422), *Traité de l'espérance* (1428), and other works to rally the French in support of the royal house, whose fortunes had been in eclipse since Agincourt (1415). Of more enduring value is his graceful poetry, including *Lai de plaisance* (1413-1414), *La belle dame sans merci* (1424) and *Bréviare des nobles* (c. 1424).

Consult Hoffman, E. J., *Alain Chartier* (New York 1942).

CHARTIER, Émile Auguste (pseudonym ALAIN), French philosopher and essayist. b. Mortagne, France, March 3, 1868; d. Le Vésinet June 3, 1951. Educated at the École Normale Supérieure, he became a professor of philosophy at the Lycée Henri IV in Paris, and through his teaching and extensive publications exercised a wide influence on French thought in the years between World Wars I and II. His most characteristic work was the *propos*, a short, aphoristic essay embodying his views on ethics, which emphasized the importance of the individual conscience and of resistance to power. Collections of *propos* include *Les propos d'Alain* (1920), *Propos de littérature* (1933); and *Propos de politique* (1934). Among Chartier's other published works are *Le citoyen contre les pouvoirs* (1925); *Les idées et les âges* (1927); *Les dieux* (1934); *Histoire de mes pensées* (1936); *Souvenirs de guerre* (1937); and *Les saisons de l'esprit* (1937).

CHARTISM, a 19th century English working-class movement whose primary purpose was the attainment of certain political reforms. The

Reform Bill of 1832 had failed to bring expected advantages to the working class; the Poor Law Amendment Act of 1834 was unpopular; and a period of general commercial depression and a succession of bad harvests had produced widespread suffering. The resultant discontent found expression in the People's Charter, a document prepared by a committee of workingmen and members of Parliament and published in 1838. Reforms were demanded under six heads: (1) universal suffrage, or the right to vote conferred on every male 21 years of age or over, of sound mind, unconvicted of crime, and a native of the United Kingdom, as well as on every foreigner possessing the same qualifications, who had resided in the United Kingdom for more than two years; (2) equal electoral districts; (3) vote by ballot; (4) annual Parliaments; (5) no property qualification for members of Parliament; and (6) payment of members of Parliament.

At first some members of the middle class supported the movement, but they became estranged from it, and the Chartists became more and more a distinctively working-class group. The movement was not purely political, for it also aimed at the improvement of general social conditions. Joseph Rayner Stephens, one of its leaders, is quoted as saying: "Chartism is no political movement where the main point is gaining the ballot. . . . The Charter means a good house, good food, prosperity, and shorter working hours." Immense meetings were held throughout England, and popular excitement was high. Some of the Chartists advocated physical force as the only effectual means of obtaining their demands. Meanwhile, in June 1839, a petition in favor of the charter, signed by 1,280,000 persons, was presented to the House of Commons, which rejected it on July 12. The Chartists became increasingly exasperated, and in November 1839 a riot took place in Newport, in which a number of persons were killed and wounded. In 1842 there were serious riots in the north and the Midlands. A great demonstration was planned in London in 1848, but the precautions taken by the government in enrolling special constables and other preparations for defense greatly reduced the size of the gathering, which was easily dispersed. The decline of Chartism dates from that year. The repeal of the corn laws (1846)—which the Chartists had opposed as likely to benefit only the middle class—and the resulting great expansion of trade produced an improvement in economic conditions, and social unrest gradually died down.

Consult Hovell, Mark, *The Chartist Movement*, new ed., ed and completed by T. F. Tout (London 1925); Hammond, J. L. Le B., and Hammond, Barbara, *The Age of the Chartists, 1832-1854* (London 1930); Cole, G. D. H., *Chartist Portraits* (London 1941); Dodds, J. W., *Age of Paradox: A Biography of England, 1841-1851* (New York 1952).

CHARTON, shâr-tôn', Édouard (Thomas), French writer and politician: b. Sens, France, May 11, 1807; d. Versailles, Feb. 28, 1890. He began his career as a lawyer, became interested in journalism, and helped to found several magazines, including *Magasin Pittoresque* (1833), *L'Illustration* (1843), *L'Ami de la Maison* (1856), and *Le Tour du Monde* (1860). He also published a number of historical works, among them *Voyages anciens et modernes* (1854-1857) and *Histoire de France illustrée* (with Henri Léonard Bordier, 1859-1860). In 1870 he served as prefect of the Department of Seine-et-Oise, and in the follow-

ing year was elected to the Chamber of Deputies. From 1878 he served in the Senate.

CHARTAN, shâr-trân', Théobald, French painter: b. Besançon, France, Jan. 21, 1849; d. Neuilly-sur-Seine, July 17, 1907. He studied art under Alexandre Cabanel, and in 1877 was awarded the Grand Prix de Rome for *La prise de Rome par les gaulois*. Among his many religious and historical paintings are *La vision de saint François d'Assise*; *Vincent de Beauvais et Louis XI à Royaumont*; and *Cérémonie du centenaire de Victor Hugo*. His *Signing of the Peace Protocol at Washington*, depicting an episode in the Spanish-American War, was presented to the United States government by Henry C. Frick. Chartan executed the portraits of many eminent men, including Pope Leo XIII, Sadi Carnot, and of presidents William McKinley, and Theodore Roosevelt.

CHARTRES, shâr'tr', Duc DE (ROBERT PHILIPPE LOUIS EUGÈNE FERDINAND D'ORLÉANS), French nobleman: b. Paris, France, Nov. 9, 1840; d. Dec. 5, 1910. A grandson of King Louis Philippe, he went into exile with his family in 1848 and lived in Germany and England for 10 years. He then went to Italy, where he attended a military school in Turin and fought in the war against Austria. Going to the United States in 1861, he served on the staff of Gen. George B. McClellan in the following year. After the establishment of the Third Republic in 1870, he returned to France, where he served in the army under the pseudonym of Robert le Fort, rising to the rank of major by the close of the Franco-Prussian War. Subsequently he became under his own name a major in the Chasseurs d'Afrique, and in 1878 was promoted to the rank of colonel. In 1883, however, he was suspended from active service, and three years later his name was removed from the army list under a law excluding members of former reigning families from serving in the army or navy, and he went into exile once more.

CHARTRES (ancient AUTRICUM and CIVITAS CARNUTUM), city, France, capital of the Department of Eure-et-Loir, situated on the left bank of the Eure River, 48 miles southwest of Paris. It is built on the slopes of a hill rising from the river and is surrounded by tree-shaded boulevards. The streets of the lower section, which has many medieval and Renaissance houses, are narrow and winding. Besides the great Gothic cathedral (see CHARTRES CATHEDRAL), the chief points of interest are the Church of St.-Pierre, built in the 12th and 13th centuries, which has fine enamel paintings of the Twelve Apostles; the former episcopal palace, now the Musée des Beaux-Arts, which has a collection of paintings, enamels, ivories, and tapestries; and the town hall (1614), which was damaged in 1944. The city serves as a trading center for the rich agricultural and cattle-raising plain of Beauce, and has manufacturing establishments producing woolen textiles, hosiery, leather goods, agricultural machinery, and beverages.

In Roman times Chartres was the seat of the Gallic tribe of Carnutes. Later it belonged to the counts of Blois, who sold it to King Philip IV in 1286. It was occupied by the English from 1417 to 1432. During the Franco-Prussian War it was taken by German troops. The city sustained

some damage in World War II. Pop. (1946) 23,509.

CHARTRES CATHEDRAL. One of the greatest masterpieces of Gothic architecture, the Cathedral of Notre-Dame de Chartres surmounts the hill on which the city of Chartres stands. Erected on the site of a Romanesque cathedral that burned in 1020, it was in large part completed between 1194 and 1260. The triple west door—known as the Portail Royal because of its elongated statues of kings and queens—and the lower part of the façade date from the late 12th century; the upper part of the façade and the great rose window, from the early 13th century. The south spire, which is contemporary with the façade, rises to a height of 344 feet; the north spire, not completed until the 16th century, is 377 feet high. The magnificent nave, about 130 feet long, 55 feet wide, and 120 feet high, is lighted by 13th century stained glass windows, generally considered the finest medieval windows. The choir is enclosed in stone carved with statues depicting the lives of Christ and the Virgin Mary.

The cathedral is intimately connected with the history of France. Before it was completed, in 1146, St. Bernard of Clairvaux preached the Second Crusade there, and in 1594 it was the scene of the coronation of Henry IV.

Consult Vigneau, André, *La cathédrale de Chartres* (New York 1934); Adams, Henry, *Mont-Saint-Michel and Chartres*, reissue (Boston 1936); Stoddard, W. S., *The West Portals of Saint-Denis and Chartres* (Cambridge, Mass., 1952).

CHARTREUSE, shār-trüz' (Fr. shār-trüz'), a color tint extending in range from a pale yellow with a greenish cast to a pale, light green with a pronounced yellowish tinge. A slightly neutral tint—that is, having a quiet, slightly grayish tone—it has two extremes which are often identified as chartreuse yellow and chartreuse green. The color is similar to, and derives its name from, the liqueur chartreuse (q.v.).

CHARTREUSE, a liqueur with a brandy base distilled from aromatics according to a secret formula given to the Carthusian monks of La Grande Chartreuse, France, in 1607, and perfected by them in 1757. Expelled from France in 1903, the monks took their formula to Tarragona, Spain, where they continued to produce and sell the liqueur. In 1938 they were permitted to return to France.

Chartreuse is of two types: yellow, which is 86° proof; and green, 110° proof.

CHARTREUSE, La Grande, the principal monastery until 1903 of the Carthusians (q.v.), situated in the Department of Isère, France, near the village of St.-Pierre-de-Chartreuse and about 12.5 miles north of Grenoble. It was founded in 1084 by St. Bruno of Cologne (q.v.), but the present buildings date from 1676. From the mother house the order spread to other European countries. During the French Revolution the monastery was confiscated, and the monks were secularized or banished. In 1816, the Carthusians were permitted to reoccupy the buildings as tenants of the government, which charged them a nominal rent. Under the Associations Law of 1901, however, the monks were once more dispossessed, and in 1903 they moved to Tarragona, Spain, taking with them the formula for their celebrated liqueur, chartreuse (q.v.). In 1938 the

Carthusians were permitted once more to occupy La Grande Chartreuse.

CHARTREUSE DE PARME, La (THE CHARTERHOUSE OF PARMA), published in 1839, is considered the best of the novels of Stendhal (Henri Beyle). In time it belongs to the romantic movement, and it has highly romantic passages, but there are others which seem to foreshadow naturalism. The story opens in 1796 and passes rapidly to the decade following the Battle of Waterloo. The scene is laid chiefly in Milan and Parma; the plot, ingenious but too involved, deals with the intrigues of a petty Italian court; and the interest, for both author and reader, lies almost entirely in characterization. Fabrice del Dongo, the hero, his military career closed by the fall of Napoleon, turns his ambition toward the church, and after adventures that show him, in Charles Augustin Sainte-Beuve's phrase, "like an animal given over to his appetites or like a wanton child who follows his caprices," dies an archbishop in a Carthusian monastery. The heroine, Duchess Sanseverina, beautiful, witty, and passionate, murders, marries, and forgets her marriage vows in Fabrice's behalf, resembling some of the female figures of the Italian Renaissance. Count Mosca is a diplomatic courtier, ingeniously unscrupulous in reconciling the duties of his station with his desires. Palla, a political outlaw and highwayman, the philandering agent of the duchess' designs, is an interesting age fellow of Victor Hugo's Hernani. All four characters illustrate as many phases of Stendhal's conception of the unreasoning fatality of love.

CHARTULARY, kār'tū-lēr-i, a collection or register of charters. In the Middle Ages, when any ecclesiastical or secular body came to possess a considerable number of charters, it was customary for safety and convenience to have them classified and copied into a book or roll, called a chartulary. Although they have been traced in France as far back as the 10th century, it was not until the 12th and 13th centuries that chartularies became common. They were kept not only by all kinds of religious and civil corporations, but also by private families. Copies of valuable historical documents, whose originals have been lost, have been found in chartularies.

CHARYBDIS. See SCYLLA AND CHARYBDIS.

CHASE, Frederic Henry, English prelate: b. London, England; Feb. 21, 1853; d. Bexhill, Sept. 23, 1925. He was educated at King's College School, London, and at Christ's College, Cambridge, from which he was graduated in 1876. In the same year he was ordained deacon, and in 1877 priest, of the Church of England. From 1876 to 1879 he served as curate of Sherborne, and from 1879 to 1884 as curate of St. Michael's, Cambridge. He was lecturer in theology at Pembroke College (1881-1890) and at Christ's College (1893-1901); principal of the Cambridge Clergy Training School (1887-1901); vice-chancellor of Cambridge (1902-1904); and Norrisian professor of divinity (1901-1905) and president (1901-1906) of Queen's College. Appointed bishop of Ely in 1905, he served in this office until he retired in 1924. Chase contributed much to the revision of the Book of Common Prayer. His published works include *Chrysostom* (1887);

The Lord's Prayer in the Early Church (1891); *Old Syriac Element in Codex Bezae* (1895); *Syro-Latin Text of the Gospels* (1897); *The Credibility of the Book of the Acts* (1902); *Confirmation in the Apostolic Age* (1909); *Belief and Creed* (1918); and *The Creed and the New Testament* (1920).

CHASE, Frederick Lincoln, American astronomer: b. Boulder, Colo., June 28, 1865; d. near there, Nov. 8, 1933. He received his B.A. degree from the University of Colorado in 1886, and his Ph.D. from Yale University in 1891. In 1890 he joined the staff of the Yale Observatory, and in the following year was appointed assistant astronomer, a position he held until 1911. From 1910 to 1913 he served as acting director of the observatory. His published works include "Heliumeter Triangulation of the Victoria Comparison Stars," in *Annals of the Cape Observatory* (1897); and the following papers in *Transactions of Yale University Observatory*: "Triangulation of the Principal Stars of the Cluster in Coma Berenices" (vol. 1, part 5, 1896); "Parallax Investigations on 163 Stars, Mainly of Large Proper Motion" (vol. 2, part 1, 1906); "Parallax Investigations on 35 Selected Stars" (vol. 2, part 2, 1910); "Catalogue of Yale Parallax Results" (vol. 2, part 4, 1912); and "Parallax of 41 Southern Stars" (vol. 2, part 3, 1912).

CHASE, George, American law professor: b. Portland, Me., Dec. 29, 1849; d. New York, N. Y., Jan. 8, 1924. He was graduated from Yale University in 1870 and from Columbia Law School in 1873. In the same year he was admitted to the New York bar, but never practiced. From 1873 to 1878 he was instructor and then assistant professor of municipal law, and from 1878 to 1891 professor of criminal law, torts, and procedure, at Columbia Law School. Disapproving the adoption of the case system of teaching law, he resigned from the Columbia faculty in 1891 and became dean of the New York Law School, which had been chartered through his efforts, and remained in this post until his death. His published works include *The American Student's Blackstone* (1876-1877); *Leading Cases Upon the Law of Torts* (1892); *Leading Cases Upon the Law of Wills* (1892); and *The Code of Civil Procedure of the State of New York as Amended* (1909-1920).

CHASE, Harry Woodburn, American educator: b. Groveland, Mass., April 11, 1883. He received his B.A. (1904) and M.A. (1908) degrees from Dartmouth College, and his Ph.D. (1910) from Clark University. In 1909-1910 he directed a clinic for subnormal children at Clark University, and then became professor of psychology at the University of North Carolina, a post he retained until 1918, when he was appointed acting dean of the college of liberal arts. From 1919 to 1930 he served as president of the university, and from 1930 to 1933 as president of the University of Illinois. Appointed chancellor of New York University in 1933, he remained in this position until his retirement in 1951. During his tenure as chancellor notable advances were made in many fields, and particularly in law and medicine.

CHASE, Mary Coyle, American playwright: b. Denver, Colo., Feb. 25, 1907. After attending

the University of Denver (1921-1923) and the University of Colorado (1923-1924), Mary Coyle became a reporter. In 1928 she married Robert Lamont Chase, by whom she had three children. From 1928 to 1931 she was a reporter for the *Rocky Mountain News* in Denver, and from 1932 to 1936 a free-lance correspondent of the International News Service and the United Press. Soon thereafter she began to write plays, including *Now You've Done It* (1937) and *Too Much Business* (1938). Her first success came in 1944, with the New York production of *Harvey*, for which she received the Pulitzer Prize in 1945. Her gift for fantasy was exhibited again in 1952, with the production of *Mrs. McThing*. Later that year a comedy, *Bernardine*, was also presented in New York.

CHASE, Mary Ellen, American educator and writer: b. Blue Hill, Me., Feb. 24, 1887. She received her B.A. degree from the University of Maine in 1909, and her M.A. (1918) and Ph.D. (1922) degrees from the University of Minnesota. After serving as instructor (1918-1922) and assistant professor (1922-1926) of English at the University of Minnesota, she joined the faculty of Smith College as associate professor of English literature, attaining full professorship in 1929. In addition to many essays and books on writing, her published works include *Uplands* (1927); *A Goodly Heritage* (autobiographical novel, 1932); *Mary Peters* (her best-known novel, 1934); *Silas Crockett* (1935); *This England* (1936); *Dawn in Lyonesse* (1938); *A Goodly Fellowship* (1939); *Windswept* (1941); *The Bible and the Common Reader* (1944); *Jonathan Fisher* (biography, 1948); *The Plum Tree* (1949); *Abby Aldrich Rockefeller* (biography, 1950); and *Readings from the Bible* (1952); *Recipe for a Magic Childhood* (1952).

CHASE, Philander, American Episcopal clergyman: b. Cornish, N. H., Dec. 14, 1775; d. Jubilee College, Ill., Sept. 20, 1852. He was graduated from Dartmouth College in 1796, and was ordained deacon (1798) and priest (1799) of the Protestant Episcopal Church. After holding several missionary charges in northern New York, he moved to New Orleans in 1805 and then to Hartford, Conn., in 1811. In 1817 he went to Ohio, where he organized a number of parishes; two years later he was consecrated first bishop of Ohio. He served as president of Cincinnati College in 1821-1822, and then made plans for the establishment of a theological seminary. To raise funds for it, he went to England, where, through the influence of the 1st Baron Gambier and the 2d Baron Kenyon, he obtained \$30,000, with which, in 1824, he founded Kenyon College at Gambier, Ohio. Chase served as president of the college until 1831, when he resigned this office as well as his bishopric. In 1835 he was elected bishop of Illinois. Visiting England once more, he raised \$10,000, with which he founded (1839) Jubilee College, Peoria County, Ill. (The main building of the college is preserved in Jubilee College State Park.) In 1843, on the death of Bishop Alexander Viets Griswold (q.v.), Chase became presiding bishop of the church. His published works include *Star in the West or Kenyon College* (1828); *Defence of Kenyon College* (1831); *A Plea for Jubilee* (1835); and *Reminiscences of Bishop Chase, an Autobiography* (2 vols., 1848).

CHASE, Pliny Earle, American scientist: b. Worcester, Mass., Aug. 18, 1820; d. Haverford, Pa., Dec. 17, 1886. He was graduated from Harvard College in 1839 and became a teacher, serving as principal of district schools in Leicester and Worcester, Mass., until 1841, when he went to Philadelphia. After teaching there for seven years, he was engaged in the stove and foundry business until 1861, when he resumed his profession. Meanwhile he employed his leisure in scientific studies, and in 1864 received the Magellanic Medal of the American Philosophical Society for his paper, "Numerical Relations Between Gravity and Magnetism." The results of further research in mathematics and physics were published subsequently in over 120 articles in *Proceedings of the American Philosophical Society*; he also wrote *Elements of Meteorology for Schools and Households* (1884). In 1871 he became professor of natural sciences, and in 1875 professor of philosophy, at Haverford College.

CHASE, Salmon Portland, American lawyer and statesman: b. Cornish, N. H., Jan. 13, 1808; d. New York, N. Y., May 7, 1873. His father, Ithamar Chase, died when he was nine years old, and soon thereafter he was placed under the care of his uncle, Philander Chase (q.v.), Episcopal bishop of Ohio, and attended the bishop's school at Worthington, near Columbus. He entered Cincinnati College, of which his uncle was president, in 1821, but remained there less than a year before he returned to New Hampshire. After some preparatory study he entered Dartmouth College as a junior, being graduated in 1826. He then went to Washington, D.C., where he conducted a boys' school for three years. In Washington he made the acquaintance of William Wirt (q.v.), under whose nominal supervision he studied law. Admitted to the bar in 1829, he began to practice in Cincinnati in the following year and soon became known as one of the best lawyers in the city. In 1832 he formed the project of compiling a collection of the laws of Ohio with notes and references. Published as *Statutes of Ohio* (3 vols., 1833-1835), it became the standard edition and gave Chase a solid reputation throughout the Middle West. Early in his career he became identified with the antislavery movement, but he indignantly disavowed any sympathy with the sentiments of William Lloyd Garrison (q.v.), declaring that he was not one of those "abolitionists or antislavery men who regarded the Constitution as at war with moral obligations and the supreme law." He states in his diary that he differed with Garrison and others "as to the means by which the slave power could be best overthrown and slavery most safely and fitly abolished under our American Constitution." He was a frequent speaker at antislavery meetings and conventions in Ohio and other states, but he was neither an orator nor a good stump speaker. His forte was the preparation of formal addresses and platforms, in which he had time and space to marshal his facts and thoughts, and he was often called on to undertake such tasks for the Liberty and Free-Soil parties. While these abilities made Chase a valuable ally of the Ohio antislavery men, he became their leader chiefly through his pronouncements against slavery and his legal services in connection with fugitive slave cases. He became known as the "attorney general for runaway Negroes," but was defeated in

every case in which he appeared for the defense. Some of his arguments were against historical facts, as when he denied that Congress had power to establish slavery anywhere by any process. He admitted that laws had been framed to support slavery in the District of Columbia, in the territories, and, insofar as fugitive slaves were concerned, in the free states, but he held that Congress had no constitutional power to enact such laws. In March 1837, he acted as counsel for Matilda, an alleged fugitive slave, and for James G. Birney, accused of harboring her. Chase based his argument on the fact that Matilda had been brought into Ohio by her master and had escaped, and so was a free person and could not be "a person held to service or labor in one State, under the laws thereof, escaping into another." The case was decided against Chase, and Matilda was remanded into slavery, but Birney appealed and the state supreme court reversed the decision.

In 1840, Chase, a former Whig, joined the new Liberty Party. Within a year he was practically the leader of the party in Ohio, and for eight years he organized conventions, prepared party addresses, and bolstered the antislavery press. He presided over the convention of its successor, the Free-Soil Party, in Buffalo in 1848. In 1849, through a combination of Democrats and Free-Soilers in the state legislature, he was elected to the United States Senate. There he continued his opposition to slavery during the period of the Compromise of 1850, and was particularly outspoken in condemning the position of Henry Clay. He usually acted with the Democrats, since he claimed to have been elected as a Democrat, and thereby lost much of the confidence of the Free-Soilers. He gradually became estranged from the Democrats, however, and the nomination of Franklin Pierce for the presidency in 1852 on a platform pledged to support the Compromise of 1850 forced Chase to withdraw entirely from the Democratic Party and rejoin his old Free-Soil allies. In 1854 he became a leader of the opposition in the Senate to the Kansas-Nebraska Bill, issuing his celebrated "Appeal of the Independent Democrats in Congress to the People of the United States." With the dissolution of the Whig Party, Chase did much to further the formation by northern Whigs and independent Democrats of the Republican Party, and in 1855 the new party (then known as an anti-Nebraska party) nominated him for the governorship of Ohio. Elected after a close contest, he introduced a number of needed reforms in state administration and continued his efforts on behalf of the Negroes. In 1856 he was an unsuccessful candidate for the Republican presidential nomination, and in the following year was re-elected governor. In February 1860, he was re-elected to the Senate for the term beginning in 1861. Again in 1860 he endeavored to obtain the presidential nomination, but received only 49 votes on the first ballot, and his supporters later threw their votes to Abraham Lincoln. In January 1861, Lincoln, then president-elect, invited Chase to become secretary of the treasury. Relinquishing the senatorship, he accepted and took office in March.

Hardly had Chase become secretary when, in April 1861, the Civil War began. He rehabilitated the Treasury; suggested and secured the enactment of new taxes and property confiscation acts; borrowed money; provided the legal-tender

paper currency authorized by Congress; proposed a national banking system and saw it put into operation (1863); and in general administered his department and the financial affairs of the country in a creditable manner. Despite his heavy duties, however, he never lost sight of the slavery question. He opposed Lincoln's colonization project, but warmly supported the Emancipation Proclamation. Chase differed with the president in many of his political views, and he felt aggrieved when Lincoln disregarded his advice on military affairs. He corresponded with military officers, and often expressed distrust of the president's conduct of affairs. He had hoped to obtain ascendancy over Lincoln, and when he learned that Lincoln completely controlled the situation and was determined to abide by his own policies, he resigned, on Dec. 20, 1862, stating that he expected his opinions and those of his colleagues in the cabinet to carry more weight with the president: "There are certain heads of departments, but no real Cabinet." Lincoln refused to accept the resignation, but on March 3, 1863, Chase prepared another resignation because the president had refused to nominate a revenue collector selected by the secretary. Again, on May 11, 1863, Chase became disgruntled because Lincoln had removed an official whom the president considered unfit for his post, but the proffered resignation was refused. The minor differences between Lincoln and Chase were accentuated by their rivalry for the presidential nomination in 1864. The issuance in February 1864 of the Pomeroy Circular, criticizing Lincoln, rendered Chase's nomination impossible and placed him in a delicate relationship with the president, and on February 22, he again offered to resign and again was requested to remain. Finally, in June 1864, another dispute arose over patronage and, although it was settled peaceably, Chase decided once more to resign, on June 29. On the following day, Lincoln unexpectedly accepted the resignation, appointing William P. Fessenden as Chase's successor.

Before his retirement from the cabinet Chase had signified a desire to be chief justice of the United States, and on Dec. 6, 1864, Lincoln nominated him to fill the post made vacant by the death of Roger B. Taney. Chase took little part in President Andrew Johnson's dispute with Congress regarding reconstruction, but he privately opposed the readmission of any seceded state until it had granted suffrage to Negroes. He drafted the 14th Amendment, and later used it in his dissent from the court's decision in the *Slaughterhouse Cases* (q.v.). He considered the president's military governments abnormal, and even after Johnson's proclamation declaring the war at an end (April 2, 1866) he steadfastly refused to hold court in Virginia and North Carolina (which were included in his circuit) "until all possibility of claim that the judicial is subordinate to the military power is removed by express declaration from the President." In June 1867, however, he assumed his functions in Raleigh. Chase dissented from the court's decision in the *Milligan* (see *MILLIGAN, EX PARTE*), *Cummings*, and *Garland* cases. He refused at first to sit in the trial of Jefferson Davis, and was relieved when the case was terminated by the amnesty proclamation of Dec. 25, 1868. Though considering the trial impolitic and unjust, Chase presided with calmness and good judgment over the impeachment of President

Johnson. Meanwhile, he had permitted his name to be brought before the Republicans as a presidential candidate, but soon became convinced that he could not secure the nomination and a few weeks later endeavored to become the Democratic nominee. Failing once more in his persistent ambition, he continued his work on the bench. Among the important decisions he wrote was that in the case of *Texas v. White*, in which he expounded the nature of government as "an indestructible Union, composed of indestructible States," reversing his previous theory of state suicide and, as he did also in the case of *White v. Hart*, approving the method of reconstruction that had been adopted. He wrote the court's decision in the case of *Hepburn v. Griswold*, reviewing judicially and construing the statutes which as secretary of the treasury he himself had set in motion only a few years before. The court decided that the Legal Tender Act of 1862 was unconstitutional insofar as it compelled the acceptance of legal-tender paper currency in payment of debts contracted before the statute had been enacted. By subsequent decisions in the Legal-Tender Cases (q.v.), however, Chase was reversed, the court holding the act constitutional.

In August 1870, Chase had a paralytic stroke, but he gradually recovered and, though absent from the court during the term of 1870-1871, sat during the terms of 1871-1872 and 1872-1873, preparing numerous opinions. He was well enough in 1872 to aspire to the presidential nomination once more, but in 1873 his health failed rapidly and he lived only a day after a second stroke.

Consult Hart, A. B., *Salmon Portland Chase* (Boston 1899); Smith, D. V., *Chase and Civil War Politics* (Columbus 1931); Hendrick, B. J., *Lincoln's War Cabinet* (Boston 1946); Donald, David, ed., *Inside Lincoln's Cabinet: The Civil War Diaries of Salmon P. Chase* (New York 1954).

CHASE, Samuel, American jurist and Revolutionary leader: b. Somerset County, Md., April 17, 1741; d. June 19, 1811. He was educated by his father, the Rev. Thomas Clark, who instructed him in the classics, and from 1759 to 1761 studied law at Annapolis, being admitted to the bar at the age of 20. As a member of the Maryland General Assembly (1764-1784), he distinguished himself by his opposition to the royal governor. He took the lead in denouncing and resisting the Stamp Act, and in 1774 became a member of the Maryland Committee of Correspondence and was chosen as a delegate to the 1st Continental Congress. He served in subsequent congresses until 1778, and again in 1784 and 1785. That of 1776 sent him with Benjamin Franklin and Charles Carroll of Carrollton on a mission to Canada. Chase signed the Declaration of Independence without hesitation, and was active on numerous committees until 1778, when his attempt to obtain a corner on flour through information he had received as a member of Congress was attacked by Alexander Hamilton and resulted in Chase's political eclipse until 1783. In that year the governor of Maryland sent him to London to recover Maryland's stock in the Bank of England, but he accomplished little and the matter was not settled for many years. In 1788, Chase was appointed chief judge of the criminal court, and in 1791 chief judge of the general court. Although he opposed the adoption of the Constitution, he later became a Fed-

eralist. In 1796, George Washington appointed him to the Supreme Court, where he delivered a number of notable opinions, including that in the case of *Ware v. Hylton*, in which he asserted the supremacy of national treaties over state laws. In 1804, however, his conduct as a circuit judge in 1800 and 1803 resulted in his impeachment by the House of Representatives. In his trial before the Senate in the following year he defended himself ably, and was acquitted.

CHASE, Stuart, American writer: b. Somersworth, N. H., March 8, 1888. He was educated at the Massachusetts Institute of Technology and at Harvard University, from which he was graduated in 1910. He then practiced as a certified public accountant in Boston until 1917, when he was employed by the Federal Trade Commission as an investigator. In 1922 he became associated with the Labor Bureau, Inc., a connection he maintained until 1939. His published works, in addition to many articles, include *The Tragedy of Waste* (1925); *Men and Machines* (1929); *A New Deal* (1932); *The Economy of Abundance* (1934); *Rich Land, Poor Land* (1936); *The Tyranny of Words* (1938); *The New Western Front* (1939); *Idle Money, Idle Men* (1940); *Men at Work* (with his wife, Marian Tyler, 1945); *Tomorrow's Trade* (1945); *The Proper Study of Mankind* (1948); *Roads to Agreement* (with Marian Tyler, 1951); and *Power of Words* (1954).

CHASE, William Merritt, American painter: b. Williamsburg, Ind., Nov. 1, 1849; d. New York, N. Y., Oct. 25, 1916. He studied art at the National Academy of Design in New York from 1869 to 1871. In the following year he went to Europe and continued his studies at Munich and Venice for five years. In 1878 he opened a studio in New York, where he spent most of his time thereafter, teaching at the Art Students' League and exhibiting at the National Academy, of which he became a member in 1890. Among his paintings, which include portraits, still-life subjects, and landscapes, are a portrait of James Whistler, *Carmencita*, and *The Lady in Black*, all in the Metropolitan Museum of Art, New York; *Ready for the Ride* (1878); *American Fish* (1905); *Portrait of an Artist* (1906); *Studio Interior* (1911); *The Orangery* (1911); and *Portrait of Mrs. H.* (1912).

CHASE CITY, town, Virginia, situated in Mecklenburg County, 28 miles east-northeast of South Boston. It has freight service via the Southern Railway. There are tobacco warehouses and establishments manufacturing wood products, clothing, and shoes, and processing food. The town was incorporated in 1873. Pop. (1950) 2,519.

CHASE NATIONAL BANK OF THE CITY OF NEW YORK, The. One of the largest and most important commercial banks in the United States, the Chase had deposits of \$5,174,415,072 and total assets of \$5,678,726,512 as of June 30, 1954.

The Chase National Bank was organized by John Thompson on Sept. 12, 1877, and opened for business at 177 Broadway, New York. The original capital stock of the bank, \$300,000, was owned by five of its organizers. On June 30, 1954, the capital funds of the bank amounted to

\$390,299,391, consisting of capital of \$111,000,000, surplus of \$219,000,000, and undivided profits of \$60,299,391. The 7,400,000 shares of stock were owned by about 78,000 shareholders.

Col. Samuel C. Thompson, son of the founder, was the first president. On his death in 1884 he was succeeded by his father. Between 1886 and 1911 the bank was headed consecutively by two former United States comptrollers of the currency, Henry W. Cannon and A. Barton Hepburn. Albert H. Wiggin served as president from 1911 to 1918, and as chairman of the board of directors from 1918 to 1930. Winthrop W. Aldrich, former president of the Equitable Trust Company, became president in 1930 and chairman of the board in 1934. He was succeeded in the presidency by H. Donald Campbell, who retired in 1946, at which time Arthur W. McCain was elected president. In 1949, Percy J. Ebbott was elected president. Winthrop W. Aldrich retired as chairman of the board in 1953, and was succeeded by John J. McCloy.

In 1921 the Chase enlarged its resources for the first time by consolidation with another bank. Merging with the Metropolitan National Bank, it acquired the nucleus of its branch system by taking over seven metropolitan branches in New York. In 1925 the first of its foreign branches were obtained: Havana, Cristobal, and Panama. Thereafter the following banks were merged with the Chase: Mechanics and Metals National Bank (1926); Mutual Bank (1927); Garfield National Bank and National Park Bank (1929); Equitable Trust Company and Interstate Trust Company (1930); and American Express Bank and Trust Company (1931). The Chase in 1953 had 28 branches in New York and 17 branches abroad: 2 in London; 1 each in Paris and Frankfurt am Main; 2 in Japan; 4 in Cuba; 2 in Puerto Rico; and 1 each in Panama, Colón, David, Cristobal, and Balboa. Safe deposit vaults are maintained in New York offices and in Paris. The Chase National Executors and Trustees Corporation, Ltd., London, is an affiliate. Offices of representatives are located in Mexico City, Buenos Aires, Rome, Beirut, and Bombay.

The Chase National Bank is one of the principal New York depositaries for banks of the United States and other countries. It serves as New York correspondent for some 3,800 United States banks, or more than half the nation's banks which utilize New York correspondent facilities. Every type of banking service is offered by the Chase through its commercial, foreign, and trust departments. Included in the last named are personal, corporate, agency, and pension trust services. The Chase also provides such popular services for individuals as installment loans, savings accounts in its compound interest department, and no-balance checking accounts.

The Chase had an outstanding record in assisting the United States government to raise funds through the sale of war loan securities during World War II. More than \$28.8 billion in war and victory bonds were sold by the bank and members of its staff—a sum representing 5.3 per cent of all the bonds sold during eight nationwide campaigns.

CRAWFORD WHEELER, Vice President, The Chase National Bank of the City of New York.

CHASING, the art of indenting designs on metals. Figures on metal are often produced in

relief by being punched out from behind and sculptured or finished in front with small chisels and gravers. It is the latter process that is properly called chasing, and the same term is applied to designs produced by hand tools on more or less flat surfaces. The process is a very old one and is seen on ancient Egyptian, Assyrian, and Greek works of art.

CHASKA, chās'ká, city, Minnesota, seat of Carver County, situated at an altitude of 725 feet, on the Minnesota River, 20 miles southwest of Minneapolis. It is served by the Chicago, Milwaukee, St. Paul and Pacific and the Minneapolis & St. Louis railroads. The city serves as a center for the surrounding farming region and has plants producing beet sugar, dairy products, canned vegetables, and bricks. There are three prehistoric Indian mounds in the city park. First settled in 1853, Chaska was incorporated as a village in 1871 and as a city in 1891. Pop. (1950) 2,008.

CHASLES, shāl, Michel, French mathematician: b. Épernon, France, Nov. 15, 1793; d. Paris, Dec. 18, 1880. While a student at the École Polytechnique in 1814, he took part in the defense of Paris. After his graduation in the following year he retired to Chartres, where he devoted himself to mathematical studies. In 1829 he addressed to the Brussels Academy a memoir on two general principles of geometry, duality and homography. The introduction to this memoir was expanded into *Aperçu historique sur l'origine et le développement des méthodes en géométrie* (1837). In 1841, Chasles was appointed professor of geodesy and applied mechanics at the École Polytechnique, and in 1846 professor of advanced geometry at the Sorbonne. In 1851 he became a member of the Académie des Sciences. Chasles contributed much to projective geometry. His published works include *Traité de géométrie supérieure* (1852); *Trois livres de géométrie d'Euclide* (1863); *Traité des sections coniques* (1865); and *Rapport sur les progrès de la géométrie* (1874).

CHASLES, (Victor Euphémon) Philarète, French scholar and writer: b. Mainvilliers, France, Oct. 8, 1798; d. Venice, Italy, July 18, 1873. The son of a Jacobin, Pierre Jacques Michel Chasles, he was educated according to the principles of Jean Jacques Rousseau's *Émile*. From 1817 to 1823 he lived in England and later traveled widely in other European countries, whose literatures he studied and interpreted for French readers. In 1837 he was appointed curator of the Bibliothèque Mazarine, and in 1841 professor of Continental languages and literatures at the Collège de France. His published works include *Tableau de la marche et du progrès de la langue et de la littérature françaises depuis le commencement du XVI^e siècle jusqu'en 1610* (1828); *Oliver Cromwell* (1847); *L'antiquité* (1847); *Le seizième siècle en France* (1848); *Galileo Galilei* (1862); *Esquisses* (1846-1864); *Les voyages d'un critique à travers la vie et le livre* (1866-1868); *L'Artin, sa vie et ses écrits* (1873); and *Mémoires* (1877).

CHASSAIGNAC, shā-sē-nyák', Pierre Marie Édouard, French surgeon: b. Nantes, France, 1804; d. Versailles, Aug. 26, 1879. He studied medicine in Nantes and went to Paris,

where he became a professor at the university and a member of the Académie de Médecine. His contributions to surgery include the invention of the instrument known as the linear écraseur and the introduction (1859) of drainage by rubber tubes. He was one of the first to dress wounds by complete occlusion. Chassaignac's tubercle is named for him. His published works include *Études d'anatomie et de pathologie chirurgicale* (2 vols., 1851); *Traité de l'écrasement linéaire* (1856); *Traité pratique de la suppuration et du drainage chirurgical* (2 vols., 1859); and *Traité clinique et pratique des opérations chirurgicales* (2 vols., 1861-1862).

CHASSE, shā-sā', BARON David Hendrik, Dutch general: b. Tiel, Netherlands, March 18, 1765; d. Breda, May 2, 1849. Trained as a soldier from his early youth, he entered French service in 1787, and by 1793 had risen to the rank of lieutenant colonel. He fought in the Netherlands under Gen. Charles Pichegru in 1795, and subsequently distinguished himself with French armies in Germany and, from 1808 to 1813, in Spain. Because of his fondness for bayonet charges, Napoleon nicknamed him General Baionette. In 1809 he was made a baron by Louis Bonaparte, who was then king of Holland. Chassé fought as a general of division in the defense of France in 1814, but after the abdication of Napoleon in April he joined the Dutch Army. As lieutenant general of the Dutch forces at Waterloo in 1815, he did good service against his former comrades, the French. He defended the citadel of Antwerp against the Belgians in 1830, and against the French in 1832. On the latter occasion he was forced to surrender after a three weeks' siege. Made a prisoner of war by the French, he was released in May 1833 and retired to private life.

CHASSELOUP-LAUBAT, shās-lōō' lō-bā', François de, French soldier and military engineer: b. St.-Sernin, Charente-Maritime, France, Aug. 18, 1754; d. Paris, Oct. 10, 1833. He entered the army in 1774 and by 1791 had risen to the rank of captain. In 1797 he distinguished himself at the siege of Mantua, and two years later was made chief of engineers in Italy. He was in charge of fortifications at the siege of Danzig in 1807, and retired from the army in 1812. He was made a peer by Louis XVIII.

His son, JUSTIN PROSPER CHASSELOUP-LAUBAT (b. Alessandria, Italy, March 29, 1805; d. Versailles, France, March 29, 1873), served as minister of marine in 1851 and from 1859 to 1867. He was president of the Conseil d'État in 1869 and a member of the National Assembly in 1871.

CHASSEPOT, shās-pō', a breech-loading rifle named for its inventor, Antoine Alphonse Chassepot (1833-1905), which was adopted for use in the French Army in 1866, after the value of the Prussian needle gun had been shown in the Austro-Prussian War. Considerably lighter than the needle gun, it proved a much better weapon in the Franco-Prussian War, but was replaced by another type in 1874 and was little used thereafter. It was a bolt-action gun with an effective range of 1,500 paces, but its lightness (it weighed 9 pounds, 5 ounces) and its large charge produced a great recoil, and the barrel heated so that the weapon could hardly be handled.

CHASSERIAU, shā-sā-ryō', **Théodore**, French painter: b. Samaná, Dominican Republic, Sept. 20, 1819; d. Paris, France, Oct. 8, 1856. He was greatly influenced by Jean Auguste Dominique Ingres, under whom he studied in Rome, but later became primarily a colorist. In addition to murals in the Église St.-Merri (1843), the Église St.-Roch (1854), and those he painted for the Cours des Comptes in the Palais d'Orsay (fragments which survived the burning of the palace in 1871 are preserved in the Louvre), Chassériau's works include *Cain maudit* (1836); *Retour de l'enfant prodigue* (1836); *Suzanne au bain* (1839); *Vénus Anadyomène* (1839); *Le Christ au jardin des oliviers* (1839); *Andromède attachée au rocher par les Néréides* (1841); *Esther se parant pour être présentée à Assuérus* (1842); *Captives troyennes* (1842); and *Portrait équestre d'Ali-ben-Hamet, calife de Constantine*.

CHASSEUR, shā-sūr', a word of French origin, meaning "hunter," applied to a member of a body of special light infantry or cavalry troops in France and, formerly, in other European countries. Chasseurs were first organized in 1743 and were widely used in the late 18th and 19th centuries and, to some extent, in World War I, but they declined in importance with the introduction of mechanized warfare. In the post-World War II French Army there were only a few battalions of Chasseurs Alpins (light mountain troops) and a single squadron of Chasseurs d'Afrique.

CHASTELARD, shā-tlār', **Pierre de Boscobel de**, French poet: b. Dauphiné, France, 1540; d. Edinburgh, Scotland, 1563. A grandson of the seigneur de Bayard (q.v.), he fell in love with Mary Stuart at the court of Francis II, to whom she was then married, and expressed his admiration for her in innumerable poems. When, in 1561, following the death of her husband, she returned to Scotland, Chastelard was one of her escort. Obligated to return to France after this duty was performed, he went to Scotland once more in 1562. Mary gave him a gracious welcome, and he accompanied the court to Burntisland Castle. There he continued to press his suit in an increasingly indiscreet manner. Finally, in 1563, he was brought to trial at St. Andrews and hanged.

CHASTELARD, a tragedy published in 1865 by Algernon Charles Swinburne (q.v.). Written in 1862 and dedicated to Victor Hugo, it was inspired by the tragic death of Pierre de Boscobel de Chastelard (q.v.). In the play, Mary Beaton, who loves Chastelard herself, admits him to Mary Stuart's chamber, where he convinces the queen of his love for her. She, not wishing the love known, orders his death. Although the play has many beautiful lines, it lacks action and is meant to be read rather than performed on the stage.

CHASTELLAIN or **CHASTELAIN**, shā-tlān', **Georges**, Flemish chronicler and poet: b. Aalst, Flanders, 1404; d. Valenciennes, France, March 20, 1475. He was a soldier in the army of Philip the Good, duke of Burgundy, until 1435, when the duke made peace with France. For 10 years Chastellain engaged in diplomatic missions in France and then returned to the service of the duke, first as a diplomat and then, from 1455, as

historiographer. His great work, the *Chronique des ducs de Bourgogne*, covers the history of the house of Burgundy from 1419 to 1474. Among his other works are *Epistre au bon duc Philippe de Bourgogne*; *Souhaits au duc Charles de Bourgogne*; *Dit de vérité*, in which he criticized Charles VII of France; and *Princes*, which contains a satire of Louis XI.

CHASTELLUX, shā-tlū', **MARQUIS François Jean de**, French soldier: b. Paris, France, 1734; d. there, Oct. 28, 1788. He entered the army in 1749, distinguishing himself as a colonel in the Seven Years' War, and served in the American Revolution as a major general under the comte de Rochambeau. His experiences in the United States, where he gained the friendship of George Washington, led him to publish several books, including *Voyages dans l'Amérique septentrionale dans les années 1780, 1781 & 1782* (2 vols., 1786); and *Discours sur les avantages et les désavantages qui résultent pour l'Europe de la découverte de l'Amérique* (1787). He became a member of the French Academy in 1775.

Consult Sincoe, J. G., *Remarks on the Travels of the Marquis de Chastellux* (New York 1931).

CHASUBLE, chāz'ū-b'l or chās'ū-b'l, the outermost vestment worn by a priest of the Roman Catholic Church in celebrating the Mass. In its original form it was circular or elliptical and resembled a poncho, with an opening for the head in the center. The modern form consists of a more or less oval front and back joined at the top, where there is an opening for the head to pass through. The garment is usually of silk embroidered and decorated with gold or silver thread and with a cross on the back. See also **COSTUME, ECCLESIASTICAL—Vestments of the Roman Church**.

CHAT, the common name of a number of birds. In the United States it is applied to two warblers, the yellow-breasted chat (*Icteria virens*), which is olive green on top and white underneath and is found in the eastern part of the country; and the long-tailed chat (*Icteria virens longicauda*), duller in color, which is found in the West from British Columbia southward to Mexico. (See also **WARBLERS**.) In Great Britain the name is applied to a number of birds of the genera *Saxicola* and *Pratincola*, including the wheatear, stonechat, and whinchat.

CHATARD, Francis Silas, American Roman Catholic prelate: b. Baltimore, Md., Dec. 13, 1834; d. Indianapolis, Ind., Sept. 7, 1918. After being graduated from Mount St. Mary's College, Emmitsburg, Md., in 1853, he studied medicine at the University of Maryland, from which he received his M.D. degree in 1856. He practiced for only two years before going to Rome to study for the priesthood at the Urban College of the Propaganda. Ordained in 1862, he was appointed vice rector of the American College in Rome in the following year, and promoted to the rectorship in 1868. Subsequently he became papa chamberlain to Pope Pius IX. In 1878 he was consecrated bishop of Vincennes, Ind. (the title of the diocese was changed from Vincennes to Indianapolis in 1898). From 1905 he was assisted by a bishop coadjutor, Joseph Chartrand. During Bishop Chatard's tenure a new cathedral, a hospital, and a number of schools were built in

Indianapolis. He was much interested in education, and he translated a number of works from the French.

CHATEAU. See CASTLES AND CHATEAUX.

CHATEAU-THIERRY, shā-tō' tyē-rē', town, France, situated in the Department of Aisne, on the right bank of the Marne River, 37 miles south-southwest of Laon. It occupies the side of a hill, whose summit is crowned by the ruins of the old castle of Thierry, said to have been built by Charles Martel. The house in which Jean de La Fontaine was born in 1621 is preserved as a museum. The town has an active trade in champagne wines and manufactures musical instruments, agricultural tools, and woolen yarn. Stone is quarried nearby.

Château-Thierry has an ancient military history. It was captured by the English in 1421, and by Charles V in 1544. Several battles were fought in the town in 1814, and in 1870 it was occupied by the Germans. In 1918, at nearby Belleau Wood, American troops won their first successes against the Germans (see WAR, EUROPEAN—*Military Operations on the Western Front*), and there is an American military cemetery there. The town was badly damaged during the war, and it sustained further damage in World War II. Pop. (1946) 7,283.

CHATEAUBRIAND, shā-tō-brē-ān', VICOMTE (François) René de, French writer and statesman: b. St.-Malo, France, Sept. 4, 1768; d. Paris, July 4, 1848. A member of an ancient aristocratic family, he entered the army in 1786. At the outbreak of the French Revolution he went to Paris to witness the great events taking place there. On the pretext of exploring to discover the Northwest Passage, he went to the United States in April 1791. There he confined his travels mainly to the eastern part of the country and met George Washington in Philadelphia. Out of his American experiences he later (1826) published *Les Natchez* (see NATCHEZ, LES).

Returning to France in January 1792, he married Céleste Buisson de Lavigne. Soon thereafter he joined other émigrés in the Prussian Army on the Rhine. Wounded at Thionville in September 1792, he went to London, where, impoverished and in poor health, he led at first a miserable existence. Eventually he was able to earn a living by giving French lessons and making translations for the booksellers. In 1797 he published *Essai historique, politique et moral sur les révolutions anciennes et modernes, considérées dans leurs rapports avec la Révolution française*, which had little success in England and attracted no notice in France. The essay is pervaded by a strong skepticism toward religion, but Chateaubriand's views on this subject soon underwent a sudden and important change. The death of his mother in prison, and the account of her last moments sent him by his sister, who had died herself by the time her letter reached her brother, made a lasting impression on Chateaubriand. Thereafter he became a firm believer in Christianity.

In 1800 he ventured to return to France. Encouraged by the success of an essay on literature which he had contributed to the *Mercure de France*, he published in 1801 his *Atala* (q.v.). With another romance, *René*, it was introduced as an episode into his celebrated work, *Génie du*

Christianisme, which appeared in the following year. This work may be said to have caused a religious revival, and it inaugurated a new period in the social history of France. Chateaubriand's object was to demonstrate the superiority of Christianity over all other religions from a poetic and artistic, as well as a moral, point of view. Though more brilliant than profound, the *Génie du Christianisme* is unsurpassed for beauty of language and description and for the eloquence of its impassioned appeal. Its main charm lies in its imagery, which is drawn from nature, and especially from nature as exemplified in the scenery of the New World. In this respect, Chateaubriand may be said to have revived in French literature the description of nature. (See also GENIUS OF CHRISTIANITY, THE.)

Chateaubriand's work attracted the attention and admiration of Napoleon Bonaparte, and in 1803 he was appointed French minister to the Republic of Valais, but he resigned in 1804 after the execution of the duc d'Enghien. Going into exile once more, he traveled extensively in Greece, Turkey, Palestine, North Africa, and Spain. In order to give tangible form to the theories which he had propounded in the *Génie du Christianisme*, he began to write *Les Martyrs*, his travels in the Middle East enabling him to describe accurately the scenes amid which part of the epic is laid. Published in 1809, it is considered by some critics to be his best work. Some of the descriptions, such as those of the ancient forests of Gaul, the assemblies of Christians in the catacombs, and the picture of Rome under the emperors, are extremely beautiful. His account of his travels was published in 1811 under the title *Itinéraire de Paris à Jérusalem*.

He greeted the restoration of Louis XVIII with enthusiasm, and his pamphlet, *De Bonaparte et des Bourbons* (1814), was said by the king to have been worth an army of 100,000 men. In 1815, Chateaubriand was made a peer of France. He served as ambassador to Prussia in 1821, and to Great Britain in 1822, and later that year represented France at the Congress of Verona. Appointed minister of foreign affairs in 1823, he was summarily dismissed in the following year at the instance of Comte Jean Baptiste de Villèle. Indignant at this treatment, Chateaubriand attacked the government in the *Journal des Débats*. In 1826 he published *Les aventures du dernier des Abencérages*, a short novel with a Moorish theme. Appointed ambassador to Rome in 1828, he resigned in the following year. After the revolution of 1830, he refused to take the oath of allegiance to Louis Philippe, forfeiting his seat in the Chamber of Peers and a pension of 12,000 francs. He held no public offices thereafter, but continued to write, publishing a number of political and historical works. His memoirs were published posthumously, in 1849–1850, under the title *Mémoires d'outre-tombe*.

Chateaubriand was the chief precursor of the romantic movement in France. He drew attention to the literary resources of the Middle Ages and of Christian antiquity, and he induced his generation to break with the waning classical tradition. His style left its mark on poetry, history, and the novel.

C., *Chateaubriand's Natural Scenery* (Baltimore 1946).

CHATEAUBRIANT, shà-tō-brē-ān', town, France, situated in the Department of Loire-Inférieure, 40 miles north-northeast of Nantes. A trading and railroad center, Châteaubriant has tanneries, flour mills, and establishments manufacturing furniture, hosiery, and agricultural implements. The remains of a castle built at various times from the 11th to the 15th century were damaged in World War II. The Château-Neuf (1533-1537), which has been restored, contains a museum and law courts. Pop. (1946) 7,965.

CHATEAUDUN, shā-tō-dún', town, France, situated in the Department of Eure-et-Loir, overlooking the Loir Valley, 28 miles south-southwest of Chartres. Rebuilt after a fire in 1723, it has straight streets terminating in a large square, the Place du 18-Octobre, at one end of which is a promenade with a view of the valley. The castle of the counts of Dunois, built from the 12th to the 16th century, is on a promontory to the west of the town. Among other notable buildings are the 12th century Church of the Madeleine, burned in 1940 and since restored; and the Church of St.-Valérien, erected from the 12th to the 15th century. A trading center for the surrounding cattle-raising region, the town has factories manufacturing telephone and optical equipment, blankets, and machine tools.

Châteaudun has been in existence since the Gallo-Roman period. In the Franco-Prussian War it was captured by the Germans on Oct. 18, 1870, after a heroic defense. It sustained some damage in World War II. Pop. (1946) 7,309.

CHATEAUGAY (in Canada CHÂTEAUGUAY), shāt'-ā-gē (Fr. shā-tō-gā'), river, New York and Canada. About 60 miles long, it rises in Lower Chateaugay, the more northern of the two Chateaugay lakes, and flows north through Franklin County, N. Y., and Châteauguay County, Quebec, into the St. Lawrence River, which it joins at a point opposite Lachine on Montreal Island. It was the scene of important military operations during the War of 1812 (see CHATEAUGUAY, BATTLE OF).

The name is derived from that of a seigneurie on the St. Lawrence River granted in 1673 to Charles Le Moyne, sieur de Longueuil, who in turn derived it from a place name in France.

CHATEAUGAY LAKES, two small lakes, New York. Upper Chateaugay, in Clinton County, is about 4 miles long. Lower Chateaugay, in the eastern part of Franklin County, is about 3 miles long; the Chateaugay River flows out of its northern end.

CHATEAUGUAY, SIEUR DE. See LE MOYNE, ANTOINE.

CHATEAUGUAY, town, Quebec, Canada, situated on Lake St. Louis (an expansion of the St. Lawrence River), near the mouth of the Châteauguay River and about 14 miles southwest of Montreal. It is served by the New York Central Railroad. Châteauguay is a market for the surrounding rich mixed farming and dairying region. Pop. (1951) 2,240.

CHATEAUGUAY, Battle of, an encounter between American and British troops which took place on Oct. 26, 1813, about 15 miles from the mouth of the Châteauguay River, Quebec, Can-

ada, during the War of 1812. The engagement, with that of Chrysler's Field (see CHRYSLER'S FIELD, BATTLE OF), was a turning point in the American invasion of Lower Canada. The general plan of the invasion was that of a converging movement of two forces on Montreal, which was protected by an army of 15,000 regulars under Sir George Prevost with strong natural and subsidiary river defenses. One of the forces, under Gen. Wade Hampton, was to strike northward from Burlington, Vt., while the other and larger, under Gen. James Wilkinson, was to descend the St. Lawrence from Sackets Harbor on Lake Ontario, the two to effect a junction at or near the mouth of the Châteauguay. Both men were under direct instructions from Secretary of War John Armstrong, the question of precedence in command between the two being left in abeyance. Hampton, thus instructed, crossed the international boundary on September 20, but, encountering opposition and difficulties in water supply, turned westward 25 miles to the settlement of Chateaugay Four Corners, N. Y. Here he spent three weeks collecting supplies, remanshaling his forces (which consisted of over 4,000 infantry troops, 20 dragoons, and an artillery train of 10 guns), threatening Prevost's St. Lawrence communications, and preparing his own. Ordered by Armstrong to descend the Châteauguay, he set out on October 20, and had made camp about 15 miles from the mouth when he was opposed a short distance below by some hundreds of troops under Lieut. Col. Charles Michel d'Irumberry de Salaberry, who was subsequently joined in a second line of defense by Col. George Macdonnell with 600 seasoned militia, thus bringing the total British forces to 1,590 men, about one fourth of whom consisted of raw troops and Indians. All except the Indians were French Canadian. Salaberry had skillfully fortified his position, and to turn his flank Hampton sent 1,500 men across the Châteauguay. They were driven back from the ford they were seeking by Macdonnell and became entangled in the woods. Confused by this mishap and by a ruse of Macdonnell, who by scattering his buglers gave an impression of a large advancing force, Hampton broke off a frontal attack which he had launched with some success on Salaberry, and retired. Three days later, learning that Wilkinson had not yet moved, and considering his own force inadequate to attack Prevost, he reascended the river to Chateaugay Four Corners. A week later he received a dispatch from Wilkinson asking that supplies be forwarded and that Hampton advance to the St. Lawrence rendezvous. To this Hampton could only answer that he was without supplies, that the junction on the St. Lawrence was now impracticable, and that he himself proposed to retire forthwith to Plattsburg. Wilkinson received this reply on November 12, a day after his disastrous defeat at Chrysler's Field. He retired across the border into winter quarters on the Salmon River, and the invasion came to an end. Losses in the Châteauguay clash amounted to less than 100 killed and wounded on both sides.

CHATEAUNEUF-DE-RANDON, shā-tō-nūf'dē-rān-dōn', village, France, in the Department of Lozère, 12 miles northeast of Mende, on a 3,980-foot hill. Formerly fortified, it is celebrated for a siege sustained in 1380 by an English garrison against troops commanded by Bertrand Du Guesclin. The English governor, hard pressed,

promised to surrender to Du Guesclin at the end of 15 days if no help had arrived. Before the time elapsed, Du Guesclin died, and his successor called on the governor to yield. The latter replied that he would surrender only to Du Guesclin. Informed of the hero's death, the governor laid his sword on Du Guesclin's bier. Pop. (1946) 257.

CHATEAURENAULT or **CHATEAURENAUD**, shā-tōr-nō', or **CHATEAUREGNAUD**, shā-tōr-nyō', MARQUIS DE (FRANÇOIS LOUIS ROUSSELET), French naval officer: b. Sept. 22, 1637; d. Paris, France, Nov. 15, 1716. He fought under the vicomte de Turenne in 1658, and three years later joined the navy. In 1664 he saw service against the Barbary pirates, and by 1672 had attained the rank of captain. Appointed rear admiral in 1673, he was active in the war with the Dutch. In 1689 he commanded a squadron which carried James II to Ireland, and he fought Admiral Arthur Herbert at Bantry Bay. He served under the comte de Tourville at Beachy Head in 1690, and off Cape St. Vincent in 1693. On Tourville's death (1701), he became vice admiral of France. In 1702 he escorted a convoy of Spanish treasure ships to Vigo, but he was badly defeated there by a fleet commanded by Sir George Rooke. Châteaurenault was created a marshal of France in 1703.

CHATEAUROUX, shā-tō-rōō', town, France, capital of the Department of the Indre, situated on the Indre River, 60 miles southeast of Tours. It has factories manufacturing woolen goods, agricultural machinery, and paper, and processing food, tobacco, and leather. The home of Comte Henri Gratiot Bertrand (q.v.) contains a museum of Napoleonic souvenirs, paintings, and other collections. Among other points of interest are the Church of the Cordeliers (13th century), the Church of St.-Martial (12th to 15th centuries), and the Château-Raoul (15th century), seat of the prefecture. The château is built on the site of a castle erected in the 10th century by Raoul le Large, lord of Déols, from which the town derives its name. From 1612 to 1736, Châteauroux was a duchy of the house of Condé, and from 1742 to 1744, of Marie Anne de Mailly-Nesle, the cynical young Marquise de La Tournelle who acquired the duchy and a princely income as mistress of Louis XV. Pop. (1946) 31,195.

CHATELET, shā-tlē', MARQUISE DU (GABRIELLE ÉMILIE LE TONNELIER DE BRETEUIL), French writer: b. Paris, France, Dec. 17, 1706; d. Lunéville, Sept. 10, 1749. She received an excellent education in languages, philosophy, physics, and mathematics, and in 1725 married the marquis du Châtelet-Lomont. In 1733 she became the mistress of Voltaire, who resided with her, first at Montjeu, and later (1734-1749) at the Château de Cirey. Her *Traduction des principes de Newton* (1756) helped to spread Sir Isaac Newton's ideas in France. Among her other published works are *Institutions de physique* (1740) and *Dissertation sur la nature et la propagation de feu* (1744).

CHATELET, town, Belgium, situated in Hainaut Province, on the Sambre River, 3 miles east of Charleroi. In a coal-producing region, it has iron and steel works and chemical plants. Pop. (est. 1948) 14,857.

CHATELET, anciently a small castle. The word is a diminutive of *château*, from *castel-*

lum, a diminutive of *castrum*; or from *castellatum*, a diminutive of *castellum*, castle. The term, in later times, has been applied to certain courts of justice, established in several cities in France. The Grand Châtelet, in Paris, was the place where the presidial or ordinary court of justice of the prévôte of Paris was kept, consisting of a presidial, a civil chamber, a criminal chamber and a chamber of police. The term signified the same at Montpellier, Orleans, etc. When Paris was confined to the limits of the old city (*cité*), it could be entered only by two bridges (Le Petit Pont and Le Pont au Change), each of which was fortified with two towers—a smaller one in the wall, facing the city, and a larger one before the bridge, toward the country. These two exterior turrets were the Grand and Petit Châtelet. The tradition that the Grand Châtelet was built by Julius Caesar, though adopted by some, is not well supported; but it is certain that the great tower was standing as early as the siege of the city by the Normans (885). The Grand Châtelet was the castle of the counts of Paris, and therefore the seat of all the royal courts of justice within the city and county, and also of the feudal court. The city had no proper jurisdiction whatever; its bailiff or provost (*prévôte*) was appointed by the king, and was president of the court (though only nominally, because he had no voice in the judgments), and, by virtue of his office, leader of the nobility. The office of provost of the merchants (*prévôte des marchands*; in other cities *maire*), established before the former, and afterward united with it for a time, was finally separated from it in 1388. The business of the Châtelet was transacted by the deputies of the bailiff (*lieutenants*), of whom there were five, three for civil causes, one chief judge of criminal cases, and a lieutenant-general of police (*lieutenant-général de la police*). The latter, indeed, was Minister of Police for the whole kingdom, and the extent of his functions and power, particularly after the new arrangement made by the celebrated d'Argenson under Louis XIV, rendered him one of the most important officers of the state. In the Châtelet, however, he held only the fourth place. The whole court of justice was composed of 57 counsellors, with 13 state attorneys and a multitude of subalterns, as 63 secretaries or *greffiers*, 113 notaries, 235 attorneys, etc. All these offices were sold. The place of the first officer of the civil chamber was rated at 500,000 livres; that of a notary at 40,000 livres. The Châtelet was first in rank after the Supreme Courts (*cours souveraines*).

CHATFIELD-TAYLOR, chăt'feld tā'lēr, Hobard C., American author: b. Chicago, March 24, 1865; d. Santa Barbara, Calif., Jan. 16, 1945. He was graduated at Cornell University in 1886. In 1888-1890 he was editor of *America*, was consul of Spain at Chicago in 1892-1894, and became a member of several honorary societies of Spain, France, Italy and Portugal. He has written *With Edge-Tools* (1891); *An American Peeress* (1893); *The Land of the Castanet* (1896); *The Vice of Fools* (1898); *The Idle Born* (1900); *The Crimson Wing* (1902); *Molière, a biography* (1906); *Fame's Pathway* (1909); *Goldoni, a biography* (1913); *Chicago* (1917); *Cities of Many Men* (1925); *Tawny Spain* (1927); and *Charmed Circles—A Pageant of the Ages from Aspasia's Day to Ours* (1935).

CHATHAM, Earls of. See **PITT, WILLIAM.**

CHATHAM, municipal borough, England, naval arsenal and seaport, in County Kent, on the Medway, 30 miles east-southeast from London, practically forming one town with Rochester. As a parliamentary borough it includes Gillingham and Rochester, and returns two members. The great features of Chatham are the naval and military establishments here and in the vicinity. The dockyard was founded by Henry VIII and enlarged by Queen Elizabeth; and during her reign Upnor Castle, on the left bank of the Medway, was erected to protect the dock and shipping. Despite the fire from the castle, however, in June 1667 Van Ghent, a vice-admiral of Michel de Ruyter, succeeded in breaking the chain stretched across the river, burned and sank several ships, and retired bearing off the warship, the *Royal Charles*, as a prize. The former lines of fortifications have been replaced by modern forts. With its extensions, the royal dockyard now extends for about three miles along the Medway, and is thoroughly equipped with building slips and floating docks, making it one of the most important naval bases in the kingdom. The military establishments include extensive infantry barracks, and barracks for the royal marines; the headquarters of the royal engineers, arsenal and park of artillery, and hospitals. The fortifications are intended as a defense for London, a protection against an invasion from the south coast. Chatham is one of the chief shipbuilding towns of England. Charles Dickens lived some time in Ordnance Place, Chatham. The remains of a Roman cemetery have been discovered at Chatham. Pop. (1946 est.) 40,400.

CHATHAM, chāt'ām, seaport town, New Brunswick, Canada, county seat of Northumberland County, on the right bank of the Miramichi River, 12 miles from its mouth, and on a branch of the Canadian National Railway, 98 miles northeast of Fredericton. It is the largest town on the north shore of the province. The harbor accommodates ships of large draught and the town has a considerable export trade in fish, tanning bark, deals, lath and finished lumber. Its manufactories include small saw and pulp mills, foundries, shipyard, sash and door factories. The town, founded in 1800, has 5 churches. Pop. (1951 est.) 4,300.

CHATHAM, borough, New Jersey, in Morris County, altitude 230 feet, 12 miles west of Newark, on the Passaic River and the Lackawanna Railroad. It is mainly a residential suburb of New York, famous for its roses. It was incorporated as a village in 1892 and as a borough in 1897. The borough owns the water supply and has a mayor and council. Pop. (1940) 4,888; (1950) 7,321.

CHATHAM, city, Ontario, Canada, county-seat of Kent County, on the Thames River, the Canadian National, Canadian Pacific, and Père Marquette railways, 45 miles northeast of Detroit and 67 miles southwest of London. Its site was chosen and named by Governor John Graves Simcoe in 1795. Chatham is center for a rich grain, tobacco, fruit and stock raising district. It is served by nine banks and is the seat of a United States consulate. It has saw, flour and

woolen mills; foundries and machine shops; canneries; manufactories of sugar, concrete and tobacco. There is natural gas in the vicinity. The city has many handsome buildings, including two large hospitals, a fine Collegiate Institute and the Ursuline Academy. Its natural attractions include Tecumseh Park, set amid beautiful scenery. It has a radio station, a daily newspaper, a Board of Trade and Industrial Bureau. Pop. (1951 est.) 20,000.

CHATHAM ISLANDS, a volcanic group politically attached to New Zealand, situated between 43° and 45° S. latitude and 176 to 177° W. longitude, 537 miles east of Lyttelton, New Zealand, to which geology and plant and animal life show they were once joined. They comprise Chatham, Pitt, and South East islands plus a few uninhabited rocks, with a total area of 372 square miles. The original inhabitants, the Moriori, of Polynesian stock, migrated there from New Zealand about 1200 A.D. When Lieut. William Broughton of H.M.S. *Chatham* discovered the islands in 1791 he estimated the population at 1,600, but there is evidence that it had been larger. Between 1809 and 1838 the islands were frequently visited by sealers and whalers. In 1835 some Taranaki Maoris seized the whaler *Lord Rodney* and forced her captain to transport 900 of them—men, women, and children—to Chatham Island where they took possession. Some of the Moriori were killed and others enslaved, while disease—measles, and especially influenza—took a heavy toll of the rest. The last pure blooded Moriori died in 1933. On Chatham Island (348 square miles) is the chief town, Waitangi. The main industries are sheep and cattle farming and fishing, the catch being shipped to Australia. Pop. (1951) 471, including 266 classed as Maori.

CHATI, shā-tē', a wildcat (*Felis mitis*), ranging from Mexico to Paraguay, in warm lowlands, and woods. The body, including the head, is from 24 to 27 inches long, the tail about 14 to 18 inches. The fur is soft and tawny, spotted with black. This cat is by some naturalists considered a variety of the margay (*Felis tigrina*).

CHATILLON-SUR-SEINE, shā-tē-yōn-sūr-sān', commune, France, in the department of Côte-d'Or, 43 miles northwest of Dijon, on the Seine. There are interesting medieval churches and a castle built by Auguste Marmont, which is surrounded by a large park. Napoleon held a congress here with the Allies in 1814. Two American armies joined forces here on Sept. 12, 1944 during World War II. Pop. (1946) 11,673.

CHATRIAN, shā-trē-än', **Alexandre.** See **ERCKMANN-CHATRIAN.**

CHATSWORTH, chāts'wūth, England, the celebrated estate of the dukes of Devonshire, situated in the parish of Edensor, in Derbyshire. It was among the domains given by the Conqueror to his natural son, William Peveril. It was purchased in the reign of Elizabeth by William Cavendish, who commenced to build a mansion on it, which was completed by his widow, the Countess of Shrewsbury. Mary, Queen of Scots, was imprisoned here for 13 years. The present building was nearly completed by the 1st duke of Devonshire, and a new wing was added by the 6th duke.

CHATTAHOOCHEE, chăt-à-hōō'chê, town, Florida, in Gadsden County, at an altitude of 68 feet, 47 miles northwest of Tallahassee, two miles south of the Georgia state border, on the Apalachicola River, where it is formed by the juncture of the Chattahoochee River with several minor tributaries. It serves as a junction for the Louisville and Nashville, Atlantic Coast Line, Apalachicola Northern, and Seaboard Air Line railroads. The name of the town is from the Seminole Indian language, meaning "marked rock." The town's main industry is the tending of the Florida State Hospital for the Insane, founded there in 1876. This is a huge institution, the largest of its kind in Florida, and it has the unique distinction of being the only hospital in the state admitting all indigent residents, white or Negro, free. There are over 4,000 patients here, living in white green-roofed buildings that are scattered about the spacious, landscaped grounds. The institution is a town within itself, containing a funeral home, barber shop, beauty shop, and a police and fire department. Pop. (1950) 8,466.

CHATTAHOOCHEE, river, in the north-eastern part of Georgia, rising in the Appalachian Mountains, and flowing first west and then south, forming for a considerable distance, the boundary between the above state and Alabama. In its lower course, after the junction of the Flint River from the east, it is named the Apalachicola River and is navigable to Columbus for steamboats. Total course, about 410 miles.

CHATTAHOOCHEE STAGE, in American geology, rocks laid down in older Miocene, or according to more recent authorities, in Oligocene time along the Atlantic coast of what was then the continent of North America. Strata of this stage probably extend, except for a break in Maryland and Virginia, from Cape Cod to Texas, and in the north are clays and uncompact sand, changing to limestones in the south. See also OLIGOCENE SERIES; TERTIARY SYSTEM.

CHATTANOOGA, chăt-à-nōō'gā, city, Tennessee, port of entry, and Hamilton County seat; altitude 674 feet; on the Tennessee River; on the Nashville, Chattanooga and St. Louis; Tennessee, Alabama and Georgia; Central of Georgia; and Southern railroads; on federal and state highways; 110 miles southwest of Knoxville. There is a municipal airport with service from three major airlines. The Georgia state line is part of the city's southern boundary, and the middle of the Tennessee River (here making a rectangular turn on the east side of Moccasin Bend) forms part of the north and east line of the city. Across the river to the north is the suburb of North Chattanooga; beyond it is Signal Mountain, rising sheer above the Grand Canyon of the Tennessee, with Raccoon Mountain on the south bank. South from Raccoon, just outside the city limits, is Lookout Mountain. The eastern slope of Missionary Ridge is the city limit on the east. Several national highways enter the city by tunnel. The business section is near the river with two bridges a block apart (Walnut and Market Streets); even here the contour is sharply broken by Cameron Hill with Boynton Park and an observatory. The Union Station serves the first two railways named; the Terminal Station, about five blocks

further from the river, serves the other two. South of the tracks, connecting the two stations, the main factory section extends across the Georgia line. The better residential sections are on the slopes of the hills and across the river in the suburbs of North Chattanooga and Dallas Heights. Just over the Georgia line is Fort Oglethorpe, at one time a United States Army Post, and the main part of the Chickamauga and Chattanooga National Military Park (1890; 8,456 acres). The other large part of this park is on Lookout Mountain (3,000 acres, taken over in 1935 from a mountain park planned and in part financed by Adolph S. Ochs). Orchard Knob, on the eastern edge of downtown, is also a part of the Military Park, which preserves with appropriate markers and reconstructed roads, the fields of the battles of Chickamauga (q.v.) and Chattanooga (see CHATTANOOGA, BATTLE OF), the former (Sept. 19-21, 1863) a defeat; and the latter (Nov. 24-25, 1863) an important victory for the Union Army, making possible Sherman's march through Georgia. In downtown Chattanooga are the Confederate Cemetery on Third Street, and the 20-block National Cemetery with 15,000 graves. In the Union Station is exhibited the "General," a locomotive used in April 1862 by 21 Union raiders, led by James J. Andrews, Federal spy, in an attempt to cut Confederate rail communications from Atlanta. They were captured near Chattanooga, and Andrews and seven of his men were executed.

Public Buildings.—In the city the principal buildings are: the fine modern post office and federal courthouse (1934); the 12-story Read House Hotel (1926; cost \$2,500,000), on the site of the Crutchfield House (1847); the Soldiers and Sailors Memorial Auditorium, with an arena seating 5,500; the first Presbyterian Church (1910), with windows by Blashfield; the Ochs Memorial Temple (1928), gift of Adolph S. Ochs in honor of his parents; and the Tudor Gothic quadrangle of the University of Chattanooga on a 15-acre campus.

Educational Facilities.—With two outstanding preparatory schools for boys and one for girls, a university, and a well-organized public school system, Chattanooga is one of the leading educational centers of the South. The University of Chattanooga was established in 1886. Until 1907 this school was U.S. Grant University, sponsored by the Methodist Episcopal Church. It is coeducational, and in April of alternate years holds an institute of public affairs. The public school system includes a vocational training school. Chattanooga has a Little Theater, a Symphony Orchestra, a Civic Chorus, and an Opera Association.

TVA.—Since 1935, the city has been main headquarters of the Tennessee Valley Authority. The series of dams on the Tennessee River give Chattanooga and Knoxville access for freight to Alabama points on the Tennessee, and to the Ohio and Mississippi rivers. The city's Electric Power Board buys power wholesale from the TVA transmission system, and the rates for electric service are among the lowest in the United States. Widespread use of the TVA low-priced electricity is made by commercial and industrial consumers. Domestic consumption is now three times the national average.

Trade and Manufactures.—The nearness of the city to power and fuel supplies makes it a natural manufacturing center. The type of iron

ore available here is like that of Birmingham, Ala., and only here and in Birmingham has the southern iron industry advanced to the stage of fabrication. Chattanooga makes farm implements, oil well and waterworks machinery, structural steel, stoves, boilers, brass, copper, and other nonferrous products; also other products, including textiles, furniture, patent medicines, chemicals, and glass. The variety was great even before low rates for power attracted new industries. The surrounding country grows fruit, truck, and farm crops.

Recreation and Amusements.—The city has a considerable tourist industry. Its battlefields are studied by officers from the United States Army War College, and casual visitors come to see the Military Park and the beautiful river and mountain scenery—particularly the Lookout Mountain Incline Railway (1897; third on this site) with two cable cars, on an incline 4,750 feet long; remarkable caves reached by electric elevators; the Falls Cave, 260 feet below ground, with Ruby Falls (145 feet high) and huge stalactites; and Twin Caves, at a 420-foot level, known to the Indians and a refuge in Civil War times; and the strange rock formations of Rock City (with beautiful gardens) and Fairyland (where the Tom Thumb golf craze started in 1927), on the Georgia end of Lookout Mountain. Chattanooga has a Tri-State Fair each September. Chickamauga Lake, a 40,000-acre man-made lake created by TVA through the construction of Chickamauga Dam on the Tennessee River, has increased the popularity of many water sports.

History.—Chattanooga is an Indian name, meaning "rock rising to a point," referring to Lookout Mountain. Several Indian trails met here: the Chickamauga Path ran from the mouth of Chickamauga Creek, a little northeast of present Chattanooga, into upper East Tennessee; the Great War Path went over Lookout and then south; the Shawnee Trail led from Williams Island (northwest of the city) into the Cumberland Valley. Warlike Cherokees who settled on the Chickamauga after 1776, and were burned out in 1779 by Evan Shelby, moved west of Lookout Mountain to villages called the lower Chickamauga towns, where they were a threat to the white settlers until the Nickajack Expedition under Maj. James Ore crushed them in 1794. A ferry at the south end of Williams Island (just west of the present city) was established in 1803 by John Brown, a half-breed Cherokee. After 1815 this site became an important Indian trading post, called Ross's Landing. From 1817 to 1838, Brainerd Mission (Congregational) was carried on at a spot just outside the southeast border of the present city. This mission (established by the Rev. Cyrus Kingsbury and named for David Brainerd, 18th century missionary to New Jersey Indians) gave its name to Missionary Ridge. The first permanent white settlement was made about 1835. A post office was established here in 1837 and named Chattanooga in 1838; the town was chartered in 1839. It was a center for the salt trade from Virginia to Tennessee, and soon had considerable river trade in flour, whisky, bacon, iron, and cotton cloth. The Western and Atlantic Railroad reached Chattanooga in 1849, and in 1851 it became a city. Its river trade in cotton rivaled that of Memphis for a few years, but before the war rail transportation had become far more important than river trade;

Chattanooga had rail connection with Knoxville in 1855 and with Memphis in 1857. In the War between the States, the Union armies struck at Chattanooga in 1862 and 1863 in an attempt to separate the eastern and western armies of the Confederacy. The campaign of 1862 was a failure. That of 1863 began with the defeat at Chickamauga and ended with the success of the greatly augmented Union forces in the spectacular battles on the mountains around the city. Until the end of the war, Chattanooga was a Union base. A terrible flood in 1867 helped wash out a smallpox plague, but smallpox struck again in 1883, cholera in 1873, yellow fever in 1878. The iron industry had a faint start about that time, and in that year Adolph S. Ochs bought the *Chattanooga Times* (established in 1869) and made it a great paper and his stepping stone to *The New York Times*.

Chattanooga was one of the first cities in the country to adopt the commission form of government, and it still operates under that system. It occupies an area of 27.42 square miles. The annual average temperature is 61.4°F., the average winter temperature being 41.6° and the average summer temperature, 76.8°. The annual rainfall averages 52.02 inches.

There were concentration camps near Chattanooga in the Spanish-American War and World War I and in the latter, training camps for men, officers, and medical corps. In 1935, first TVA and then national defense measures again stimulated the city's growth and prosperity. The population jumped at every decennial census except 1900, and it more than doubled from 1920 to 1930, partly through the annexation about 1929 of suburbs with a combined population in 1920 of over 14,000; (1860) 2,545; (1870) 6,093; (1880) 12,892; (1890) 29,100; (1900) 30,154; (1910) 44,604; (1920) 57,895; (1930) 119,798; (1940) 128,163; (1950) 130,333.

CHATTANOOGA, Battle of. At the close of the battle of Chickamauga, Ga., Sept. 20, 1863, the Union Army, in withdrawing from the field, having interposed at Rossville, Ga., between Gen. Braxton Bragg and Chattanooga, advanced into that city the night of the 21st and morning of the 22d, and immediately began to fortify it. Bragg followed on the 22d, and his lines were soon established in front of the place, his left resting on the Tennessee River and Lookout Mountain, below the city, his center extending across the plain to the foot of Missionary Ridge, his right being established at the foot of the ridge and reaching toward the Tennessee River above. (See map, page 357.) The advance line of the Confederates was half way between the ridge and the city, upon a low intermediate ridge, at the right of which was Orchard Knob, an isolated knoll rising some 60 feet above the plain.

Lookout Mountain commanded the river line to Bridgeport and Stevenson, the main depots of supply. This necessitated a wagon-haul of 60 miles over the Cumberlands and the adjacent range of Walden's Ridge, all precipitous and barren mountains. The Union army was soon running short of supplies, the fall rains rendering the roads almost impassable. On October 19, the day that Gen. William Rosecrans had perfected the general features of a plan for regaining the river line of supplies, he was relieved from command and Gen. George H. Thomas assigned, who at once ordered the preparations inaugurated by Rosecrans to go forward.

Immediately after the battle of Chickamauga, Gen. Joseph Hooker with the 11th and 12th corps was sent from the Army of the Potomac and arrived at Bridgeport, Tenn., September 30. Gen. William Sherman, in camp east of Vicksburg, had been ordered up with four divisions. Gen. Ulysses Grant was sent to take general command. Upon arriving, October 23, he approved the plans for opening the river, and directed their execution. Gen. Hooker was to advance into Lookout Valley, and a cooperating force from Chattanooga under Gen. William F. Smith was to seize Brown's Ferry below Lookout

street's troops after three hours' fighting withdrew to the east side of Lookout, and the Wauhatchie or Lookout Valley remained thereafter in Union control. Abundant supplies by the river then reached Chattanooga by a short wagon-haul from Brown's Ferry. On November 4, shortly after the Battle of Wauhatchie, Longstreet's corps was detached by Bragg and sent to Knoxville. (See CAMPBELL'S STATION.)

The Battle of Chattanooga, which occurred three weeks later, embraced three days' operations, November 23, 24, and 25. At the opening Bragg's lines were as already described. Hooker

Chattanooga, Tenn., and vicinity.

Mountain, throw a bridge there, and form a junction with Hooker. These movements were successfully executed during October 27 and 28. The 11th corps (two divisions) and Geary's division of the 12th corps entered Lookout Valley the afternoon of October 28, the 11th corps proceeding to Brown's Ferry and formed a junction with Gen. Smith's troops from Chattanooga. Gen. John W. Geary, with six regiments of his division, halted near Wauhatchie Station. At midnight of the 28th Geary was attacked by Micah Jenkins' (John Bell Hood's) division, six regiments of Gen. James Longstreet's corps, supported by Evander Law's division. Carl Schurz's division coming to Geary's support, Gen. Long-

occupied Lookout Valley, the Army of the Cumberland and the 11th corps were on the lines about Chattanooga, and Sherman with three divisions had crossed at Brown's Ferry and was concealed behind the hills above Chattanooga and on the opposite side of the river from the city.

General Grant's force for his firing lines was about 60,000, and the Confederates' a little less than 40,000. The formidable natural positions of the latter were held to give them superior advantages.

Grant's plan of battle was for Hooker to hold Lookout Valley against Bragg's left. Sherman was to cross the Tennessee opposite the north end

of Missionary Ridge, which was unoccupied, and carry it to the railroad tunnel about half a mile south of its northern end. Sherman, then, astride of the ridge, was to move south; while Gen. George Thomas, with the Army of the Cumberland before the city, was to connect its left with Sherman's right, and together sweeping south they were to clear the ridge and the valley. As the engagement progressed, every feature of this plan was changed by unexpected developments.

At noon, November 23, General Thomas, being directed by Grant to ascertain if the Confederates still occupied their lines and camps between the city and Missionary Ridge, paraded five divisions in full view of the Confederate positions, which, as was afterward ascertained, was at first supposed to be a review. Thomas Wood's division was in the center advanced, Schurz's and Steinwehr's divisions of the 11th corps were reformed on the left, and Phillip Sheridan's and Absalom Baird's on the right. At a bugle signal at 1:30 P.M. the center advanced rapidly, and, after a sharp contest, captured Orchard Knob, and forced the abandonment of the entire line of the Confederates through the center of the plain, reversed the works at and near the Knob and held them. This was the first day's battle.

The night of the 23d Sherman with three of his four divisions, which had reached his concealed camps opposite the city and north of it, marched to the North Chickamauga, where 116 pontoon boats awaited him. These were filled with soldiers, floated down the creek to the river, and thence to the opposite shore, and by daylight of the 24th, 8,000 of Sherman's troops were in line fronting Missionary Ridge, two miles from it, and opposite its northern extremity, which point was not occupied by the Confederates until 2:30 in the afternoon. At 1 o'clock the three divisions, and one from the Army of the Cumberland which had covered the movement having crossed, the lines were advanced, and at 4 o'clock a range of unoccupied hills north of and overlooking the north end of Missionary Ridge was occupied without resistance, and strongly entrenched under the supposition that these formed the north end of the ridge contemplated in the order of battle. The mistake was due mainly to the misty weather, and the omission of any reconnaissance.

At 2:30 P.M. Patrick Cleburne's division arrived at the north point of the ridge and entrenched.

Gen. Thomas, having obtained Grant's permission to make a demonstration against the Confederate position on Lookout, made ready to move at an early hour on the 24th.

The Confederates held the top of the mountain, which was a narrow plateau 1,700 feet above the valley, protected by perpendicular palisades varying from 75 to 250 feet high. From the foot of the walls of rock the mountain sloped westward to Hooker's position in Lookout Valley eastward to the plain south of Chattanooga, while its north slope descended to the Tennessee River opposite Moccasin Point. It was approximately a mile and a half from the foot of the palisades to the valley. The battle took place on these slopes. No Union troops reached the top of the mountain during the engagement. The morning of the 24th, part of Stevenson's Confederate division occupied the summit, and part of Cheatham's division the slopes of the mountain.

Hooker's aggregate strength was something over 9,000. The Confederates, who sustained almost the entire attack until the western and northern slopes had been carried, did not number over 1,700.

The head of Hooker's column crossed Lookout Creek at Light's Mill near Wauhatchie, at 8 o'clock in the morning, and, concealed by the fog which hung over the mountain, marched directly up the western slope until the head of the line reached the base of the palisades. His line then faced toward the north point of the mountain, distant about two miles.

After an advance of a mile and a half with Geary's brigades, the troops struck the left flank of Walthall's line protected by slashed timber. This was carried, and in the face of stout resistance the Confederates were driven around the north point of the mountain, and across its northern slope. As Geary's attack opened, it was joined by other brigades, and it advanced with the swinging movement on the slopes of the mountain. Until the northern slope had been carried to the Craven House, the Confederates had no assistance. Their relief arrived after they had withdrawn some 400 yards from the Craven House. This position was held until 3 o'clock in the morning, when, the troops and supplies from the top having been withdrawn and safely started across the plain for the Missionary Ridge line, this final line was also withdrawn, and the mountain abandoned. The troops on the summit, on account of the fog, could do little damage to the Union lines. Hooker was materially assisted by batteries on the elevated points in Lookout Valley, and those across the river on Moccasin Point, which swept the northern slope. The next morning the Union forces occupied the summit.

The capturing of Lookout Mountain decided Gen. Bragg to withdraw his whole army from the plain to the crest of Missionary Ridge, except as heavy picket forces were left in the entrenchments at the base of the ridge.

Hooker's losses at Lookout, and the next day at Missionary Ridge, which were small but not definitely reported, were: killed, 81; wounded, 390. The Confederate loss was: killed, 21; wounded, 177; captured, 845; and missing, 208.

During the night of the 24th and the early morning of the 25th, Bragg concentrated his army on Missionary Ridge, and in the earthworks at its base. This was his first occupation of the crest of the ridge in force. His new line extended from Rossville, a distance of eight miles, to the north end of the ridge, and was composed of seven divisions.

The battle of the 25th opened soon after 7 o'clock by an assault of Sherman upon the north end of the ridge, defended by Cleburne. While some brigades reached the crest at different periods, none was able to maintain position there. The fighting of the troops sent in was persistent and most courageous, but Cleburne repulsed all assaults. The last one, about 3:30 P.M., was especially serious.

Grant, on Orchard Knob, observing this repulse, ordered Gen. Thomas to advance his four divisions at the center against the earthworks at the foot of the ridge as a diversion in favor of Sherman, hoping thereby to cause the withdrawal of Confederate forces from his front. The line was two and a half miles long, and faced the ridge at distances from three-quarters

of a mile to a mile from it. There were 11 brigades and 89 regiments in the lines as prepared for the assault. At a signal of six cannon shots from Orchard Knob the four divisions rushed for the earthworks at the foot of the ridge. On the summit opposed to this advance were 13 brigades and 16 batteries. The cannonading of nearly 100 guns from the crest was terrific, and the line was soon under rifle-fire from the works at the base, but the entire line of earthworks was captured as soon as the troops by running could reach them. Reforming their lines in the earthworks, Baird's division on the left and Johnson's on the right began the storming of the ridge without further orders. At the center in Wood's and Sheridan's divisions the orders as understood by most were to stop at the rifle-pits, but the men ignored these and started forward, and soon orders were received to go to the top. The whole line of brigades gained the crest so nearly together that it has always been difficult to determine which, if any one, was the first.

The long lines of the storming party moved up the slopes with few checks, and in an hour had carried three miles of the crest and captured 7 guns and about 2,000 prisoners.

Just as the orders were given Thomas for his assault at the center, Hooker, who had descended Lookout at 1 o'clock and started to attack the south end of the ridge in Rossville Gap, reached that position. He had been detained by the necessity of rebuilding a bridge over Chattanooga Creek. He at once sent a division through the gap and turned it north along the east side of Missionary Ridge. Another Union division assaulted and carried the south end of the ridge in the gap while Geary moved along the western base of the ridge and finally ascended to the crest, reaching it soon after the right of Thomas' assault had occupied it.

As Baird's division reached the crest, it turned northward and became hotly engaged with a Confederate brigade. Darkness coming on, the fighting ceased.

The losses at Chattanooga, including the three days' battles and the affairs in pursuit to Ringgold, were for Grant: killed, 753; wounded, 4,722; missing, 349; total, 5,824; for Bragg: killed, 361; wounded, 2,180; missing, 4,146; total, 6,687.

H. V. BOYNTON.

CHATTANOOGA, University of, an independent, endowed, accredited coeducational institution founded at Chattanooga, Tennessee, in 1886 by the Methodist Episcopal Church.

Through its colleges of Liberal Arts, Applied Arts, Fine Arts, and Division of Graduate Studies, the university offers accredited curricula in languages and literature, social studies, philosophy and religion, science and engineering, home economics, teacher training, physical education and health, military science and tactics, business administration, dramatics, art, and music. Two-year or junior college certificate programs are available in liberal arts, accounting, cooperative retailing, home economics, and secretarial science. Standard pre-professional work is offered in medicine, nursing, law, engineering, teaching, and ministerial training. Graduate work is currently limited to the master's degree in education, chemistry, and music. Through Chattanooga College the university offers a wide variety of late afternoon and evening courses on a credit and non-

credit basis to adults in the Tri-State area. A Senior ROTC unit is maintained on a voluntary basis.

The campus consists of twenty-five acres and twenty permanent buildings and is centrally located on a hill top in downtown Chattanooga. The value of the university plant is \$4,109,000 and the endowment totals \$1,200,000. The income from the annual alumni and citizens Sustaining Fund averages \$50,000. The Library contains more than 50,000 volumes with special TVA, scientific, and southern history collections. The Chattanooga Public Library, containing some 100,000 volumes, is housed in the same building, thereby making the combined facilities available to faculty and students. The university sponsors institutes, short courses, art exhibits, dramatic productions, and musicals, and serves as a cultural center of the area.

In 1950-1951, the faculty consisted of more than 100 teachers; the enrollment in the day colleges averaged some 1,200 students, and the evening college numbered about 600. There is also a summer school of two six-week sessions enrolling some 800 students each year. The Cadek Conservatory of Music, the preparatory division of the university, has a separate faculty of some 40 teachers and enrolls some 1,400 students annually on a noncredit basis. The Industrial Research Institute of the University engages in fundamental and applied research in the fields of science and engineering on a non-profit basis for local and national industries, government agencies, and foundations.

DAVID A. LOCKMILLER,
President, University of Chattanooga.

CHATTEL, chăt'tl (O.F. *chatel*, property), property movable and immovable, not being freehold. The word chattels is originally the same word with cattle, all property being reckoned in early periods by the number of heads of cattle possessed, or their equivalent. Chattels signified originally only movable property, but in course of time came to be applied to all property not held in feudal tenure. Chattels are divided into real and personal. Chattels real are such as belong not to the person immediately, but dependently upon something. Any interest in land or tenements, for example, is a real chattel; so also is a lease, a rent for a term of years, an interest in advowsons, etc. Chattels personal are goods which belong immediately to the person of the owner, and include all movable property. Chattels usually pass to the executor, except such, for instance, as trees, which may not be severed from the freehold, and therefore pass to the heir. But objects forming part of the real estate may become chattels upon being separated from it, as for example, ore, oil, timber, etc. *Chattels personal*, at common law, are transferable by agreement, when the transfer is made for a consideration; but if the transfer is made through a gift, the delivery of the chattel is necessary to confer title on the guarantee. Chattel is a more extensive term than goods or effects.

CHATTEL MORTGAGE, a transfer of personal property as security for a debt in such manner that upon default the chattel becomes the property of the mortgagee. In the absence of statute no special form is necessary, the terms depending to a great extent on the intention of the parties. Between the parties to a

mortgage, a delivery is not necessary, but to be binding on creditors, delivery to the mortgagee or notice to the creditors is necessary. In mortgage, title and possession pass; in pledge, possession passes, but title remains in the pledgor. At common law it was necessary for the chattel to be in possession of the mortgagor at the time the mortgage was given, so as to be binding against creditors; but if the mortgagor acquired title after the mortgage had been given, it was good as between the parties, but not as to creditors. In equity a chattel mortgage is considered in the nature of an executory agreement. See MORTGAGE.

CHATTERERS, formerly the popular name of certain inessorial birds of the family Ampelidae, genus of *Ampelis*, as the Bohemian chatterer or waxwing (*A. garrulus*) and the chatterer of Carolina (*A. cedrorum*). Now the *Cotingidae*. See WAX-WING.

CHATTERJI, chăt'tēr-jē, or **CHATTO-ADHYAYA**, Bankim Chandra, Indian novelist: b. Katalpara, Bengal, India, June 27, 1838; d. April 8, 1894. Bankim's father was an official in the service of the government. Bankim Chandra was educated both at Hugli College and at the Calcutta Presidency College. He was the first to receive the B.A. degree from the Calcutta University in 1858. In recognition of his services as a magistrate, the British authorities conferred on him the titles of Rai Bahadur and C.I.E. He was fond of literature even as a boy. At the age of 15, he published a book of poems entitled *Latit O Manash*. His first novel, *Durges-Nandini*, was published in 1864. This book created a literary sensation in Bengal and the author was hailed as a great literary genius. Tagore won international fame, but Bankim is called in Bengal, "The Emperor of Bengali Literature." His principal novels are *Durges-Nandini*, *Kapala-Kundala*, *Mrina-lini*, *Bisha-Brikha*, *Ananda Math* and *Indria*. Ever since the advent of the Nationalist movement in India, Bankim Chandra's *Ananda Math* has been exceedingly popular. This novel deals with the Sannyasi rebellion of 1772. The famous national song of India, *Bande Mataram*, appears in this book. This was originally used as a rallying cry against the English. The song, in part, reads thus translated:

Mother, hail!
Thou with sweet springs flowing,
Thou fair fruits bestowing,
Cool with zephyrs blowing,
Green with corn-crops growing,
Mother, hail.

Though now seventy million voices through thy mouth
sonorous shout,
Though twice seventy million hands hold thy trenchant
sword-blades out,
Yet with all this power now,
Mother, wherefore powerless thou?

This song is a source of inspiration to the Nationalists of India. In his literary life, Bankim Chandra was influenced by Ishwar Chandra Gupta. And Bankim influenced Rabindranath Tagore. In elegance of language and in loftiness of thought, Bankim's novels can be counted among the very best in any literature.

CHATTERTON, chăt'ēr-t'n, **Edward Keble**, English journalist and author: b. Sheffield

1878; d. Dec. 31, 1944. He was educated at Oxford, went to London and entered journalism, wrote on art and the drama for several journals; became sub-editor of the *Art Record* in 1902; sub-edited John Ruskin's manuscripts for the library edition of Ruskin 1902-1903; was London correspondent of the *Sheffield Weekly Independent* 1902; sub-editor of the *Daily Mail*, and editor of the *Lady's Realm* 1904-1906, and its dramatic critic in 1904-1908. He received a temporary commission as lieutenant in the Royal Naval Volunteer Reserve (1914), and was promoted to lieutenant commander (1918). His published works include *Sailing Ships: The Story of their Development from the Earliest Times to the Present Day* (1909); *Steamships and their Story* (1910); *Down Channel in the L'ivette* (1910); *The Romance of the Ship* (1910); *The Boy's Book* (1910); *The Story of the British Navy* (1911); *Fore and Aft* (1911); *Ships and Ways of Other Days* (1913); *The Romance of Piracy* (1914); *Ship Models* (1923); *Whalers and Whaling* (1925); *On the High Seas* (1929); *The Sea Raiders* (1931); *Sea Spy* (1937); *Secret Ship* (1939); *The Epic of Dunkirk* (1940); *The First Fifteen Months of War* (1941); *Fighting the U-Boats* (1941); *The Commerce Raiders* (1943); and *Beating the U-Boats* (1943).

CHATTERTON, Thomas, English poet: b. Bristol, Nov. 20, 1752; d. there, Aug. 24, 1770. Reading early became his ruling passion. Melancholy gave way to vivacity and vanity, and dreams of immortality. His father had accidentally obtained possession of a number of old parchments of the 15th century. Many of these were put to domestic uses in the family or served in the making of dolls, but several fell into the hands of Chatterton, who after a few days declared that he had discovered a treasure. He then procured glossaries of the old dialects of the country, and in 1768, when the new bridge at Bristol was completed, he inserted a paper in the *Bristol Journal*, entitled *A Description of the Friar's First Passing Over the Old Bridge, Taken from an Ancient Manuscript*. He was then but 16 years old. Upon being questioned as to the manner in which he had obtained it, he finally asserted that he was in the possession of several valuable old manuscripts, taken from an old chest in Redcliffe Church. He had been engaged for a year in the composition of several poems, which he attributed to different ancient writers, particularly to one Rowley. In 1769 he ventured to write to Horace Walpole, who was then engaged upon his *Anecdotes of Painters*, giving him an account of a number of painters who had flourished in Bristol, which Chatterton pretended to have discovered along with several ancient poems in that city, and received a polite answer. Discontented with his situation, he went to London. The favorable reception which he there met with from the booksellers inspired him with new hopes. He wrote for several journals on the side of the opposition and indulged the hope of effecting a revolution, boasting that he was destined to restore the rights of the nation. Failing to procure the rewards which he had expected, his situation daily became worse. Although extremely temperate, and often voluntarily confining himself to bread and water, he was frequently destitute even of these neces-

saries. At last, after having been several days without food, he poisoned himself in 1770, when not yet 18 years old. His works were extensively read as the public became acquainted with the history of his misfortunes. His poems, especially those written under the name of Rowley at the age of 15 years, display a vigorous and brilliant imagination, fertility of invention, and often a deep sensibility. Professor Walter William Skeat, in his introductory essay in his edition of *The Poetical Works of Thomas Chatterton* (1871), put an end to the long controversy over the genuineness of the Rowley poems, showing them to be Chatterton's own.

(Consult Roberts, Henry D., ed., *The Complete Poetical Works of Thomas Chatterton*, 2 vols. (New York 1906); Ingram, J. H., *The True Chatterton* (London 1910); Ellinger, Esther P., *Thomas Chatterton, the Marvelous Boy*, to which is added *The Exhibition*, a personal satire (Philadelphia 1930); Meyerstein, E. H. W., *Life of Thomas Chatterton* (New York 1930); Nevill, J. C., *Thomas Chatterton* (London 1948).

CHATTOPADHYAYA, Bankim Chandra.

See CHATTERJI, BANKIM CHANDRA.

CHAUCER, chô'sêr, **Geoffrey**, English poet: b. London, England, c.1340; * d. 1400. Geoffrey Chaucer, often called the father of English poetry, is the best-known English poet of the Middle Ages. His family, which came originally from Ipswich, in eastern England, has been traced as far back as 1260, when its members were often known by the name of Malyn as well as Chaucer. From the beginning they were connected with the wine business, especially as keepers of taverns; but quite early certain members of the family had associations with London. Since the name was originally Chausier—the French for “shoemaker”—it is interesting to note that the London associations were almost invariably located in Cordwainer-street Ward, the shoemakers' district. It would seem that the family had not completely lost its connection with the leather trade. John Chaucer, the poet's father, had a house in Thames Street, and it is probably there that the poet was born.

Chaucer would certainly have passed as an educated man in the 14th century, but as to how he acquired his schooling we are completely ignorant. It has been suggested, on rather slight grounds, that he may have attended the almonry school attached to St. Paul's Cathedral. Some scholars have accepted a late tradition that for a time he was a student of the law at the Inner Temple, but in this matter there seems as much reason to doubt as to believe.

In any case, Chaucer was at home in French and had acquired, by whatever means, a sufficient knowledge of Latin to read the Latin literature of most interest to him, especially the poetry of Virgil and Ovid. His knowledge of other classical writers is more fragmentary, but he made use of a considerable number of Latin medieval works which enjoyed a measure of popularity in his day. In the course of his life he acquired an adequate knowledge of Italian. He more than once mentions his love of books, and doubtless most of his rather wide but desultory knowledge was the result of his reading.

One way to advancement in Chaucer's day was through training in the household of an important person. Chaucer's father had served Edward III in one or two capacities, and it was

doubtless through his influence that in 1357 we find the young Chaucer a page in the household of the countess of Ulster, wife of Lionel, duke of Clarence, one of the king's sons. There he learned the ways of polite society, continued his education, and had an opportunity to know important people. When the countess celebrated Christmas that year at her Yorkshire house, John of Gaunt, another son of the king and later one of the most influential men at court, was present. He was Chaucer's generous and consistent patron.

By June 1367, Chaucer had become a “valetus” in the king's household, later being advanced to an esquire. When Edward invaded France in 1359, Chaucer accompanied him and was taken prisoner in the fighting near Rheims (now Reims). The king contributed £16 toward his ransom. In the negotiations preceding the Treaty of Breigny in 1360, Chaucer carried messages between England and the negotiators. Such employment was a natural prelude to his being used in more important missions.

A period of about six years, between 1360 and 1367, is a complete blank in our knowledge of Chaucer's life. Lionel was in Ireland as viceroy from 1361 to 1366, and it has been suggested that Chaucer may have been with him. The suggestion would help to account for the poet's description of a revolving house of twigs in *The House of Fame*, since it is thought that the idea was suggested by the wicker dwellings found in Ireland at that time. Chaucer could have learned of these, however, at second hand, and there are reasons for thinking that he was in the king's service for at least a part of this period.

Chaucer's Marriage.—At all events, by 1366 Chaucer was married to one of the demoiselles in the service of the queen. Her name was Philippa, and it is almost certain from the heraldic evidence on Thomas Chaucer's tomb that she was Thomas's mother and that her maiden name was de Roet. She was thus the sister of Catherine Swynford (widow of Sir Hugh Swynford), who was for many years John of Gaunt's mistress and ultimately his wife. Marriages between esquires and demoiselles of the royal household were quite common. If, as seems likely, Philippa is to be identified with the Philippa Pan' who was in the service of the countess of Ulster at the same time that Geoffrey was one of the countess' pages, their acquaintance was of long standing. Unfortunately we do not know the significance of the abbreviation “Pan'” attached to her name in the fragment of the countess' household accounts which has come down to us.

Visits to the Continent.—During the period from 1368 to 1387, Chaucer went to the Continent at least nine times. The purpose of these journeys is not always known, since the records which grant him letters of protection during his absence from the country or note the payment to him of various sums for his salary and expenses are often brief and tell us only that he was going on “secret business of the king.” But some of them give additional information which indicates that he was sometimes sent to negotiate a treaty, discuss the possibility of a military alliance, and perhaps deal with Italian bankers from whom the king had received loans. On at least one occasion he was a member of a commission to arrange a marriage between the young King Richard II and a princess of France. Most of his business took him to France, but on two

* Some authorities give his birth date as two or three years later.

of his missions he went to Italy, in 1372 and again in 1378. A remark in the *Clerk's Tale* in the *Canterbury Tales* suggests that on the latter trip he may have met the Italian poet Petrarch, but such a meeting is quite doubtful. In any case, the Italian journeys gave him an opportunity to acquire books, especially some of the works of Dante and Boccaccio, and strongly affected his literary work.

More important from the point of view of steady income were Chaucer's several positions in the civil service. In 1374 he was appointed comptroller of the customs and subsidy levied on the export of wools, skins, and tanned hides from London, with the usual stipulation that he keep the books and perform the duties in person. Such appointments were fairly normal for esquires of the king's household. He held the appointment until near the end of 1386. His new duties relieved him of attendance at court, and he was free to take up housekeeping. This he did by leasing an apartment over Aldgate, one of the city gates, where he continued to live during most of the time that he was employed in the customs. In 1382 he received the further office of comptroller of the petty customs, which he was allowed to exercise by deputy. We do not know whether he relinquished these offices voluntarily or was deprived of them. There were political changes at the time which make the latter not unlikely. Shortly before 1386, he had moved to Kent, where for a time he was a justice of the peace and briefly a member of Parliament.

Chaucer's last civil appointment (in 1389) was as clerk of the works, in which capacity his duties were to direct the maintenance and repair of Westminster Palace, the Tower of London, various manors used as royal residences, and the parks and gardens connected with these places. To these duties were added in 1390 those which fell to him when he was made a member of a commission on sewers, appointed to survey and repair the Thames embankment. While clerk of the works he was thrice on the same day robbed of the king's money, the sums approximating \$1,500 in American money. The robbers were captured, and when one of them confessed, the other two were hanged. Chaucer was not held responsible for the loss and was not replaced in office until nine months later. His advancing age, according to medieval standards, would have been a sufficient reason for retirement.

Chaucer's Sources of Income.—During most of this period, Chaucer was financially in very comfortable circumstances. His income was by no means confined to the salaries which went with his offices. The king encouraged vigilance on the part of his comptrollers of the customs by rewarding them with the value of the wool which anyone attempted to take out of the country without payment of duty. On one occasion Chaucer received the equivalent of nearly \$10,000 in this way. The crown also granted wardships of certain minors to those at court who were fortunate enough to receive such favors. These could be very profitable. From one such grant Chaucer derived approximately \$15,000 over the space of three years. From another he received a certain amount—we do not know how much.

On occasion Chaucer was given various sums by the king in recognition of his services. And we have records of the semiannual payment of annuities from the king and from John of Gaunt, both to Chaucer and to his wife. In 1378 his

condition was apparently sufficiently substantial to permit him to act as surety for Sir William Beauchamp to the extent of £400 a year, a large sum in the 14th century. It is likely that during the middle period of his life Chaucer and his wife enjoyed an income of between \$10,000 and \$15,000 a year by modern reckoning.

It is worth observing that Chaucer, like Shakespeare, was an active man of affairs. The nature of the missions and employments in which he was used during the more active period of his life is a fair indication of his business ability and his tact.

Unfortunately, after 1386 his fortunes seem to have fluctuated and there were times when he appears to have been short of money. Some of the loans which he obtained from the Exchequer were probably only to insure prompt payment when instalments on his annuity were due. But others, especially in the last few years of his life, were so small as to show that he was in need of ready money. In 1388 he sold his annuity for a lump sum. It is hardly likely that as he faced old age he would have sacrificed continuing security unless he had some pressing need for a substantial sum of money. In 1398 he and one John Goodale were sued for £12 and £13, respectively. The knowledge which he shows of the dishonest practices of alchemists in the Canon's Yeoman's prologue and tale in the *Canterbury Tales* and the warmth with which the speaker at times expresses himself cause one to wonder whether Chaucer himself had ever fallen a victim to their practices. This of course is pure conjecture.

An added adversity, which probably befell him in 1387, was the loss of his wife. Since the last payment to her on her annuity was made in June of that year, it is assumed that later in the course of the year she died. There is no proof that Chaucer owed any of his worldly success to her influence, but it would seem that her social position was slightly better than his. In 1386, along with Henry, earl of Derby (son of John of Gaunt, and one day to be King Henry IV), and six others, she was admitted into the fraternity of Lincoln Cathedral. John of Gaunt, who with other distinguished people had been admitted in previous years, was present on the occasion, and it was apparently something of an honor. We can but observe that Philippa was so honored and Geoffrey was not. It may be noted also that she was seemingly in high favor with John of Gaunt.

Chaucer's Last Years.—In the last years of his life (by 1395) Chaucer was apparently in the service of Henry, earl of Derby, though we do not know in what capacity. When on Sept. 30, 1399, Henry was declared king, Chaucer promptly sent him a copy of his little poem, *A Complaint to His Empty Purse*, with an additional stanza of compliment. The new king was equally prompt in his response. On Oct. 13, the day of his coronation, he granted Chaucer an annuity of 40 marks a year in addition to the annuity of £20 which he had from Richard. Chaucer lost the letters patent—he was obviously getting old—and he had to be granted an exemplification, or reaffirmation, of the grant. Two months later, he leased a house in the garden of St. Mary's chapel, Westminster Abbey. According to an inscription on his tomb in Westminster Abbey, he died Oct. 25, 1400.

There are problems in Chaucer's biography

which still are somewhat obscure. In 1390-1391 he was appointed joint forester of North Petherton Park in Somersetshire, and in 1397-1398 sole forester. What his duties were is not known, but it is not clear how at his age he could have discharged very actively the duties of an office at such a distance from the place where he was living—apparently in London or Greenwich. Some years later Thomas Chaucer held the same post.

Another detail about which there is a sharp difference of opinion is the record of a deed in 1380 in which a certain Cecilia Chaumpaigne released Chaucer of her rights of action against him "*de raptu meo*." In view of the vague way in which the word *raptus* was used in charges of the time, it is generally assumed that Chaucer, and others, were involved in a case of abduction, possibly to prevent or control Cecilia's marriage. However, an article written from a modern legal point of view (P. R. Watts, "The Strange Case of Geoffrey Chaucer and Cecilia Chaumpaigne," *Law Quarterly Review*, 63:491-515, London 1947) argues for the strict interpretation of the matter as one of rape. The question is by no means settled.

The only child mentioned by Chaucer is his "little son Lewis" for whom he prepared the *Astrolabe*, an elementary treatise on the instrument. But it is fairly certain that another son was the Thomas Chaucer who became speaker of the House of Commons and was one of the regents governing the country during the infancy of Henry V. An Elizabeth Chaucy, toward whose expenses John of Gaunt contributed £51 when she became a nun in the exclusive convent of Barking, may have been a daughter. Concerning an Agnes Chaucer and one or two others who are mentioned in contemporary records we know nothing.

Literary Career.—From what has already been said it is clear that for Chaucer writing was an avocation. While we need not suppose that his reputation as a poet had no effect upon his position at the court, we may be sure that he read and wrote poetry chiefly because he enjoyed doing so. At the time he wrote his first important poem, *The Book of the Duchess*, he was already intimately acquainted with the 13th century *Roman de la Rose*, on which all poets in the 14th century seem to have been brought up, and with a number of poems of the French poet Guillaume de Machaut, totaling several thousand lines. The acquaintance is proved by innumerable echoes of phrases, lines, and sometimes longer passages of these poems in *The Book of the Duchess*. It is clear that most of his reading at this time, apart from Ovid, was in French poetry, upon which his own early work was modeled almost exclusively, reflecting the fashions and conventions in vogue in France at the time.

His two journeys to Italy broadened his horizon. Sometime between the writing of *The Book of the Duchess* and *The House of Fame*, he had read at least a part of Dante's *Divine Comedy*, a work which he may have acquired on his first trip. After his second trip, on which he must have obtained a collection of the more important works of Boccaccio except the *Decameron*, there is frequent evidence in his work of his reading in Italian literature. He did not forget what he had learned from French poetry, but the influence of Boccaccio became increas-

ingly evident and is most apparent in the *Knight's Tale* and in *Troilus and Criseyde*. The division between a French period and an Italian period in Chaucer's work, if properly understood, is not without value; but the line must not be sharply drawn, and it must be remembered that his interest in French poetry continued throughout his life.

The last phase of Chaucer's work, represented mainly by the *Canterbury Tales*, is often called his English period. Having made his own all that he had learned from French and Italian literature, and having acquired the mastery of his art which enabled him to follow his own intuition, he wrote without thought of models and conventions. The artist had become the man.

By his own admission Chaucer made many "ballades, roundels, viroles" for Love's festivals. Most of these are lost, but a score of shorter poems survive, some written early in his life, others scattered through his career. Besides love poems belonging to standard French types there are humorous and satirical ballades and conventional religious poems. One of the earliest, his *A.B.C.*, is a conventional prayer to the Virgin, supposedly written at the request of the Duchess Blanche, first wife of John of Gaunt, and based upon a French original by Guillaume de Déguileville.

The love complaint is represented by the *Complaint unto Pity*, whom he found dead, and the *Complaint to His Lady*, who is compounded of all virtues except pity for the poet. The *Complaint of Mars*, with its astronomical imagery, is thought by some to reflect a court intrigue. The ballade of *Rosamonde* is a courtly love address to a lady and is short and graceful. A group of ballades, *The Former Age*, *Fortune*, *Truth* (his best-known short poem), *Gentillesse*, and *Lack of Steadfastness*, are associated by a common dependence, at longer or shorter range, upon the Roman philosopher Boethius, though the ideas are supplemented from other sources. The *Envoy to Scogan* and the *Envoy to Bukton* (1396) are humorous epistles, the former seeking help from a friend at the court, the latter whimsically counseling his friend against marriage. The charming little *Words to Adam Scryveyn* is later than his translation of Boethius and *Troilus and Criseyde*, both of which are mentioned in the poem, and humorously complains about his too often having to correct the mistakes of his copyist. The *Complaint to His Empty Purse* has already been mentioned. Its envoy to Henry IV probably represents the last bit of verse that he wrote.

That Chaucer made a translation of the *Roman de la Rose* is certain, and it would be natural to think that it was one of the undertakings which he first attempted and in which he served his apprenticeship in verse. The translation (about a third of the poem) which is usually printed in editions of his works is almost certainly not all his. There is nothing, however, in the first 1,705 lines to hinder us from believing that this portion is by Chaucer. The rest contains non-Chaucerian rhymes and is characterized by other features which lead most scholars to reject these later sections from the canon of his writings.

In September 1369, John of Gaunt's wife Blanche died of the plague, one month after Philippa had died from the same cause. *The Book of the Duchess*, written soon after, is an

elegy in her honor, intended for the duke. After an introductory episode telling the story of Ceys and Alcione (Ceyx and Halcyone), which admirably sets the key for what follows, the poet describes a vision in which he is led to a disconsolate knight dressed in black and sitting dazed at the foot of a tree. In the course of the conversation the knight reveals the cause of his grief and describes the beautiful woman whom he has lost. The poem is full of echoes of Chaucer's reading, but the plan is his own.

In spite of the opinion of many critics the poem has very real virtues, not the least of which is the delicate way in which Chaucer contrives to put all the compliments to the lady in the mouth of her bereaved husband. Nor can one praise too highly the restraint which Chaucer shows in bringing the poem quickly to an end when the knight finally reveals the nature of his loss in unequivocal terms, thus avoiding the danger of oversentimentalizing the situation. It is Chaucer's first original long poem, and as a first poem is one of which any poet could be proud.

Chaucer as a court poet was naturally also an "occasional" poet. There were frequent occasions to which he would be expected to pay poetical tribute or on which he would have an opportunity to produce a poem of timely interest. *The Book of the Duchess* was such a poem, and what was probably his next long poem seems to have been begun with a similar purpose in mind. *The House of Fame* (1379?) superficially appears to be merely a humorous account of the poet's feelings and experiences in being carried by an eagle through the air, but in the beginning much is made of the fact that his life is so confined by his duties at the customs house and his habit of burying himself in books after his work at the office is done that he knows nothing of what is going on either at home or abroad, especially "tydynges of Loves folk." It is for this reason and because he has long served Cupid unrewarded that Jove has sent the eagle to transport him to where he will hear new things. After visiting the hall of the goddess Fame, he goes to the house of Rumor, where all kinds of reports, true and false, together with gossip and rumors of every sort, jostle one another. In the latter place he is making his way to a corner where "men of love-tydynges tolde" and where he sees "a man of gret auctorite." It is natural to expect an authoritative announcement of some sort, but with these words the poem breaks off in the middle of a sentence.

Whether the end of the poem is lost or whether the announcement to which it seems to be leading up was of something which failed to materialize we do not know. The poem is a mock epic, but its division into three books, each with its proem or invocation, and its account of a marvelous journey under the conduct of a knowing guide are reminiscent of the *Divine Comedy*; certainly the eagle was suggested by a passage in the *Purgatorio* (canto 9). The poem reveals signs of haste, and in it the poet expressly disclaims any intention of showing "art poetical," but in spite of obvious faults it remains one of the most self-revealing and delightful of the poet's works.

The Parlement of Foules (*The Parliament of Fowls*) was written probably in 1381, and the time of the action is St. Valentine's Day. Three royal or noble eagles present their suits to the beautiful female eagle that is perched on Dame

Nature's hand. All about are lesser birds of various classes. In the end the female eagle asks for a year in which to decide on her choice for a mate. The poem is most generally believed to represent under the guise of birds the preliminaries to a marriage between Richard II and Anne of Bohemia, sister of Wenceslaus, emperor of the Holy Roman Empire. The marriage took place January 14, 1382. The remarks and bickerings of the lesser birds are an amusing commentary on contemporary society, and the structure of the poem shows considerable improvement over that of *The House of Fame*.

Troilus and Criseyde is Chaucer's greatest artistic achievement. The tragic love story is an episode of the Trojan War and makes its first appearance in the 12th century French romance, the *Roman de Troie*, where it occupies intervals in the fighting. It was made the subject of Boccaccio's *Filostrato*, which was almost certainly one of the books Chaucer acquired on his second trip to Italy and which is the direct source of his poem. Chaucer's poem is by no means a slavish imitation. He took over only about a third of his original, so that a large part of the more than 8,000 lines of his poem is without direct parallel in his source. His most important debt to Boccaccio is for the theme and plot, and the outlines of the principal characters. But those characters he has in part altered and everywhere deepened; it is in characterization that the poem is especially distinguished.

Criseyde, young, beautiful, made to be loved, is a woman concerning whom men (and women) will probably always disagree. She is not a mere type, as are so many heroines of medieval romance, but a woman of great complexity, possessing strengths and weaknesses, and even her share of contradictions, so that she refuses to be neatly labeled and filed away in one's mind. In short, she is completely human. The poem has some of the qualities of the romance, but resembles even more the modern psychological novel. It could be thought of as a novel in verse. An unusual astronomical allusion in the third book indicates that Chaucer was working on it in 1385.

The translation of *De Consolatione Philosophiae* (*The Consolation of Philosophy*) by Boethius is thought to have been done shortly before the *Troilus* since its influence on the poem is quite clear. It is just as certain that *The Legend of Good Women* is later, because the *Troilus* is mentioned in it as one of Chaucer's poems at which the God of Love took offense. It consists of a lengthy prologue, at the end of which the god requires the poet to make amends by telling the stories of women who had suffered through loving faithfully. The number was apparently to be 20, forming a lectionary in which the martyrs were Cupid's saints. The poem is unfinished and breaks off in the course of the ninth legend. The prologue, much the most interesting part of the poem, exists in two very different forms. The revised form is pretty certainly to be assigned to some time after the death of Queen Anne, since the lines directing the poet to present it to her when finished are omitted. The earlier version was formerly dated 1386, but the grounds for this opinion have been shaken, and a more recent hypothesis identifies Alceste (Alcestis) with Joan, the "fair maid of Kent," widow of the Black Prince. Her sudden death in August 1385 would have been a sufficient reason for inter-

rupting work on the poem. The more usual explanation of its unfinished state is that Chaucer found writing about "good women"—good in the sense that they died for love—too monotonous.

Doubtless he had also thought of a better plan for a series of stories, the plan of the *Canterbury Tales*. The idea of tying together a collection of stories by means of a narrative framework, the "framed tale," is an old one. Examples are the story of the Seven Sages (the Seven Wise Masters), which Chaucer probably knew about, the *Decameron*, which he almost certainly did not know at first hand, *The Arabian Nights*, and in more recent times, the Sherlock Holmes tales and the Uncle Remus stories.

A religious pilgrimage offered one of the few opportunities in the Middle Ages for people of widely different social classes to associate with one another. Chaucer represents himself as falling in with a group of 29 other pilgrims about to make the trip to Canterbury and do their devotions at the shrine of St. Thomas à Becket. At the suggestion of Harry Bailly, keeper of the Tabard Inn, where the pilgrims assemble, they appoint him their guide and agree to tell stories as they ride along. Each pilgrim is to tell four stories, two each way. The collection would thus have consisted of 120 tales had Chaucer lived to complete it. Only 24 were ever written, and two of these are incomplete.

Those we have, however, constitute a veritable anthology of the principal types of medieval literature, and the general Prologue, in which he describes in detail those who made up the company, is one of the richest collections of "characters" (in the literary sense of the word) that we have in literature. Represented in the collection are the romance (*Knight's Tale*), the court romance, or Breton lai (*Franklin's Tale*), the fabliau (tales of the Miller, the Reeve, and others), the saint's legend (*Second Nun's Tale*), the beast fable (*Nun's Priest's Tale*), the exemplum, or moral apologue (*Pardoner's Tale*), the comedy (*Monk's Tale*), the classical legend (*Man of Law's Tale*), the sermon (*Parson's Tale*), and other lesser types.

There are some 80 manuscripts of the *Canterbury Tales*, including fragmentary ones, and they differ in both arrangement and detail. Chaucer evidently worked on different parts of the collection as ideas or materials came to hand, writing separate tales or small clusters of tales which he later intended to fit together into a well-integrated whole. This, as has been said above, he did not live to do. The manuscripts which we have represent the efforts of scribes, or what we would call editors or literary executors, to put together the material which they found. Consequently the order of tales differs in different manuscripts, and modern editors have to adopt an order which seems to them most nearly conform to Chaucer's intention so far as can be deduced from the internal and external evidence. Some of the tales are united by prologues and conversational or narrative links, thus establishing "groups" or "fragments" within the whole. Some of these groups may have been combined in a single copybook or bundle in Chaucer's desk. The place of others is indicated by references to the time of day or to towns along the route. But when use has been made of all these aids the result is not certainly that which Chaucer would have adopted.

On some matters Chaucer had probably not

made up his mind, and there is clear evidence that he changed his mind on certain points as he went along. The *Shipman's Tale* was originally intended for the Wife of Bath, and it has been suggested that the *Merchant's Tale* was written first for the Friar. By the time Chaucer began the *Parson's Tale*, he had given up hope of writing four tales for each pilgrim and was thinking in terms of only one tale apiece.

Within the general framework, Chaucer has employed certain specific devices to secure contrast, increase the realism, and heighten the dramatic effectiveness of the narrative. Thus, when he himself is called upon by the Host for a story, he begins to relate an extravagant parody of medieval romance; and when the Host rudely interrupts him and demands something more worth their while, Chaucer relates the serious (and to modern readers, dull) discussion between Melibeus and Dame Prudence, his wife. On another occasion, when the drunken Miller has told about a vulgar joke played on a carpenter, the Reeve, who earlier in life had been a carpenter by trade, insists on telling an equally vulgar story at the expense of a miller. The Wife of Bath, by her vigorous proclaiming of the philosophy that the wife should assert and maintain her mastery over her husband, starts a chain reaction in the course of which the Clerk answers her claims with the story of Patient Griselda, the Merchant presents another marital problem in his story of the old man who married a young wife and was cruelly duped by her, and the Franklin still another. Thus the interplay of character, the lively conversation between tales, and the high degree of appropriateness of most tales to the persons who tell them combine to make the *Canterbury Tales* a veritable *comédie humaine*.

We have several pictorial representations of Chaucer, drawn either from life or from memory shortly after his death. They agree fairly well in showing a man late in life, with a mustache and slight beard, short rather than tall, and somewhat portly. His face seems placid, even a little sad, but we can hardly doubt that in the prime of life it would have shown traces of the kindness, humor, and whimsicality which his poetry shows clearly were part of the man. He was a friendly spirit.

Bibliography.—Standard editions of Chaucer's works are those of W. W. Skeat, ed., *The Complete Works of Geoffrey Chaucer*, 7 vols. (Oxford 1894-97); id., *The Student's Chaucer* (New York 1895); A. W. Pollard, and others, eds., *The Globe Chaucer* (London 1898); Fred N. Robinson, ed., *The Complete Poetical Works of Chaucer* (Boston 1933).

Indispensable to the specialist is *The Text of the Canterbury Tales*, by J. M. Manly, Edith Rickert, and others, 8 vols. (Chicago 1940). There is Arthur G. Kennedy and J. S. P. Tatlock's *Concordance to the Complete Works of Geoffrey Chaucer and to the Roman of the Rose* (Washington 1927).

Good general treatments of the poet and his work are G. L. Kittredge's *Chaucer and His Poetry* (Cambridge, Mass., 1915); R. K. Root's *Poetry of Chaucer*, rev. ed. (Boston 1922); J. L. Lowes' *Geoffrey Chaucer and the Development of His Genius* (Boston 1934); H. R. Patch's *On Reading Chaucer* (Cambridge, Mass., 1939); P. Van D. Shelly's *Living Chaucer* (Philadelphia 1940); J. S. P. Tatlock's *Mind and Art of Chaucer* (Syracuse 1950). An interesting popular biography is Marchette G. Chute's *Geoffrey Chaucer of England* (New York 1946).

The publications of the Chaucer Society include many volumes of texts and studies, among them *Life Records of Chaucer*, 2d series, nos. 12, 14, 21, and 32 (London 1875-1900).

ALBERT C. BAUGH,
Department of English Language and Literature,
University of Pennsylvania

CHAUCHAT, shō-shā', **Jacques Louis Henri**, French army officer and firearms inventor: b. Paris, 1863; d. there, 1927. A graduate of the Ecole Polytechnique in 1885, he became an artilleryman, and from 1895 specialized as a technician in arms manufacture. Promoted major in 1905, he became a colonel in 1915. The automatic rifle called Chauchat-Sutter, which he invented in collaboration with two other technicians, passed ordnance tests in 1913, and mass production began soon after the outbreak of World War I. The Chauchat was first used effectively in the battle of the Somme in 1916. It was adopted by the American Army.

CHAUDIERE, shō-dyār', river, Canada, which has its rise in Maine, near the source of the Kennebec, and flows north for 120 miles and joins the St. Lawrence about six miles above Quebec. Between two and three miles above its mouth it forms the Chaudière Falls.

CHAUDIERE FALLS, Canada, in the Ottawa River, just above the city of Ottawa. Here the river narrows to about 200 feet and then descends 50 feet, forming the falls.

CHAUFFEUR, shō-fēr' (Fr. a "stoker"). This term has recently come into use in the English language to designate at first the engineer or motorman of a steam-driven road carriage; but by extension it is now applied to any professional machinist who operates an automobile, electrically or otherwise propelled. During the Reign of Terror in France the word was applied to members of a band of outlaws who infested the northeastern portion of the kingdom. They were led by John the Skinner. They garroted men and women and tortured others in efforts to make them disclose hidden treasure. The band was not suppressed until 1803.

CHAULIAC, shō-lyak', **Guy de**, French surgeon: b. Gévaudan (modern Lozère), c.1300; d. probably Avignon, c.1370. He practised his profession at Lyon, then at Avignon, where he was physician to three popes: Clement VI, Innocent VI, and Urban V (1342-1370). There in 1343 he composed his great work, *Inventorium sive Collectarium Partis Chirurgicæ Medicinæ*, translated into French by Laurent Joubert in 1592 under the title *Grande Chirurgie*. It was a standard manual from the 14th to the 17th centuries.

CHAULMOOGRA, chōl-mōō'grā, or **CHAULMUGRA** (*Taraktagenos kurzii*), a tree of the order Flacourtiaceæ which grows in eastern countries and from the seeds of which is obtained an oil that is valued in China and elsewhere as a remedy for certain skin diseases.

CHAUMETTE, shō-mēt', **Pierre Gaspard**, French revolutionist: b. Nevers, France, 1763; d. April 13, 1794. In early life he wandered over France and became interested in botanical studies and was studying medicine at Paris at the outbreak of the revolution and for a year following. He contributed anonymously to the *Révolution de Paris*. He became a member of the insurrectionary commune, by which in 1792 he was made delegate to visit the prisons with power to arrest suspected persons. He acquired great influence in Paris and was made president of the Commune.

In 1793 he was one of the leaders in the attacks against the Girondists, whom he treated with great harshness. Opposing Robespierre in an effort to save the Hébertists he was overthrown by the latter, who had him arrested. He was tried by the Revolutionary Tribunal and executed. He left some speeches and memoirs.

CHAUMONOT, shō-mō-nō', **Pierre Marie Joseph**, French missionary: b. Burgundy, France, March 6, 1611; d. Quebec, Feb. 21, 1693. His father was a vine dresser who committed the care of his son to his brother, who was curé at Châtillon. Pierre ran away at the age of 10 in order to study music at Beaune, Burgundy. In the course of a pilgrimage to Rome he came under the notice of the Jesuits, who induced him to become a member of their order and sent him as missionary to the Indians of Canada in 1639. He was first assigned to the Huron missions at Ossossane, where he collected material for a Huron dictionary. In 1640 he accompanied Jean de Brébeuf to a tribe living between Lake Erie and Lake Ontario and to the west of the dreaded Iroquois. This mission resulting in failure, Chaumonot went to St. Michel de Laval where he remained eight years until the settlement was destroyed by the Iroquois. Chaumonot then took the surviving Hurons to an island in Lake Huron and later to the Island of Orleans where he served as a spiritual leader for 35 years except for short absences. In 1692 he retired to Quebec, where he died.

His Huron grammar was translated into English and was published in *Transactions* of the Library and Historical Society of Quebec in 1831.

Consult his autobiography published in New York in 1658.

CHAUMONT, shō-môn', commune, France, the capital of the Department of Haute-Marne, on a height between the Marne and the Suize, 140 miles southeast of Paris by rail. It is well built, has a fine town hall, courthouse, communal college, public library, church dating from the 13th century, the ruins of a castle belonging to the counts of Champagne, and an iron bridge 1,960 feet long with 50 arches on which the railway crosses the Suize. There are manufactures of gloves, wax candles, hosiery, cotton, cutlery, leather, woolens, sugar, etc.; and a trade in grain, coal and in the iron and iron goods of the department. At Chaumont, in March 1814, was signed a treaty between Great Britain, Russia, Austria, and Prussia, in which these powers pledged themselves to accomplish the overthrow of Napoleon and restore peace to Europe. Philippe le Bon, the first who advocated the use of gas for illumination, in France, was a native. Chaumont was the headquarters of the American Expeditionary Forces under General Pershing during World War I. Pop. (1946) 15,068.

CHAUNCEY, chón'sī, **Isaac**, American commodore: b. Black Rock, Conn., Feb. 20, 1772; d. Washington, D.C., Jan. 27, 1840. He commenced his career in the merchant service, in which he became distinguished for seamanship, enterprise and energy. He entered the navy as lieutenant in 1799, and early in 1802 was appointed acting captain of the frigate *Chesapeake*, the flagship of a squadron ordered to the Mediterranean.

operate against Tripoli. In the brilliant operations before Tripoli in 1804 he bore a distinguished part. In April 1806 he was promoted to the rank of captain. In the War of 1812 the naval superiority on the lakes became an object of high importance, and Commodore Chauncey, then in command of the navy yard at Brooklyn, was appointed to command on Lakes Ontario and Erie. He commanded the Mediterranean squadron in 1816-1818 and negotiated the treaty of peace with Algiers. From 1821 to 1824, and again from 1832 to 1840, he was navy commissioner in Washington, D.C., where he remained until his death.

CHAUNCY, Charles, American clergyman and educator: b. Yardley-bury, Herts, England, bap. Nov. 5, 1592; d. Cambridge, Mass., Feb. 19, 1672. Educated at Westminster School and at Trinity College, Cambridge, he became a fellow of Trinity (1614) and professor of Greek (1624 and 1626). As a vicar of the Church of England he was twice summoned before ecclesiastical commissions and once imprisoned for his criticism of the church, submitting each time and each time regretting his submission. In 1638 he fled to New England, where he preached in Plymouth for three years, and was then pastor at Scituate, where again he was in conflict with the established church. In 1654 he was chosen to be the second president of Harvard College, with the understanding that he would not preach his unorthodox doctrines; he retained the post until his death. Many volumes of his sermons and doctrines were published.

His great-grandson **CHARLES CHAUNCY** (b. Boston, Mass., Jan. 1, 1705; d. there, Feb. 10, 1787), also a clergyman, was a liberal leader of his time. He received a master's degree from Harvard in 1724 and became pastor of the First Church, Boston, in 1727, serving it for 60 years as one of the most influential Congregational ministers in New England. He denounced the excesses of the "Great Awakening" (q.v.), the religious revival that swept New England in 1740-1745, vigorously assailing both its leading protagonists, Jonathan Edwards and George Whitefield. Chauncy stood against Episcopacy, opposing attempts to impose the Church of England system upon the American dependencies, and supported the colonists in the War of Independence.

CHAUNY, shō-nē', commune, France, Department of the Aisne, on the Oise River and the Oise-Sambre Canal, 16 miles southwest of Saint-Quentin. Completely destroyed in World War I, when it changed hands four times, it was rebuilt, but was again damaged in 1940. An industrial town, it has foundries, wire and glass works, chemical factories, and sugar refineries. It was once an important market town. Pop. (1946) 9,206.

CHAUS. See **JUNGLE CAT** OR **CHAUS**.

CHAUTAUQUA LAKE, shá-tó'kwá, a beautiful lake situated in Chautauqua County, New York. The name comes from a Seneca Indian phrase meaning "one has taken out fish there." The lake is 18 miles long and from one to three miles wide, 730 feet higher than Lake Erie and 1,300 feet above sea level. On its bank is the town of Chautauqua.

CHAUTAUQUA MOVEMENT, an influential and characteristically American development in adult education, originated in 1874 with the first Chautauqua Assembly, held on the shores of Chautauqua Lake in the southwestern corner of New York State. The original assembly, since 1902 incorporated as Chautauqua Institution, continues to flourish at Chautauqua, N. Y., providing an eight-week summer program of lectures, music, operas, and plays, and offering summer school courses (carrying university credit) in education, music, and other fields.

The idea of utilizing the summer vacation for educational purposes was the most distinctive contribution of Chautauqua to American education. Such was the prestige of the original Chautauqua that its name was borrowed by a multitude of "circuit" or traveling chautauquas, which flourished in the first quarter of the 20th century, presenting three-day or one-week programs of popular lectures and entertainments in tents in thousands of American communities, particularly in the Middle West. The original Chautauqua Assembly also pioneered in developing home reading courses, correspondence study, and university extension lecturing, thus giving an early impetus to the kinds of adult education now being carried on by libraries, extension divisions of universities, and various agencies providing formal instruction by correspondence.

The founders of the Chautauqua movement were Lewis Miller, an Akron, Ohio, manufacturer, and Dr. (later Bishop) John Heyl Vincent, a Methodist minister, both of whom had long been active in the Sunday school movement. Together they devised a plan for offering intensive training to Sunday school teachers by scheduling a conference for them during the summer vacation, when more would be free to attend. Recreation was to be combined with education through the choice of an appropriate woodland spot. The result was the Chautauqua Lake Sunday School Assembly, which met for its first season from August 4 to 18, 1874.

The Chautauqua Assembly immediately attracted nationwide attention, and its program was rapidly enlarged in subsequent years. The session was lengthened to eight weeks, embracing most of July and August. Though biblical and religious topics dominated the first assembly, public affairs received increasing attention year by year, and national leaders began to speak regularly from the platform. By the 1880's Chautauqua had established itself as a national forum for the discussion of ideas and issues in politics, international relations, economics, literature, and science, as well as religion. This leadership in the making of an informed public opinion continues. No less than seven presidents of the United States, from Ulysses S. Grant to Franklin D. Roosevelt, have visited Chautauqua, often to deliver important addresses on national policy in the great amphitheater, constructed in 1893 and seating some 6,000.

Following World War I the musical program came to rival the lecture offerings in significance. A full season of orchestral music has constituted part of the program since 1920, and the Chautauqua Symphony Orchestra has been frequently heard on nationwide broadcasts. Presentations of opera began in 1926, and in 1929 Norton Memorial Hall provided adequate facilities for regular seasons by the Opera Association and the Repertory Theater. Chamber music, choral

performances, concerts by vocal and instrumental soloists, and organ recitals also figured among the offerings.

The formal educational work of Chautauqua developed as rapidly as the public lecture program, achieving its widest scope and variety in the 1880's and 1890's. The greatest educational innovation was formal classroom instruction in the summer, which had not been attempted in any significant way until Chautauqua inaugurated it in 1874. Language study began in 1875, courses in pedagogy quickly followed, and work in the standard fields of literature, history, and science was regularly offered. A second important innovation was instruction by correspondence, which began in 1881, preceded by only a few experiments in other institutions. University extension lectures, developed in England, were introduced to America in the 1880's, with Chautauqua among the first to offer them, in 1889.

These varied educational activities added up to the equivalent of a complete collegiate program, and the Chautauqua University was chartered in 1883, with power to grant degrees. This power was sparingly used and was surrendered in 1898, the title university having already been dropped. The Chautauqua Summer Schools continued (but neither correspondence study nor extension lecturing), and they continued to offer university credit, through administrative affiliation with an established university (for a long period, New York University; more recently, Syracuse University).

In keeping with the principle enunciated by Dr. Vincent, that "mental development is only begun in school and college, and should be continued through all of life," Chautauqua inaugurated in 1878 a program of directed home reading, which reached vast numbers of Americans who never attended the programs at Chautauqua itself. The original aim was to bring to men and women who had been deprived of the opportunity for higher education "the college student's general outlook upon the world and life." A carefully selected group of books for a year's reading was provided, together with guides and supplementary articles, the latter being eventually published in a monthly magazine, *The Chautauquan* (1880-1914). Encouragement was given to the organization of local reading circles, of which approximately 10,000 were eventually formed, three quarters of them in communities under 3,500 population. The Chautauqua Literary and Scientific Circle has given diplomas for the satisfactory completion of four consecutive years of such directed reading, and approximately 75,000 persons have qualified, out of several hundred thousand readers who have enrolled at one time or another.

The success of the program at Chautauqua, N. Y., inspired persons in many communities throughout the country to organize local chautauqua assemblies, of which more than 30 had come into existence by 1886. These were, for the most part, faithful imitations on a small scale of the original Chautauqua, and they seem to have preserved that character well into the 1890's, though not affiliated with the original institution. As the number of such chautauquas increased, however, commercialism dominated the picture. After 1900 the programs tended to be of an extremely popular sort, with political oratory, inspirational lectures (of the "hearth, home, heaven" variety), and musical entertainments as the staple features. "Talent" was usually supplied by

commercial lecture bureaus, and the most enterprising of these developed the "circuit" or traveling chautauquas or camp meetings, which toured the country during the summer with their own tents, equipment, speakers, and entertainers, making three-day or one-week stands in communities which signed up in advance. Many prominent politicians found the circuit chautauqua a convenient vehicle for campaigning, and all but the crassest programs doubtless brought a good deal of cultural stimulation to small communities whose isolation was great in the days before the motion picture, the automobile, and the radio. These inventions doomed the old-time local chautauquas. Their heyday came just before World War I, decline was rapid in the 1920's, and the depression of 1929 seems to have wiped out the last of the circuits.

Chautauqua Institution, however, has adapted itself with remarkable resilience to changing social forces. Its program has always been and continues to be alive to major contemporary issues. The depression brought serious financial problems (including a temporary receivership in 1933), but these were solved without interruption of any part of its program. Chautauqua emerged from the crisis of the 1930's in a stronger position than before, with all obligations met and a substantial new endowment.

That Chautauqua has maintained a position of leadership in public opinion and adult education throughout 80 years of rapid change is evidence of the creative thinking of the men who have directed its activities. The two founders guided the movement during its formative period, and brought into association with them such distinguished educators as Dr. William Rainey Harper, who was principal of the Chautauqua Summer Schools, 1887-1898, and who incorporated many ideas derived from Chautauqua into the structure of the new University of Chicago where he became its first president in 1891. He was succeeded as principal of instruction by Dr. George E. Vincent, son of one of the founders, who was president of Chautauqua Institution from 1907 until 1915, when his duties as president of the University of Minnesota and later of the Rockefeller Foundation compelled him to retire from the active leadership of Chautauqua. His successor, Dr. Arthur E. Bestor, became associated with the Institution in 1905, and was its president from 1915 until his death in 1944. His administration, spanning two world wars and a great depression, carried Chautauqua through perhaps its most critical period of readjustment and re-evaluation, and insured its continued pre-eminence as a forum of public discussion and a center of cultural activity in the mid-20th century. Since his death the program has been under the direction of Ralph McCallister.

Part of the strength of Chautauqua lies in the fact that it is a community as well as an educational institution. Though the permanent population is small, some 8,000 to 10,000 persons make Chautauqua, N. Y., their summer home, and approximately 40,000 attend some part of the season's program. Chautauqua Institution is incorporated by special act of the New York state legislature as a non-profit educational institution under a board of trustees. The Institution conducts the program of lectures, music, and school; with funds derived from admission charges at the gate, school registration fees, endowment, and miscellaneous income. It also maintains the edu-

cational plant and furnishes many of the municipal services of the community.

ARTHUR E. BESTOR, JR.,
Professor of History, University of Illinois.

CHAUTEMPS, shō-tàn', Camille, French political leader: b. Paris, France, Feb. 1, 1885. Leader of the Radical Socialists, he was minister of the interior in 1924 and of justice 1925-26, and in February 1930 became premier of France, a position he was to hold twice more during the stormy years leading up to World War II. After serving as minister of public instruction (1931) and of the interior (1932-1933) he again became premier, serving from November 1933 to January 1934. He was minister of public works during the first half of 1936, then minister of state (1936-1937) in the first government of Léon Blum, and, for the third time, premier (June 1937 to March 1938). He resigned upon Germany's annexation of Austria, but continued as vice premier until June 1940, serving in the cabinets of Édouard Daladier and Paul Reynaud.

Following the collapse of France, Chautemps sided with Marshal Henri Philippe Pétain, served in his cabinet, and represented the Vichy government on a secret mission to the United States in November 1940. At the end of the war the French High Court tried him in absentia, convicted him of collaboration, and in March 1947 sentenced him to five years in prison. In April 1954—the statute of limitations having voided his sentence—he returned to Paris after 14 years in the United States.

CHAUVEAU, shō-vō', Pierre Joseph Olivier, Canadian politician and writer: b. Quebec, Canada, May 30, 1820; d. there, April 4, 1890. Educated at Quebec Seminary, he was called to the bar in 1841, becoming a Queen's Counsel in 1853. He entered Parliament in 1844 and held portfolios in the government until 1855 when he was appointed chief superintendent of public instruction for Lower Canada. In 1857 he founded the *Journal of Public Instruction* (also published in French). He was first premier of the Province of Quebec under the Confederation (1867-1873), and speaker of the Senate (1873-1874). In 1878 he became professor of Roman law at Laval University, Montreal, later dean of the law faculty.

CHAUVEAU-LAGARDE, -là-gård', Claude François, French advocate: b. Chartres, France, 1756; d. Paris, 1841. During the French Revolution he became celebrated for his eloquent defense of those on trial in the Reign of Terror, when he was himself imprisoned for a short time. He was the advocate of Marie Antoinette and of Charlotte Corday at their trials. He defended Jacques Pierre Brissot and Madame Elizabeth of France; his defense of the Venezuelan general

Francisco Miranda saved him from the scaffold. In 1814 he was ennobled by the government of the Restoration, and in 1828 appointed counselor to the Court of Cassation.

CHAUVINISM, shō'vîn-iz'm, a word derived from Nicolas Chauvin, a soldier of the French Republic and the First Empire. His excessive admiration for Napoleon made him an object of ridicule among his comrades, so that the word coined from his name became a synonym for those who show exaggerated devotion to any extreme form of patriotism. A vaudeville piece, *La cocarde tricolore* (1831), in which there was a character named Chauvin and a song that became immensely popular, fixed the word in the French language. It is now used not only in French but in English and other languages to express over-intense nationalism such as jingoism.

CHAVASSE, shā-vās', Francis James, Church of England prelate: b. Sutton Coldfield, England, Sept. 27, 1846; d. Oxford, March 11, 1928. Educated at Corpus Christi College, Oxford, he was ordained in 1870. As bishop of Liverpool from 1900 to 1923, he is best remembered for his services in starting construction of Liverpool Cathedral, designed by Sir Giles Gilbert Scott.

CHAVES, shā'vēsh (Lat. AQUAE FLAVIAE), town, northern Portugal, in the Vila Real district of Trás-os-Montes e Alto Douro Province, on the Tâmega River 22 miles north-northeast of Vila Real. Its name means "keys." It is a center for agricultural trade, and manufactures textiles, chocolates, and ceramics. Its hot mineral springs gave it the ancient Roman name. Situated eight miles from the Spanish border, it figured frequently in conflicts between the two countries. Changing hands many times down the centuries, it played a part in the Peninsular War when Napoleon's Marshal Nicolas Jean de Dieu Soult captured it March 12, 1809. It was often used as a meeting place to settle disputes, notably on Sept. 18, 1837, when the monarchists and liberals met at the Convention of Chaves. Pop. (1940) 8,706.

CHAVEZ, chā'vās, Carlos, Mexican orchestral director and composer: b. Mexico City, June 13, 1899. Except for piano lessons from his brother Manuel and a few lessons later from Mexican teachers, he was largely self-taught, learning from books and from the music of European masters. He traveled in Germany, France, and the United States, broadening his horizon. His first work incorporating Mexican folk music was a ballet, *The New Fire* (1921), commissioned by the secretary of education. In 1928 he founded the National Symphony Orchestra of Mexico City and became director of the National Conservatory of Music, and in 1933 headed the Department of Fine Arts, where he used his influence to encourage native composers to use Indian sources for their music. In 1931 his *Energía* was played at a Pan American concert in Paris. The following year his ballet-symphony *H.P.* (horsepower) with stage design by Diego Rivera was produced by the Philadelphia Grand Opera Company directed by Leopold Stokowski. *Sinfonia India* was first heard over the Columbia Broadcasting System in 1936. It employed Indian instruments seldom heard in symphonic music. He

visited the United States many times as guest conductor of leading orchestras. In 1938 he received a Guggenheim fellowship. The *Concerto for Four Horns* and the piano concerto (first heard in New York in 1942) gave evidence that Chávez was a craftsman of high musical intelligence who succeeded in incorporating new forms into common speech while giving lofty expression to the musical ideology of his people. His views on music are given in his book *Toward a New Music* (Eng. tr., New York 1937).

CHAY, chā, or **CHOY**, the root of a small plant, common in Hindustan, which yields a durable red dye.

CHAYOTE. See **SECHIUM**.

CHAZYAN, in *geology* the second series of the Ordovician System of North America, succeeding the Canadian and underlying the Bolarian or Lower Mohawkian. This series is named after Chazy, a town in northeastern New York State where there are about 1,000 feet of fossiliferous limestone; equivalent shales have Llanvirnian and Llandeilan graptolites. See also **ORDOVICIAN**.

CHEAPSIDE, historical London district and street of London, England, extending eastward from St. Paul's Cathedral to Poultry, and thence to the Mansion House. In the Middle Ages the Chepe (from the Anglo-Saxon word *ceap*, sale or bargain) was an open square where markets and fairs were held, and executions occasionally took place. In this section were two of the Eleanor Crosses (q.v.), and here also stood the famous Mermaid Tavern, convivial gathering place of William Shakespeare, Ben Jonson, and other poets and dramatists of their day. John Milton was born in this area. After the Great Fire of 1666, the square was narrowed down to one street. During World War II Cheapside was heavily bombed.

CHEAT, chēt, river, rising in the Allegheny Mountains in West Virginia, and after the union of its forks flowing north and northwest into the Monongahela River at Point Marion, a few miles over the Pennsylvania border. About 75 miles long, it is a source of hydroelectric power, being dammed in its lower course to form the 10-mile-long Cheat Lake, or Lake Lynn. At the West Virginia end the river has carved a gorge with walls 1,000 feet high, a scenic area made part of the Coopers Rock State Forest.

CHEAT. See **BROME GRASS**.

CHEATHAM, chēt'ām, Kitty (in full **CATHERINE SMILEY BUGGE**), American soprano: b. Nashville, Tenn., 1864?; d. Greenwich, Conn., Jan. 5, 1946. She studied music in France and Germany and was the first singer to introduce Negro songs to Europe. An interpreter of the literature and songs of childhood, she appeared in concert halls throughout the United States and Europe with a repertoire that included more than 1,000 songs in nine languages, with special emphasis on the works of American composers.

CHEB, kěp (Ger. **EGER**), town, Czechoslovakia, in the Province of Bohemia, on the Ohře River, 90 miles west of Prague (Czech **PRAHA**), near the German border. A rail junction and

industrial center, it manufactures motorcycles, bicycles, agricultural machinery, textiles, leather, and beer. Peat is cut nearby. The Austrian general Albrecht von Wallenstein, prince of Sagan, was assassinated here in 1634. In 1933 the majority of the German population began to leave, anticipating trouble, and after World War II the remainder were sent away. Pop. (1947) 14,533.

CHEBOYGAN, shē-boi'gān (an Indian name meaning "place of entrance"), city, Michigan, seat of Cheboygan County. At an altitude of 600 feet, it lies at the mouth of the Cheboygan River on the South Channel of the Strait of Mackinac on Lake Huron. It has an airport. Once an important lumbering center, it now manufactures paper and other wood products, snow plows and tools. Having excellent port facilities, it ships fish and agricultural products. A leading summer and winter resort, it is headquarters for fishermen, and here begins an inland water route by canoe, much used by sportsmen. Pop. (1950) 5,687.

CHECHEN-INGUSH, chī-chēn'in-gōōsh', former Autonomous Soviet Socialist Republic, formed in 1920 of two autonomous oblasts within the Russian Soviet Federated Socialist Republic. The Chechen-Ingush ASSR occupied 6,100 square miles on the north slopes of the Caucasus. The area is rich in oil and timber, Grozny, its chief city, being one of the principal oil-producing centers of the USSR. Population in 1941 was estimated at 732,838, about 55 per cent Chechen and 10 per cent Ingush, both groups of Mohammedan religion. For generations the Chechen people had fought the Russians fiercely, especially in the struggles led by Shamyl (q.v.) or Shamil during the first half of the 19th century. In 1944 the Soviet government dissolved the Chechen-Ingush ASSR, on the ground that many Chechens had collaborated with the German invaders in World War II and had set up saboteur groups in the rear of the Soviet troops. As a result the population was resettled in other districts of the Soviet Union.

CHECK. See **COMMERCIAL PAPER**.

CHECKERBERRY. See **GAULTHERIA**.

CHECKERED BEETLE, any member of the Coleopterous family Cleridae, which are often marked or checked with red, yellow, and other shades and often with the dark portions metallic bluish-green, or purple. The larvae are predaceous, free running. They are found in the soil in the nests of bees and wasps and in the egg capsules of grasshoppers; above ground in the nests of bees and wasps, and under bark where they feed upon boring insects. The adults are also predaceous and are particularly beneficial in destroying bark beetles (q.v.). Some species visit flowers to feed upon pollen and nectar.

CHECKERS or **DRAUGHTS**, drafts, a game for two opponents, played upon a square board marked in 64 small squares of alternating colors in 8 rows of 8 each. Each contestant has 12 checkers at the beginning, all of them governed in their moves by the same rights and restrictions. Because of the points of similarity and difference between checkers and chess (q.v.), the

two games are often compared. There are conflicting boasts about the age of the two games and the number of players of each. Some authorities on checkers hold that their game requires so much less original explanation that it may have lived a long time before chess was developed into approximately its modern form. Some insist checkers is over 5,000 years old.

Though checker partisans maintain that there are many more players of their game than of chess, they admit that claim may be justified only by counting the players of variants from the form best known in America, Britain, and France such as Spanish draughts, Polish draughts, Italian draughts, German draughts, Turkish draughts, and other games, each with somewhat different rules from American checkers.

What Americans think of as American checkers and the British call English draughts, played throughout the English-speaking world, has by far the largest number of players among the various forms of checkers. As in other forms of the game, all of the play is on half the squares of the board, usually the darker squares. The board is so placed that a single black square is in the corner at the left of each contestant. For greater ease in recording moves, reporting games, and presenting problems, standard diagrams of the board reverse the color scheme, making it possible to use type in numbering the squares as in the accompanying diagram.

BLACK			
1	2	3	4
5	6	7	8
9	10	11	12
13	14	15	16
17	18	19	20
21	22	23	24
25	26	27	28
29	30	31	32
WHITE			

The checkers, in the form of disks a bit smaller than the squares, are placed on the squares numbered from 1 to 12 inclusive for the player of the Black or darker men, and on those numbered 13 to 32 for the player of the White or lighter men. Black always moves first, and thereafter the players alternate. All moves are diagonal, and all of just one square except when capturing an opposing piece or pieces. Whenever a man reaches the "king row"—the row farthest from where it began—it is crowned by placing another checker of the same color on top of it. In subsequent moves, such a man, called a "king," may jump forward or backward or in a series combining both directions, or make plain moves in either direction; whereas a man that is not a king may move only forward, or away from its player. Whenever a player is able to jump one of his men over an opposing man on the diagonally adjoining square onto an unoccupied square, he must do so, thus capturing the jumped man, which is then removed from the board. It is possible, in certain positions, for a man to jump a series of opposing men, the maximum possible being 9 by a king, though this seldom occurs. If a player is in position to jump in more than

one direction with more than one of his men, he may choose any jump or series of jumps he prefers, regardless of which will jump the larger number of men in series, but he must complete the available series of jumps in the path he selects. If a player fails to jump, when able to, and attempts a plain move instead, he is required under the laws of the American Checker Federation to take back the plain move, and jump. When a plain man jumps into the king row and is crowned, its move ends there; it may not on the same move jump another piece. The objective of the game is to produce a situation in which it is impossible for one's opponent to make a move, usually because all his men have been captured or cornered. A draw results when it develops that neither side can force a win. Among ranking players there are many draws, among lesser, few.

Perhaps half of all checker games are for the casual recreation of the participants, the overwhelming majority of these, people who have never read a book on the game or made a serious study of it. The better players are as deep students as those of any other intellectual pastime, and the literature of the game is rich in guidance as to opening series of moves, general mid-game strategy and end-game tactics, besides special treatises on maneuvers which experts call traps, tricks, and shots; collections of problems, and compendiums of records of famous games.

Tournament and match play competitions on a national basis have been conducted in England and Scotland for nearly two centuries. Such formal events in or between clubs, schools, and other organizations have been numerous in the United States, where the first national championship was played in Boston in 1905. In the early 1950's, under the auspices of the American Checker Federation, there were four recognized world championships at match play, all of them held by Americans, each of them subject to a challenge match every two years. Tom Wiswell, of Brooklyn, N. Y., won that based on the straight game of checkers, called the world "go-as-you-please" championship, defeating a fellow Brooklynite, Millard Hopper, in 1951. The "three-move" world championship was successfully defended in the same year by Walter Hellman, of Gary, Ind., against Maurice Chamblee of Birmingham, Ala.; in this event the first two moves of Black and the first of White are prescribed for each game, these obligatory moves being determined in advance by ballot. A similar event, the "two-move" championship, was won in 1952 by Marion Tinsley of Columbus, Ohio, over Newell Banks of Detroit, Mich., known as "the grand old man of checkers," who holds the "blindfold" championship and has been a champion at various forms of checkers for many years.

Bibliography.—Wiswell, T., *Learn Checkers Fast* (New York 1946); Ryan, W. F., *Tricks, Traps and Shots of the Checkerboard* (New York 1950); Wiswell, T., and Hopper, M. F., *Checker Kings in Action* (New York 1952); Evans, L., and Wiswell, T., *Championship Chess and Checkers for All* (New York 1953).

SHEPARD BARCLAY.

CHECKOFF, a practice whereby an employer by agreement with a union withholds from members' pay their dues, fees, and assessments, and transmits funds withheld to the union. The Taft-Hartley Labor Act required that before an employer might withhold funds from wages, each employee must authorize the checkoff by written

assignment, irrevocable for one year or until the contract expires, whichever is shorter. If an "escape period" is provided, checkoff authorizations may be renewed automatically from year to year. A Bureau of Labor Statistics survey of 1,653 contracts (covering 5.5 million workers) in 1952 revealed that 71 per cent provided the checkoff, 31 per cent covered initiation fees as well as dues, and 20 per cent also included checkoff of assessments. The checkoff was found in nine tenths of the agreements having no union shop or maintenance-of-membership, but only in slightly over 60 per cent of those granting union security; it was found in over 90 per cent of Congress of Industrial Organizations (CIO) and independent union contracts but in only 50 per cent of American Federation of Labor (AFL) agreements. All contracts studied in the communications industry had checkoff clauses but few had union security; in the construction industry, the opposite was found to prevail.

JOHN NEWTON THURBER,

Formerly, United States Department of Labor.

CHECKS AND BALANCES, a term signifying the method adopted by the framers of the Constitution of the United States to separate the powers of government so as to prevent the encroachment by one branch upon the domains of the others. Hence in organizing the national government, the Constitution provided that all bills, before becoming laws, must be passed by both branches of Congress, thereby in effect giving each house the right to veto or disapprove the acts of the other. Thus were the House of Representatives and the Senate balanced against each other. However, the Constitution further provides that before a bill passed by the Congress can become a law it must be submitted to the president who must either sign (approve) it or return it to the House in which it originated together with a statement of his objections. Thereafter the Congress may repass the bill by a two-thirds vote of each house, in which event it becomes a law just as though it bore the president's signature. This is what is known in parliamentary language as "overriding the president's veto." The veto power is the president's check upon Congress, and the right to pass a measure over the veto (but only by a two-thirds majority) is Congress' check on the president.

Again the judicial department is balanced against both the executive and the legislative by the power it has assumed of refusing to sanction the acts of either when it regards such acts as having been done without authority, that is, in contravention of the Constitution. The legislature is balanced against both the judiciary and the executive by giving it the right to impeach and remove executive and judicial officers from office for high crimes and misdemeanors. The Senate is balanced against the executive by requiring its approval of treaties negotiated at the behest of the president, and also by requiring its consent to most if not all executive appointments such as ambassadors, ministers, consuls, judges of the Supreme Court, and numerous others. Treaties require approval by two thirds of the Senate to become effective. Many other examples of checks and balances might be given. State constitutions have followed the example of the national Constitution in providing checks and balances in the conduct of the internal affairs of states.

CHECKS AND DRAFTS. A check is the simplest form of bank draft; that is, a check is a written order by a bank's customer to pay a specified amount of money from the customer's checking (demand) account to a designated third party. A bank draft may be defined as an official check drawn by a bank against funds it has on deposit with another bank, or an arrangement made between the buyer and seller of goods and services for payment of an agreed amount on delivery or performance.

For example: a flour mill in Buffalo, N. Y., buying wheat from an elevator company in Kansas, agrees to pay for the wheat on delivery. When the seller ships the wheat, he draws a draft on the Buffalo flour mill for the agreed amount; and after attaching the railroad bills of lading to it, takes it to his own Kansas bank for collection. The Kansas bank forwards the draft with attached bills of lading to a bank in Buffalo. The collection department presents the draft to the flour mill and when payment is made delivers the draft and bills of lading to the flour mill. The money collected, except for a small collection fee, is sent to the Kansas elevator firm. This is only one illustration of the uses made of drafts in business transactions.

A simple illustration of the use of checks would be: John Doe has \$150 on deposit in a checking account at the State Central Bank, a sum which he desires to use for the purchase of a washing machine from the Home Appliance Store. He buys the machine for \$125 and draws a check or order for his bank to pay the store that amount from his account. The appliance store may not be a customer of the State Central Bank but may deposit John Doe's check at the Town National Bank, through the local clearing house; and the check is delivered to the State Central Bank where \$125 is deducted from the account of John Doe.

A check written on an account in a city or town anywhere in the United States can be paid in any other part of the United States and many foreign countries. It will be returned to the bank on which it is drawn, through a remarkably efficient check-collecting service maintained by the Federal Reserve System.

The committee on collections of the Federal Reserve System and the American Bankers Association have cooperated for many years in a program to improve the efficiency of the countrywide collection of checks. One step in that program was taken in 1910, when all banks in the United States were numbered to indicate their name and location. This is a hyphenated symbol, as "2-1." The figure 2 would show the bank is located in the central reserve city of Chicago, and the 1 would identify the First National Bank of Chicago.

Another step in this program was taken in 1949, when a check-routing symbol was assigned to each bank whose checks are collectible through the Federal Reserve System. This routing symbol appears with the transit number, and the combined symbol is printed in the form of a fraction in the upper right hand corner of checks, just above the figure amount line. For example: 55-14611-2-4.

The denominator or the lower figure is the routing symbol, composed of three or four digits without spacing. The first digit (or two in the case of Kansas City, Dallas, and San Francisco) designates the Federal Reserve dis-

trict in which the bank is located. The second digit designates the Federal Reserve bank or branch serving the drawee bank. The third digit indicates the number of days that elapse before the item can be cleared and presented for payment at the drawee bank.

Checks are useful in making all kinds of payments, because they can be transferred from one party to another like money. The payee of a check transfers ownership by writing his name on the back of the check exactly as it appears on the face. By endorsements, checks may pass through several hands before being finally paid at the bank on which they are drawn. The three most common forms of endorsement are: blank endorsement, which consists of the signature of the endorser only, as "John Brown"; a special endorsement specifying the name of the person or firm to whom the check is being transferred as:

Pay to the order of
William Green
John Brown;

a restrictive endorsement preventing further transfer of a check by specifying the only purpose for which the check can be used; for example:

Pay to the order of
State Central Bank
For Deposit only
John Brown.

A check is usually about $8\frac{1}{4}$ inches by $3\frac{1}{8}$ inches and a common arrangement is:

FARMERS AND MERCHANTS STATE BANK		NO. _____
NEWTON, MASS. _____ 19 _____		PS-1378 1041
Pay to the order of _____		\$ _____
_____ DOLLARS		

Here are some suggestions on how to write checks correctly:

(1) The *date* should be written first, and it should be the date on which the check is drawn. If you must make out a check on a Sunday or holiday, date it the previous business day, as checks dated on Sundays or holidays may not be valid in some states. Never write a future date.

(2) The *payee's name* should be written after the printed words "Pay To The Order Of." (The payee is the person or organization to whom the money is to be paid.) Spell the name correctly.

(3) The *amount in words* should be started as far to the left as possible so that no one may insert a word before it and thereby raise the amount. Fill in any unused space with a line.

(4) The *amount in figures* should be written close to the \$ sign, and must agree with the amount in words. If there is a difference between them, the amount in words fixes the amount of the check.

(5) Your *signature* should be written only after all of the other items have been carefully written. Never cross out or change any written part of a check. If you make an error, write "Canceled" across the face of the check and file it with your canceled checks.

A *certified check* is one stamped "Certified" by a bank after it has set aside the required funds from the check drawer's account. The bank thus

certifies or guarantees that the amount of the check will be available when the check is presented for payment.

CHEDDAR, chéd'ēr, village, England, in northern Somersetshire, 22 miles southwest of Bristol at the foot of the Mendip Hills. Renowned since the 17th century for its cheese, the name of which has been copied for similar cheeses in other parts of the world, it lies in a dairying region and is an agricultural center. It is tourist headquarters for visitors to the Cheddar Gorge, a picturesque pass over 400 feet high and two miles long, with limestone walls having famous stalactite caves. Pop. (1931) 2,154.

CHEDORLAOMER, kéd-ör-lā-ō'mēr (also CHEDOR-LAOMER; CHODORLAHOMOR), a Biblical king of Elam. As told in Genesis 14:1-16, Chedorlaomer, with his allies Amraphel, king of Shinar; Arioch, king of Ellasar, and Tidal, "king of the nations," warred upon the cities in the plain of the Jordan, holding them in subjection for 12 years, when they revolted. After ravaging the countryside and winning a battle in the vale of Siddim, he sacked Sodom and Gomorrah and captured Lot, Abraham's nephew. Abraham then pursued and slew Chedorlaomer and his cohorts, setting Lot free.

CHEDUBA, chē-dōō'bā or chéd'ōō-bā, island, Burma, about 20 miles off the coast of Arakan in the Bay of Bengal, in the Kyaukpyu district, separated by Cheduba Strait from Ramree Island, which is between it and the mainland. Its area is 220 square miles. A port and village of the same name is on the northeast coast. Cattle raising and agriculture are followed on Cheduba, and there are oil deposits. The island was held by the Japanese from May 1942 to January 1945. Pop. (1939 est.) 30,000.

CHEERYBLE BROTHERS, the twin brothers, Edward and Charles Cheeryble, in Charles Dickens' novel *Nicholas Nickleby* (q.v.). They are the liberal benefactors not only of Nicholas but also of all with whom they came in contact. Dickens patterned them on William and David Grant, cotton manufacturers of Manchester, England.

CHEESE AND CHEESE MAKING.

Cheese is the concentrated food product obtained by coagulating milk, stirring and heating or cooking the curd, draining off the whey, and collecting or pressing the solid or semisolid curd. The coagulation or curdling is accomplished usually by the enzyme action of rennet or pepsin and less frequently by bacterial souring, or by a combination of both. The name "cheese" alone, unqualified, in the United States connotes the commonest variety, called American cheese, and in England, Cheddar cheese. Most cheese is made from the milk of cows, and smaller quantities from that of goats and sheep. It has also been made in a primitive way from the milk of camels, asses, mares, buffaloes, reindeer, and other animals. The taste or flavor of cheese depends not only upon the kind of milk but also upon the process used.

Historical.—The exact origin of cheese making is unknown. According to an ancient legend, cheese was first discovered accidentally when an Arabian merchant, setting out on a long day's

journey across the desert, put his supply of milk into a pouch made of a sheep's stomach. The heat of the journey and the rennet in the lining of the pouch caused the milk to separate into liquid whey and solid curd. Though not understanding the transformation, he found at nightfall that the whey satisfied his thirst and the cheese satisfied his hunger and had a delightful flavor. Thus the manufacture of one of our most useful foods was begun.

Cheese is recorded as having been made and eaten in Biblical times. It is known to have been used as a food 2,000 years before Christ. It is believed that Asiatic travelers brought the art of cheese making to Europe. Cheese making flourished in many parts of the Roman Empire at its height, and the art was brought to England by the Romans. During the Middle Ages, or from the decline of the Roman Empire until the discovery of America, as well as later, the art of cheese making was carried on and improved by the monks in the monasteries of Europe. The origin of Gorgonzola cheese in the Po Valley in Italy dates back to 879 A.D., and Italy was the most advanced cheese-making center of Europe as early as the 10th century. Roquefort cheese was first mentioned in the ancient records of the monastery at Conques, France, in 1070. Cheese was included in the ship's supplies when the *Mayflower* made its famous voyage to America in 1620.

Prior to the middle of the 19th century, cheese making was strictly a local farm industry, carried on mostly by housewives in farm homes. The first cheese factory in the United States was started in 1851 near Rome, Oneida County, N. Y., by Jesse Williams, and the first cheese factory in England was started in 1870 at Derby. Herkimer County, adjoining Oneida County, was a center of the cheese industry from 1851 to about 1900. For 30 years, beginning in 1861, the market at Little Falls, N. Y. was the largest cheese market in the world. Beside farm-made cheese, the product of about 200 factories was sold there. With the increase in population and demand for market milk, the industry gradually moved westward, centering in the rich farm lands of Wisconsin. Cheese making in the United States and in the other leading cheese-producing countries is now largely a factory industry, only small amounts being made on farms for home use.

Varieties.—A survey of the English, Italian, German, and French literature on cheese making, by the writer, has revealed names and descriptions of 390 kinds of cheese. The list is obviously incomplete, and it is safe to say that there are more than 400 names given to cheeses. Most of these are of only local significance, named usually after the town or locality where they originated or are produced, and are modifications or variants of more widely known varieties. Actually there are about 20 distinct varieties or groups, of which the following are the best-known names: Brick and Muenster; Brie; Caciocavallo, including Provolone; Camembert; Cheddar; Cottage; Cream; Edam; Emmentaler and Swiss; Gouda; Hand; Limburger; Neufchâtel; Parmesan; Process; Romano; Roquefort and Gorgonzola (blue cheeses); Sapsago; Trappist; and whey-albumin cheeses, including Primost and Ricotta.

Classification.—The varieties of natural (non-processed) cheese can be classified conveniently on the basis of body characteristics and type of ripening. Examples are given in the following

classification: (1) Very hard, ripened by bacteria: grating cheeses—Parmesan, Romano, Asiago old, Sapsago, Sbrinza; (2) Hard, ripened by bacteria: without gas holes or eyes—Cheddar, Edam, Gouda, Caciocavallo, Provolone; with eyes—Emmentaler, Swiss, Gruyère; (3) Semi-soft: ripened by bacteria and surface microorganisms—Limburger, Port du Salut, Trappist; ripened principally by bacteria—Brick, Muenster, Gold-N-Rich, Chantelle; ripened by blue mold in the interior—Roquefort, Gorgonzola, Blue, French Bleu, Stilton, Wensleydale; (4) Soft: ripened by bacteria and surface microorganisms—Bel Paese, Brie, Camembert, Cook, Hand, Liederkranz, French Neufchâtel; unripened—Cottage, Pot, Baker's, Cream, American Neufchâtel, Primost, moist Ricotta.

Manufacture.—The manufacturing procedure used generally, with some of the specific modifications for individual varieties, is described as follows: The milk of cows, produced in the evening and morning, may be strained and is poured promptly into milk cans and cooled by running it over a cooler or by placing the cans in cold, running water. It is delivered early in the morning, while still sweet, to the cheese factory. Here it is graded and weighed, inferior lots are rejected, samples are taken for butterfat tests and frequently for quality tests, and it is pumped to a receiving tank.

The milk usually is pasteurized. For Swiss cheese it always is clarified, that is, run through a high-speed, centrifugal clarifier, which removes dust and other particles and greatly improves the formation of gas holes, known as eyes, that form in the cheese as it ripens. Clarification of the milk also reduces "pin-hole" gassy formation in Cheddar and other types of cheese, improving the texture and body or mellowness.

The milk is conveyed from the pasteurizer or clarifier to the cheese vat or kettle. Most vats are rectangular. Cheddar vats may hold as much as 15,000 or as little as 500 pounds of milk. Swiss cheese is made in round, copper kettles holding 2,000 to 3,000 pounds. The vat or kettle is made with a steam jacket for heating the milk. Milk for some kinds of cheese may be standardized, that is, a small proportion of the fat is removed as cream, by means of a mechanical separator, to adjust the composition uniformly. For Swiss cheese about 10 per cent of the fat is removed. In some places removal of fat from milk used in making Cheddar cheese is illegal. The cream removed is either sold as market cream or churned into butter. Some cheese-makers test the rennet-coagulation property of a sample of milk from each vat by means of a rennet test—adding a definite proportion of rennet extract and noting the time required for the rennet to coagulate or curdle the milk sample by its action on the casein. If the milk curdles too slowly, calcium chloride may be added, in a proportion of not more than 0.02 per cent, to aid curdling. To increase the yellow color, a harmless, vegetable coloring extract known as annatto may be added to the cheese milk.

The temperature of the milk is adjusted to a definite point in the range of 86° to 91°F. A bacterial culture, known as a starter, is added. The starter for most kinds of cheese is a mixed culture containing several types of harmless bacteria, which convert the milk sugar or lactose into lactic acid and also aid in the ripening. The production of acid by the proper bacteria helps

CHEESE AND CHEESE-MAKING

Top to bottom: (1) The young man pours the initial culture from the can labeled "Starter" into a vat of milk. (2) The cutting of the thickened curd. (3) The curd is allowed to drain sufficiently and to mat. According to variety, cheeses may be put under various kinds of pressure during these processes. (4) The cheese is packaged on an assembly line for distribution.

CHEESE AND CHEESE-MAKING

Top: Cheeses are soaked in brine tanks in order to form a natural rind before they are stored for curing. Note the round Edam cheeses on shelves in foreground. Left: Tightening the cheese form, a step in the making of Switzerland Cheese. Right: While Switzerland Cheese is being cured the daily washing in the curing cellar is an all-important function. Observe the thoroughness with which each cheese is scrubbed with a brush.

to drain the whey from the curd, helps to "knit" the curd compactly, retards the growth of gas-forming and off-flavor-producing bacteria, and improves the flavor. The use of a starter is very necessary. For Swiss cheese two or sometimes three separate starter cultures are added. The milk may be allowed to ripen and then it is "set" with a small quantity of rennet—usually three ounces of liquid rennet extract per 1,000 pounds of milk—to curdle it.

Usually about 30 minutes after setting, the curd is cut into small pieces. It gradually is stirred and warmed and, after it is sufficiently firm, the whey is drained off or the curd is dipped out. The volume of whey usually comprises 86 to 90 per cent of the volume of the milk. It contains 0.3 to 0.35 per cent of fat in the case of that from Cheddar cheese, or as much as 0.75 per cent in that from Swiss cheese. The whey is separated and the resulting whey cream is used in making butter. The fat-free whey contains nearly one half of the percentage of solids—principally lactose and milk salts or minerals—of the original milk. It usually is fed to livestock, but recently it is being utilized more efficiently as a source of lactose and as concentrated or dried whey solids for many types of human food.

After sufficient draining, the curd may be salted. Cheddar cheese curd is first allowed to mat and then is run through a curd mill and cut into small pieces, after which salt is mixed with it. The curd is placed in hoops or forms, which usually are lined with cloth, and usually is put under pressure overnight. Some types, such as Cottage and Cream cheese, are not pressed but merely allowed to drain in cloths, and hence contain a relatively large percentage of moisture. Some are allowed to settle in perforated forms and are inverted periodically but not pressed, as in the cases of Blue and Brick cheeses. Some hard cheeses, such as Swiss, Parmesan, Romano, and Provolone, are not salted during the draining and firming stage but are immersed later in salt brine. Some softer kinds, such as Blue and Brick cheeses, are salted by rubbing dry salt on the surface during the first week of curing.

The cheese is ripened or cured on shelves and kept clean, in special curing rooms at a temperature usually between 45° and 60°F., or as high as 72°F. in the case of Swiss, and with the relative humidity regulated. After the usual curing, the cheese may be stored and cured more slowly at a lower temperature, as low as 35°F. At least three months' curing is required generally and some types, such as the very hard Italian cheeses, require more than a year.

No two of the principal varieties are made alike. The details of setting, cutting the curd, stirring, heating, draining, pressing, salting, and curing, as well as the adjustment of the composition of the milk and the use of bacterial starters, vary for the different types. Variations in these details determine the kind of cheese and are regulated strictly by the manufacturer in accordance with the art found most favorable for each kind of cheese. Thus, by mechanical manipulation and the use of specific ripening agents, milk is transformed into a much less perishable and more concentrated food product, which may vary in type according to the method of manufacture and the specific biological agents used.

Five thousand pounds of milk per day, or about 500 pounds of cheese, is considered a

minimum quantity for profitable production for sale.

Production.—The principal types of cheese manufactured in the United States, with figures in millions of pounds produced in 1947, are as follows: American type, including Cheddar, 931.9; Creamed Cottage, 230.6; Swiss, 71.6; Cream Cheese, 57.6; Italian varieties, principally Parmesan and Romano, 38.1; Brick and Muenster, 26.5; Blue or blue-veined, 10.6; Limburger, 7.8; full- and part-skim American type, 7.1; Neufchâtel, 4.4; and other minor types, 24.2; total of all cheeses (including Cottage and skim-milk American type), 1,410.4 million pounds.

The principal cheese-producing states in the United States, with figures in millions of pounds produced in 1947, are as follows: Wisconsin, 535.9; Illinois, 86.9; New York, 71.0; Minnesota, 58.9; Missouri, 58.7; Tennessee, 42.4; Indiana, 40.2; Ohio, 34.4; Oregon, 29.2; and Michigan, 28.1. These figures do not include skim-milk Cheddar cheese or Cottage cheese. Exclusive of those two kinds, about 45.5 per cent of all the cheese was produced in Wisconsin.

The production of cheese in the United States more than doubled since 1930. The production of varieties other than skim-milk Cheddar cheese and Cottage cheese in 1930 was approximately 500 million pounds, and the production in 1947 was approximately 1,178 million pounds. The consumption of cheese in the United States increased from 4.6 pounds per person in 1930 and 5.5 pounds per person during the 5-year period 1935-1939 to 7 pounds per person in 1947.

The above-mentioned increases in production and per capita consumption are directly attributed principally to the improvement in quality and in marketing practices as a result of modern, scientific research. By application of newer, more scientific principles of bacteriology, chemistry, physics, and economics, the cheese manufacturers, supplemented by research laboratories of the United States Department of Agriculture and of several state agricultural experiment stations, gradually have replaced the old rule-of-thumb practices with scientific methods. The art of cheese making, by which the different varieties were developed originally, is gradually being replaced by scientific procedures, and thereby the quality of the various cheeses is gradually being improved.

Composition.—The components of cheese include: proteins, of which approximately 95 per cent is casein and the rest mostly albumin; milk fat; water, retained in the form of whey; lactose or milk sugar, in solution in the whey; neutral

Variety	Moisture	Fat	Protein	Salt	Yield per cwt. of milk
	Per cent	Per cent	Per cent	Per cent	Lb.
American (Cheddar)	37	32.3	25.5	1.7	9.8-10.1
Swiss	39	28.0	28.0	1.3	7.5-8.5
Cream	51	37.0	9.0	1.2	
Italian: Parmesan and Romano	27-32	24-28	32-34	5.5	6.0-7.5
Brick	42	30.0	22.5	1.8	9.5
Muenster	43	29.0	23.5	1.8	9.8
Blue mold	41	30.5	22.0	4.5	9.5-10.0
Brie	45	29.0	21.5	1.8	12.0-14.0
Camembert	52.5	25.0	18.0	1.7	13.0-15.0
Limburger	44-47	28.0	22.0	2.0	11.0
Neufchâtel	60	23.0	13.0	1.5	15.0
Cottage: Curd	75-78	0.5	18.5	1.2	12.0-15.0
Creamed	74-77	4.5	16.0	1.0	15.0-17.0

salts and salt acids, including principally calcium lactate, lactic acid formed from the fermentation of lactose, calcium phosphate existing chiefly as the dicalcium salt, and calcium and sodium citrates; common salt or sodium chloride, added to supplement the flavor; vitamins and accessory food substances; frequently added annatto cheese color; and traces of gases, principally carbon dioxide.

Typical composition and yield data for the principal varieties of cheese made in the United States are given in the preceding table:

Nutritive Quality.—Cheese is one of our most concentrated, nutritive, and palatable foods. With the exception of butter, which contains more fat and less moisture, it is the most nutritious ready-to-eat dairy product. For high-quality, complete protein, fat, the essential minerals calcium and phosphorus, a variety of vitamins, and other nutrients from milk, it is very doubtful if there is any basic food which excels cheese.

It is an excellent dietary source of milk minerals. Cheddar cheese contains approximately 0.75 per cent of calcium and 0.5 per cent of phosphorus. Swiss cheese contains approximately 1 per cent of calcium and 0.6 per cent of phosphorus. Cheese is an excellent source of fat-soluble vitamin A, a good source of riboflavin, and a fair source of thiamin and of niacin. It is also a very useful source of a material which either supplies the recently isolated vitamin B₁₂ or functions like this vitamin in being a potent growth stimulant in the normal mammal and in determining the capacity of an animal to utilize protein.

Ripening.—The ripening of cheese involves changes in the protein, principally casein, from an insoluble to a soluble and more readily assimilable form, yielding "break-down" products which are classified as proteoses (caseoses and albumoses), peptones, amino acids, and ammonia. It involves also hydrolysis or splitting of the lactic acid and lactates to yield volatile fatty acids. In some cheeses milk fat is hydrolyzed or broken down and yields fatty acids. These acids, which produce sharp flavors, are break-down products not only of carbohydrates and fats but also of proteins. The ripening changes occur slowly, their rates depending largely upon temperature and moisture content. They take place after the lactose present in the cheese has been converted to lactic acid and calcium lactate by microorganisms and enzymes. The lactic-acid fermentation and the subsequent ripening changes occurring in the protein, fat, and carbohydrate by the action of microorganisms and enzymes are the causes of the sharp, piquant flavors which occur in ripened cheeses.

The enzymes which take part in ripening and the production of flavor include: lactases, proteases, and lipases, which are produced by microorganisms; galactase, which is present in the milk; and rennin, which is the principal enzyme in rennet extract. The milk-coagulating and protein-digesting activity of rennin is similar to that of pepsin, which is normally a stomach enzyme and which may be present also in rennet extract. The cheese-ripening activities of these enzymes are dependent upon the presence of the acid produced in the preliminary, bacterial, lactic-acid fermentation.

The ripening changes in cheese may be looked upon as a predigestive process, whereby the milk casein and other colloidal constituents are ren-

dered more easily digestible and assimilable in the digestive tract when cheese is eaten.

Pasteurization.—Pasteurization of milk for use in cheese is probably the most important recent advance in cheese making. In this process the milk is heated to at least 160°F. and held at that temperature for at least 15 seconds, or to at least 143°F. for at least 30 minutes, and then cooled. The heat kills any disease-producing microorganisms which may be present, thus ensuring the consumer a safe product. It also kills other types of harmful or undesirable microorganisms, thus making it possible to control better the desirable bacterial fermentation by the addition of scientifically prepared bacterial starters. Research in the United States Department of Agriculture has proved that pasteurization of the milk, in the cases of numerous kinds of cheese, greatly improves the quality and uniformity. At least one half of the cheese made in the United States is made from pasteurized milk, and the use of the process is increasing rapidly. The United States Department of Agriculture has developed a so-called phosphatase test, by which the use of unpasteurized milk can be detected in cheese (Sanders-Sager Test). Regulations of the Food and Drug Administration in the United States require that the milk for Cottage and other unripened varieties be pasteurized and that the milk for most of the ripened varieties be pasteurized or the cheese ripened for a definite period—usually 60 days—before retail sale. Some kinds, such as Swiss, have not yet been made successfully from pasteurized milk, and in such cases a definite ripening period is legally required in order to meet government regulations.

Pasteurized Processed Cheese.—The manufacture of processed cheese has become an important part of the cheese industry. Processed cheese is made by grinding, mixing, and pasteurizing ripened, natural Cheddar cheese, or a blended mixture of various cheeses, usually with a chemical emulsifier, salt, and annatto color, and packaging the hot product in sanitary, attractive packages or glass containers. Nonfat milk solids, concentrated or powdered whey, pimientos, olives, and other non-cheese foods sometimes are blended and pasteurized with cheese mixtures, including Cream cheese, and the products are sold in sanitary, attractive packages or glass jars as pasteurized processed cheese foods. The softer blends are marketed as cheese spreads. At least one third of the natural cheese made in the United States is reworked thus and marketed as processed cheese.

States Department of Agriculture.

CHEESE FLY, a small, black, dipterous insect bred in cheese, belonging to the Muscidae, the same family to which the housefly and blowfly belong. It has a very extensible ovipositor, which it can sink to a great depth in the cracks of cheese and lay eggs there.

The maggot, well known as the cheese hopper, or cheese skipper, is furnished with two horny claw-shaped mandibles, which it uses both for digging into the cheese and for moving itself, since it has no feet.

CHEESMAN, Forman, American ship-builder and naval architect: b. New York, N. Y., Dec. 11, 1763; d. there, Oct. 10, 1821. The son of a New York shipbuilder, he constructed his first ships in his father's yards on New York's East River front between the present Pike and Rutgers streets.

During a partnership with Charles Brownne, builder of Fulton's *Clermont*, his yards were further uptown at Clinton and Cherry streets. Cheesman received the contract from the United States government for construction of the famous 44-gun frigate *President* which was built and launched (1800) in the yards of Christian Bergh. What share of credit each of these noted builders deserves for the design and construction of this model of 18th century naval architecture it is impossible to determine. Later, during his partnership with Brownne, Cheesman built some of the finest ships of the day, including the *Silenus*, the *Triton*, and the *Illinois*.

CHEETAH, ché'tà, a large, spotted, maned cat (*Acinonyx jubatus*), also known as hunting leopard. It occurs throughout Africa except in the humid forested parts, and in Asia in the more or less arid regions from India and Russian Turkestan to Syria and Arabia. The cheetah is comparable to a greyhound in the slender form of its body and the length of its legs. The cat is highly specialized for running and is regarded as the fastest animal on earth. A full grown male measures from four to five feet in combined head and body length; the tail is about two-thirds as long. The weight of the animal varies from 100 to 200 pounds. Females weigh half as much and are from one-third to one-fourth less in bodily dimensions. The ground color of the body is gray, buff, or tawny, marked with closely set solid spots, rarely with blotches or bands. A conspicuous black stripe extends from the eye to the mouth on each side. The mane of the cheetah is a remnant of an extensive matlike growth of long hair that covers the whole upper side of the cubs. A more important distinctive character is the absence on the toes of protecting sheaths for the claws when retracted.

The cheetah is mainly diurnal, lives in open plains or bordering foothills, and makes its den in any kind of cover or rocky shelter. It climbs when young but seldom does so when adult, unless treed by dogs. Instead of stalking or ambushing and leaping on its prey from close quarters, like the majority of cats, the cheetah runs down its quarry by sheer speed of foot. A cheetah can

travel at a speed of 65 or, in a short spurt, 70 miles per hour, but its endurance is low. The maximum speed can be maintained for probably no more than 100 yards, and the distance of a quarter mile is covered at the rate of 45 miles per hour, or in about 20 seconds.

The cheetah is easily tamed but is not known to reproduce in captivity. It is docile and quiet and can be led on a leash. Employment of cheetahs for coursing antelopes and other fleet-footed game dates from the pre-Christian era. In India, the cheetah is usually taken blindfolded in a cart to the scene of the hunt. In the proximity of a herd of antelopes, it is unhooded and unleashed. If the quarry is near, the cheetah captures it after a few bounds. If, however, the antelopes have a good running start, the cat may become winded and abandon the chase.

CHEETHAM, chêt'am, James, Anglo-American journalist: b. in or near Manchester, England, c.1772; d. New York, N. Y., Sept. 19, 1810. He worked as a hatter in Manchester and, after joining the Constitutional Society there, was arrested in July 1793 and imprisoned with others of his society on charges of conspiring against the government, but was released the following April, for lack of evidence. The Manchester riots of 1798 caused him to emigrate to the United States. Settling in New York, he bought a half interest in Thomas Greenleaf's *Argus*; in partnership with David Denniston, a cousin of De Witt Clinton, he published it from May 1, 1801, as *The American Citizen*, a daily devoted to the Republican (modern Democratic) cause. In the split between the Clinton and Burr factions, he espoused the Clinton side and bitterly attacked Burr whom he charged with making a treacherous alliance with the Federalists. His opposition to the Embargo Act (1807), however, cost him the favor of the Clintonians. He wrote a very prejudiced *Life of Thomas Paine* (1809).

CHEEVER, Ezekiel, American educator: b. London, England, Jan. 25, 1615; d. Boston, Mass., Aug. 21, 1708. Having received a good classical education at Christ's Hospital and Emmanuel College, Cambridge, he emigrated to America in 1637, going first to Boston and then, in 1638, to New Haven, where he was appointed master of the public school. In 1650 he moved to Ipswich to become head of the Free School, which he made famous throughout the New England colonies. In 1661 he established a school at Charlestown, and then in 1670 was appointed master of the renowned Boston Latin School, over which he presided for 38 years. He was one of the most notable schoolmasters of colonial America. His *Accidence, a Short Introduction to the Latin Tongue* was a standard text in New England schools for almost 200 years; it had its 20th edition in 1785 and was reprinted as late as 1838. He also wrote a group of three essays entitled *Scripture Prophecies Explained*.

CHEEVER, George Barrell, American clergyman: b. Hallowell, Me., April 17, 1807; d. Englewood, N. J., Oct. 1, 1890. He was graduated at Bowdoin College in 1825 and at the Andover Theological Seminary in 1830. In 1838 he became pastor of the Allen Street Presbyterian Church in New York, and from 1846-1867 was pastor of the Church of the Puritans, New York. He distinguished himself as an

antislavery advocate in the period prior to the American Civil War. During 1845–1846 he was editor of the *New York Evangelist*, and at various times he was connected with the *New York Observer* and *Independent*. He was an able and vigorous writer and speaker, and the author of a large number of works in prose and verse. Among his publications are *Studies in Poetry* (1830); *God's Hand in America* (1841); *Poets of America* (1847); *Windings of the River of the Water of Life* (1849); *The Voice of Nature and Her Foster-Child, the Soul of Man* (1852); *Lectures on the Life, Genius, and Insanity of Cowper* (1856), arguing that Cowper's religious terrors proved him sane instead of insane; and *God Against Slavery and the Freedom and Duty of the Pulpit to Rebuke It* (1857). One of his most effective works was *Deacon Giles' Distillery*.

CHEFOO, ch'fōō', China, treaty port in the province of Shantung, most easterly of the Chinese provinces. The port was opened to foreign trade in 1863. It is served by the railway between Tsingtao and Tsinan. The city is the center of the hairnet industry of China, and it is also important as a fruit and fishing center. Numerous factories make pongee silk and bean oil, and these, together with straw braid, constitute the principal exports. Pop. (1947 est.) 227,000.

CHEHALIS, chē-hā'lis, town, Washington, county seat of Lewis County, situated at an altitude of 204 feet, 35 miles south of Olympia; it is served by the Northern Pacific, Union Pacific, Great Northern, Chicago, Milwaukee and St. Paul, and Cowlitz, Chehalis, and Cascade railroads. Chehalis has lumber and milk-processing plants. It has a commission government. Pop. (1950) 5,639.

CHEHALIS RIVER, Washington, in the southwestern part of the state. It rises in Lewis County, flows north-northwest through Chehalis County, into Gray's Harbor. Its length is 125 miles, and is navigable for light steamers some distance from the mouth.

CHEILOGNATHA, kī-lōg'nā-thā, or **CHIOGNATHA**, also known as *Diplopoda*, one of the two orders of *Myriapoda*, including the millipedes (q.v.) and other forms. See also *MYRIAPODA*.

CHEILON. See *CHILON*.

CHEIROLIN, kī-rō-līn, is a colorless and odorless crystalline compound having the formula $C_6H_5NO_2S_2$, a molecular weight of 179, and a melting point of 47°C. Cheirolin is found as a glycoside in seeds of *Cheirinia cheiri*, the wall-flower, and in some species of *Erysimum*.

CHEIROPTERA, kī-rōp'tē-rā, an order of mammals, the bats, closely related to the insectivores and characterized by the immense extension of the forelimbs so as to form wings and by other adaptations of the skeleton for an aerial life. The order is divided into two groups: *Megachiroptera* and *Microchiroptera*. The former consists wholly of the great fruit-eating bats of the Old World tropics; the latter contains all the remaining families. They are separated principally by dental features. See also *BAT*.

CHEIROTHERIUM. See *LABYRINTHO-DONTA*.

CHEJU, chā'jōō, an island 60 miles south of Korea, known also as *QUELPART ISLAND* and, to the Japanese, as *SAISHU*. It is 700 square miles in area, and is mountainous, the highest point being the volcanic Halla-san (6,398 feet). Fishing and farming are the principal industries, most of the work being done by women. Quantities of seaweed are exported, and also clam shells which, because of their iridescent mother-of-pearl character, are used for inlaying lacquer. American missionaries are active on the island. According to tradition, three divine men came out of caves (still to be seen) and founded the country of Tamna, as Cheju was originally named. The island paid tribute to the mainland as early as 100 A.D., and later was incorporated into Korea. The capital is Cheju, located on the northern coast of the island; in 1946 the entire island had a population of 276,148, of whom 57,573 lived in the capital.

CHEKE, chēk, **SIR JOHN**, English classical scholar: b. Cambridge, June 16, 1514; d. London, Sept. 13, 1557. He was educated at Cambridge University, where he became regius professor of Greek in 1540, a post he occupied until 1551. Meanwhile, he was appointed tutor to the prince of Wales (later Edward VI) in 1544, and was named provost of King's College, Cambridge, in 1548. In 1551 he was knighted, but in 1553, because he served as secretary of state for Lady Jane Grey during her reign of nine days, he was arrested on the orders of Queen Mary. Released the following year, he went abroad, visiting Switzerland and Italy before settling in Strasbourg, where he supported himself by teaching Greek. In 1556 he was seized near Brussels when returning from a visit to his wife and sent to England. There through John de Feckenham he recanted his Protestant beliefs and was received into the Roman Catholic Church by Cardinal Pole. His chief distinction was the impulse given by him to the study of Greek.

CHEKHOV, **CHEKOV**, or **TCHEKHOV**, chā'kōf, **Anton Pavlovich**, Russian playwright and fiction writer: b. Taganrog, Jan. 17, 1860; d. Badenweiler, Germany, July 2, 1904. He took a medical degree at Moscow in 1884 but practiced his profession for only a short period. At the age of 19 he began writing short stories under the pen name of "Chekhonté." The favorable reception accorded his first volume of stories encouraged him to desert medicine for literature, where his scientific training was to prove of inestimable value. His mental trend was from the first inclined to the banal aspects of Russian life. With grim satire he seized on all that was petty, mean, and sordid in human character, and with Maksim Gorki (Maxim Gorky), became one of the most prominent exponents of the Russian school of sordid realists. Chekhov's writings reveal a crowded stage of humble characters—aristocrats are excluded—photographed from life. merchants, students, priests, schoolmasters, saloon-keepers, magistrates, neurotics, lunatics, officials, with all their mean sordidness and narrow-minded simplicity. Where he introduces doctors—which is frequently—he revels in describing physical and mental diseases, of which latter *The Black Monk* is the best example. An atmosphere

of sadness and hopelessness pervades his characters and impresses itself upon the reader. Yet Chekhov is one of the great masters of the modern short story—brilliant, of penetrating psychology, with a remarkable flow of language, and a weird faculty of suddenly turning a humorous situation into a painful tragedy. His fame rests on his stories and such plays as *Ivanov* (1887), *The Sea-gull* (1896); *Uncle Vanya* (1899), and *The Three Sisters* (1901); his dramatic masterpiece was *The Cherry Orchard* (1904, q.v.).

Consult Toumanova, Nina A., *Anton Chekhov, the Voice of Twilight Russia* (New York 1937); Bruford, W. H., *Chekhov and His Russia* (New York 1948); and Magarshack, D., *Chekhov, a Life* (London 1952).

CHEKIANG, jū'ji-āng', province, China, on the East China Sea, lying north of Fukien and south of Kiangsu. The area, including the Chu Shan Archipelago, is approximately 39,750 square miles, and the population, as estimated in 1952, was 19,942,000. Most of the surface is mountainous, drained by numerous rivers. The province is rich in mineral deposits, coal being found in the north and iron ore in the south, while traces of copper occur in several places. Though comparatively small, densely populated Chekiang is among China's most fertile provinces. A high grade of tea is grown on the mountain slopes, and in the lowlands large areas are devoted to rice, cotton, peanuts, wheat, and beans; silk is also an important product, and there are extensive fisheries. Hangchow, the capital, is connected with Peking by the historic Grand Canal; it was one of the first treaty ports to be opened to foreign commerce. Other such ports were Ningpo (now Ninghsien) and Wenchow (now Yungkia), the latter at the mouth of the Wu Kiang. Ninghsien and Hangchow are connected by rail northward with Shanghai, and a railroad extends across Chekiang in a southwesterly direction, affording communication with Kiangsi Province.

Marco Polo visited Chekiang in the 14th century, viewing many beautiful temples which subsequently fell into ruins. During 1861 the province suffered great spoliation at the hands of the Taipings (q.v.); and it was frequently the scene of fighting in the Chinese civil wars of the early part of the 20th century. The Japanese caused considerable damage during their occupation in World War II. Chekiang passed to Communist control in 1949.

CHELAN, Lake, shě-lān', Washington, in Chelan County, bordered on the west shore by the Chelan Range, a branch of the Cascades. Lying in a glacial gorge at an altitude of about 1,000 feet, the lake extends approximately 55 miles and is from 1 to 2 miles wide. Fed chiefly by the Stehekin River at its northwest end, it drains into the Columbia River at the southeast end where the resort town of Chelan (1950 pop. 2,157) is located.

CHELIA, Djebel, jā-bēl' shā-lyá' (Arab. JEBEL SHELIA, jā'bāl shā-lī'yá'), highest peak of Algeria, North Africa, in the Aurès Mountains of the Atlas Range, about 50 miles northeast of Biskra. The Djebel Chélia rises to 7,641 feet.

CHELIF, shā-lēf', or **SHELIF**, shē-lēf', river, Algeria. Rising in the Atlas, the Chélif flows for about 430 miles first north and then west—parallel to the coast through a fertile valley—to the Mediterranean northeast of Oran.

The country's principal stream, it is used for irrigation and, since 1942, for hydroelectric power.

CHELLEAN EPOCH, chēl'ē-ān, in archaeology, pertaining to the culture of the early Paleolithic, the name deriving from Chelles (Seine-et-Marne), France, where chipped stone axes, borers, and scrapers were unearthed. In this epoch man first learned to shape stones for use as instruments. The Chellean Epoch corresponds to the last interglacial period. See also **STONE AGE**.

CHELLY CANYON. See **CANYON DE CHELLY**.

CHELM, kēlm (Russ. Kholm, kôlm), city, Poland, in Lublin Province, about 40 miles east of Lublin, near the USSR border. It is a rail junction, also a processing and trading center for productive farming region. Awarded to Austria in 1795 and to Russia in 1815, it was returned to Poland in 1921. Chelm was the site of a German World War I victory (August 1915) over the Russians. In World War II, a new Polish Republic was proclaimed here on July 22, 1944. Pop. (1946) 23,329.

CHELMNO, kēlm'nô (Ger. CULM or KULM, koolm), city, Poland, in Bydgoszcz Province, on the Vistula, about 24 miles northeast of Bydgoszcz (Bromberg). Its industries include iron and engineering works, furniture factories, saw and flour mills, and breweries. The town developed around a fort built by the Teutonic Knights in 1231. It became a bishopric in 1245 (moved to Pelplin in 1821). Later Chelmno flourished as a member of the Hanseatic League, and was a part of Poland from the 15th to the 18th centuries. Prussia held it until it was transferred after World War I to Poland. Pop. (1946) 11,634.

CHELMSFORD, chēms'fērd, English baronial title held by members of the Thesiger family. The 1st Baron Chelmsford was **FREDERICK THESIGER** (1794–1878). Grandson of a Saxon immigrant, he served as a midshipman in the navy, was called to the bar in 1818, and at the Chelmsford assizes won a famous case in 1832; years later he chose the town name for title. Solicitor general in 1844 and attorney general in 1845, he was appointed lord chancellor in 1858.

His eldest son, **FREDERIC AUGUSTUS THESIGER** (1827–1905), succeeded as 2d baron. Entering the army he served in the Crimean War, was adjutant general in the Abyssinian campaign of 1868, and adjutant general of the forces in India (1869–1874). Promoted major general in 1877, he had chief command of the British troops in the Zulu War of 1879, defeating Cetewayo. His eldest son, **FREDERICK JOHN NAPIER THESIGER**, 1st Viscount Chelmsford (1868–1933), was viceroy of India (1916–1921) and held other high offices.

CHELMSFORD, England, municipal borough and county town of Essex, at the confluence of the Chelmer and the Cann, about 30 miles northeast of London. Manufactures include agricultural implements and electrical machinery. Its church of St. Mary dates from the 14th or 15th century; and the grammar school was founded by Edward VI in the 16th century. Pop. (1951) 37,888.

CHELMSFORD, chēms'fērd, town, Massachusetts, in Middlesex County; altitude 149 feet; about 4 miles southwest of Lowell; on the New York, New Haven and Hartford Railroad. Chelmsford is in an agricultural region and has textile, beverage, wool processing, and wooden box manufactures. The Billerica State Forest is nearby. Historic buildings include the Fiske House dating from 1790 and the Unitarian Church erected in 1840. The town was settled in 1633 and incorporated in 1655. Government is by selectmen. Pop. (1950) 9,407.

CHELSEA, chēl'sī, metropolitan and parliamentary borough, England, in Middlesex County; a southwestern suburb of London (area 1.03 square miles); on the north side of the Thames River, and chiefly distinguished for the royal military hospital that is located there. Situated on the left bank of the Thames, it is, like the famous left bank of Paris, renowned for its historic association with literature and art. Many artists and writers have lived in Chelsea. Among them, Dante Gabriel Rossetti, Leigh Hunt, Sir Robert Walpole, J. M. W. Turner, Whistler, Count D'Orsay, and Thomas Carlyle. In the 17th and 18th centuries Chelsea was the home of Francis Atterbury, Jonathan Swift, Steele, and Smollett. The house in Cheyne Row where Carlyle, known as the "Sage of Chelsea," lived for nearly 50 years is preserved as a monument to his memory, and many Carlyle relics are displayed therein. In the Cheyne Walk is a tablet indicating that Turner died there in 1851. Whistler also lived and died in Cheyne Walk. The borough is also famous for its Royal Hospital and Chelsea Old Church. See LONDON—*Ecclesiastical London* (Pre-Fire Churches).

The Duke of York's School for the children of soldiers, formerly situated near the hospital, has been removed to Dover. There are great military barracks at Chelsea, but these are not within the boundaries of the borough. Chelsea has a public library replete with a rare collection of books on local history. The borough returns one member to Parliament.

The Hospital.—The Royal Hospital, Chelsea, for old and invalid soldiers was begun in the reign of King Charles II. According to tradition he acted at the instigation of Nell Gwyn who never forgot her humble origins and loved to help the aged and the poor. The expense was undertaken at a time when the exchequer of Charles was at a low ebb, and he could ill afford it. The work was carried on during the reign of King James II and finished in that of William and Mary by Sir Christopher Wren, in 1692. It is also a military museum wherein are displayed the colors captured in historic British battles, including Waterloo. There are also other military exhibits.

Chelsea Hospital grounds cover about 66 acres. A building was originally commenced here by James I as a theological college, but it was never finished. Ranelagh (q.v.), often referred to in English literature, a fashionable resort and place of entertainment in the 18th century, was located in the grounds of Chelsea Hospital. Early in the 19th century its popularity waned, and it was closed. Cremorne Gardens, popular and fashionable in the mid-19th century, also were situated here.

The commissioners of the hospital administer the Army Pension List. All pensions are granted

by these commissioners, and most of the recipients are known as out-patients. Their number runs into many thousands. From these the in-patients are selected. The number of in-patients runs into the hundreds; they are soldiers maimed or disabled in military service, or who have served for 21 years. On May 29th, which is known as Oak Apple Day, the old Chelsea pensioners don their scarlet frock-coats to celebrate the occasion. Oak Apple Day commemorates the time when King Charles lay hidden in the branches of an oak tree while Cromwell's "Ironsides" were searching for him. Pop. (1951) 50,912.

CHELSEA, city, Massachusetts, Suffolk County; altitude 10 feet; on the Boston Harbor between the Mystic River and Chelsea Creek estuaries; 3 miles north of Boston and sharing that city's port facilities; served by the Boston and Maine and the New York Central railroads. Chelsea is chiefly an industrial city, but is also an important shopping center for surrounding suburban communities. Its manufactures include shoes, lithographic materials, elastic goods, foundry products, chemicals, and food and wood products. Chelsea's main business section, most of its public buildings, schools and churches, and a large residential area are of new construction since the great fire of April 12, 1908. At that time 492 acres in the heart of the city were ravaged, and 17,000 people were left homeless. The city was rebuilt within two years, and it has since had its largest commercial development.

Chelsea has a city hall whose design is based on that of Independence Hall in Philadelphia; a Carnegie public library; excellent public parks; and an 8,500-seat War Memorial Stadium in Carter Field. The Massachusetts Soldiers' Home is here, and there is a United States Naval Hospital. Founded as a trading post by Samuel Maverick in 1624, Chelsea was known by its Indian name of Winnisimmet and was a part of the town of Boston until it was set off as a separate township in 1739. It received its city charter in 1857, and has a mayor and aldermen. Pop. (1950) 38,912.

CHELSEA PORCELAINS. The first successful English porcelains were made in Chelsea. The factory stood in what is now a borough of London, along the Thames and a mile from Buckingham Palace, but then classed as a "large and populous village one mile west of St. James's Park." Practically from the start, useful wares, figures and other ornamental pieces were made, and from 1745 to 1784 Chelsea dominated English porcelain manufacture in quality and quantity. This was due to the skill and business acumen of three men, Charles Gouyn, Nicolas Sprimont, and William Duesbury. The first was a jeweler, the second a silversmith, and the third a porcelain decorator.

Chelsea porcelains are divided into five periods: Triangle, 1745–1750; Raised Anchor, 1750–1753; Red Anchor, 1753–1758; Gold Anchor, 1758–1770; and Chelsea-Derby, 1770–1784. In 1784 the Chelsea factory was dismantled and its models shipped to the Derby porcelain factory by Duesbury who owned both.

As far as is known the first pieces of Chelsea were small cream jugs, marked on the base beneath the glaze with an incised triangle. There are known examples where this mark is augmented by the word *Chelsea* and the date 1745

Known as "bee and goat" jugs because of their design, the body is supported on the backs of two reclining goats and decorated on the front with sprays of flowers in relief on which a nicely modeled bee has alighted. Earlier silver originals, from which this design was copied, bear the London hallmarks for 1724 and 1737-1738.

Charles Gouyn, who started porcelain making at Chelsea, was a Huguenot jeweler who settled in London sometime before 1745. The close similarity between the paste and glaze of very early Chelsea pieces and those of the French porcelain factories makes it tenable that he employed one or more fellow Huguenot refugees with intimate knowledge of porcelain making as practiced at St. Cloud, Chantilly, or Mennecey-Villeroy. Also, distinctly English modeling of some of the Chelsea figures attributed to the Triangle period indicates that some of his employees were probably recruited from Staffordshire.

Chelsea pieces of this period have a soft glass-like paste and a soft white shiny glaze that is not likely to craze. Those of the useful wares, especially, are very translucent and have a pale misty ivory tone with tiny pinholes in the glaze brighter than the surrounding surface. These useful wares have a raised decoration inspired by the Chinese or Japanese and derived via Meissen. Shapes were consistently borrowed from contemporary silver and are now known as "silver shapes." Outstanding and rare examples of these wares, in addition to the goat and bee pitchers, are shell-shaped salt dishes, tall coffee tops with applied floral sprays, and teapots in the form of a grotesquely modeled Chinese.

Figures were in the minority during the Triangle period. Most of them are in the white glaze but a few have small sprays or sprigs of flowers that may have been added by outside decorators. The modeling is French but the posing, English.

There were notable changes in 1750. First, Nicolas Sprimont replaced Charles Gouyn. Sprimont was born in Liège, France and by 1742 was working in London as a silversmith. He recognized the need of backing by a person of prominence for his porcelain venture and so secured the interest of William Augustus, duke of Cumberland and son of George II, who bespoke (that is, ordered) a set of Chelsea "for his own table." This quasi patronage by royalty was accomplished through Sir Everard Fawkener (1684-1758), a man of wealth with important connections which he used for the benefit of the venture, such as arranging with Sir Charles Hanbury Williams, then in Dresden for the loan of some Meissen porcelains for use as models "to furnish the undertakers with good designs."

Fawkener continued to be closely associated with Chelsea until about the time of his death in 1758 when he left his family in "reduced circumstances." His connection with the business covered the Raised Anchor and Red Anchor periods when Meissen influence was at its height. His high regard for the Saxony porcelain works probably accounts for this since after Sprimont became sole proprietor the influence of Sèvres and other French factories were steadily more marked.

By 1754 the Chelsea factory was on such an extensive footing that its first annual auction of useful and ornamental porcelains was announced in the *Public Advertiser* for March 29. It lasted for 14 days and was so successful that another, devoted entirely to patch boxes and kindred

small pieces, known as toys, was held. The annual sale of 1755 lasted 16 days. Statistical analysis of the lots listed shows that there were items of 9,600 useful wares and 800 figures and other ornaments. Since the factory was also maintaining a salesroom in Pall Mall, it is likely that about half as much more Chelsea was sold there. Adding in the pieces made on order, an estimate of an annual production of approximately 15,000 pieces of useful wares and 1,200 figures and other ornaments seems warranted.

Pieces in this sale must have borne the Red Anchor mark since this period lasted from 1753 to 1758 and during it the best Chelsea figures were produced. Just when the Red Anchor completely replaced the Raised Anchor has never been established. For a while both were used interchangeably and there was no break in form of pieces or style of decorating.

The Red Anchor paste is of a colder white than that of the Raised Anchor period and has the so-called moons of greater translucence in the body. They were the result of adding coarsely ground frit to the mixture to make the pieces stand up better during firing. The Red Anchor mark with rope ring at the upper end is small, always in overglaze enamel done in red or sometimes brown. A few are known where the anchor is in blue without the ring.

The year 1758 marks the beginning of the Gold Anchor period which continued to 1770. During it Sprimont remained at the head of the factory until 1769 when he sold the business to James Cox who within the year sold it to William Duesbury. The character of Chelsea porcelains changed materially in this period. A new paste containing as much as 40 per cent bone ash was adopted. A number of new techniques were perfected, including colored ground colors and the rococo influence was high. Due to wars on the Continent, the Meissen influence declined and the style of the Sèvres factory became the one which set the fashion.

Under this French influence, Chelsea increased its use of ground colors, including mazarin blue, turquoise, yellow, green and a particular shade of red, often referred to as claret. This was one of the factory's triumphs that resulted from an attempt to copy the rose Pompadour of Sèvres. Elaborate gilding was also added to the decorations. The mark for this period is a small anchor with rope ring at upper end done in over-glaze gilt. The paste is soft and uniform without the earlier moons. The glaze has a high brilliance but is thick and glassy and sometimes forms small pools with a greenish tinge. It is either off-white or very white and some pieces show parallel crazing. Pieces are very translucent and show a shade of either pale pinkish ivory or an even whiteness.

In 1770 William Duesbury, owner of the Derby factory, became the proprietor of Chelsea. With this came the start of the Chelsea-Derby period which lasted until 1784 when all production was transferred to Derby. Although pieces of this period are excellent examples of 18th century English porcelain, they are not held in as high regard as earlier Chelsea. The Chelsea-Derby mark is a combination of the anchor and a capital script D, sometimes side by side and sometimes combined as a cipher. See also DERBY PORCELAINS.

CHELSEA VILLAGE, now part of New

York. The name is preserved in Chelsea Square between Ninth and Tenth avenues and Twentieth and Twenty-first streets. Clement C. Moore, author of *'Twas the Night Before Christmas*, owned a farm here in the early 19th century.

CHELTENHAM, chēlt'nām, municipal borough, England, a popular watering-place in the county of Gloucester, seven miles northeast of the city of Gloucester, on the river Chelt, a short tributary of the Severn, 85 miles from London. It is a city of gardens, protected by hills and surrounded by beautiful scenery. Cheltenham spas first occasioned the rapid growth of the town, but the baths and springs are less frequented than formerly. The springs were discovered in 1716, but became famous in 1788 through a visit paid to them by George III. There is a college for boys (founded in 1840), the ladies' college (founded in 1854), and a Church of England teachers' college. Industries include the manufacture of bricks, rubber goods, aircraft, and anaesthetics. Cheltenham returns one member to Parliament. Pop. (1947 est.) 64,420.

CHELTENHAM, township, Pennsylvania, in Montgomery County, altitude 65 to 415 feet, on the Reading Railroad, 11 miles north of Philadelphia, and on state highways. It has furniture and hosiery factories, and is the seat of two private schools. First settled in 1690, it was incorporated as a township in 1900. It has commission government and a city manager. Pop. (1930) 15,731; (1940) 19,082; (1950) 22,854.

CHELYABINSK, chī-lyá'byĩnsk, or **CHELIABINSK**, city, USSR, on the left bank of the Mias River, 125 miles south of Sverdlovsk, with which it is connected by rail, as also with all the major industrial regions of the USSR. An agricultural and coal region, it manufactures farm machinery and tanks. Pop. (1939) 273,127.

CHELYUSKIN, chī-lyōōs'kĩn, or **CHELIUSKIN**, Cape (also NORTHEAST CAPE or CAPE SEVERO), USSR, the extreme northern point of Asia, on Taimyr Peninsula. It was named after a Russian officer who led an expedition thus far in 1742, and there succumbed to the fatigues of the journey; it was not revisited until 1778, when Nils Adolf Nordenskjöld, in the *Vega*, spent August 19th and 20th there.

CHEMICAL AFFINITY, the force or tendency which causes two or more dissimilar substances to combine in definite proportions to form a new substance whose properties are distinct from those of any of the constituents. The word *affinity* was originally employed in this sense because it was believed that a kind of relationship existed between substances that are capable of combining with one another. In the time of Aristotle the constituent particles of bodies were conceived to be endowed with qualities somewhat akin to love and hate. After the advent of Galileo, these notions were exchanged for equally erroneous but more mechanical ones, and the ultimate particles were represented, in thought, as provided with hooks and other similar devices, by means of which their combinations were conceived to be effected. Later, when the law of universal gravitation was propounded by Newton, the force impelling the atoms toward

one another, and holding them in their combinations, was naturally enough pictured as a special form, or manifestation, of gravitative action.

Modern science accounts for the tendency of one element to combine with another on the basis of atomic structure. The number and arrangement of the electrons surrounding the positive nucleus determine the chemical character of an element. The electrons in the outermost orbit or shell are the *valence electrons* which are involved in chemical reactions. For example, the sodium atom has a single electron in its outermost shell and this electron is very easily removed. The chlorine atom has 7 electrons in its valence shell. An outside shell of 8 electrons is remarkably stable. Hence the chlorine takes an electron from the sodium atom to complete a shell of 8 electrons; the sodium atom in losing its single valence electron exposes a stable shell of 8 electrons. The sodium atom has a positive charge and the chlorine atom a negative charge, and the crystal of sodium chloride is made up of alternate atoms of opposite charge. When a chlorine atom combines with a hydrogen atom, there is a sharing of electrons, one from the hydrogen and one from the sodium, and a bonding pair is formed.

The further the valence electrons are from the nucleus, the more easily are they lost. In the old terminology it would have been said that chlorine has a greater affinity for potassium than it has for lithium. The modern concept is that the potassium atom loses its valence electron more readily because it is much further from the nucleus than the valence electron of lithium. In the same way, fluorine attracts an electron from sodium much more readily than does iodine because its valence shell is nearer to its nucleus and has greater drawing power.

The activity of elements can be measured by electromotive forces, ionic concentrations being made equal. Measured against a hydrogen-hydrogen ion half cell, a zinc-zinc ion half cell has an electromotive force of -0.76 volt, while a cadmium-cadmium ion half cell would give a value of -0.40 volt. In the old system it would have been said that a given element had a greater affinity for zinc than for cadmium.

Matters of protective films, concentrations, temperatures, pressures, and catalysts must also be taken into consideration in connection with chemical reactions, and comparisons of activity can be made only when conditions are alike and interfering factors can be eliminated. See also ATOMIC THEORY; CHEMISTRY; ELECTRON THEORY; ELEMENT; PERIODIC LAW.

W. T. READ,
Chemical Adviser, General Staff, Department of
the Army.

CHEMICAL ANALYSIS or **ANALYTICAL CHEMISTRY**, that branch of chemistry which aims at finding the composition of any given sample. It is divided into *qualitative analysis*, the purpose of which is merely to find what elements or compounds are present in the sample, and *quantitative analysis*, the object of which is to find the exact percentage or concentration of the various constituents of the sample. A quantitative analysis cannot be performed until the qualitative composition is known. Analytical chemistry may also be divided into inorganic and organic analysis, depending on whether the sample is composed of inorganic or organic substances.

Ultimate analysis is concerned with finding the percentage or concentration of the elements in the sample. *Proximate analysis*, on the other hand, aims to find what percentage of a sample behaves in a certain way under specified conditions. Thus the determination of the percentage of soluble matter in a scouring powder and the determination of ash in coal are examples of proximate analysis.

Analytical chemistry may also be divided according to the size of the sample taken for analysis. Ordinary or *macroanalysis* usually starts with a sample of 0.1 gram to 5 grams. *Microanalysis* requires a sample of only about 0.002 gram. It is applied when the quantity of sample available for analysis is very small, as in biochemical investigation, criminological analysis, and the study of nuclear transformations. It is possible to remove a minute portion of an old masterpiece of painting without marring it and to investigate, by the techniques of microanalysis, the pigments used. Microanalysis is generally less accurate than macroanalysis. In semi-microanalysis, samples intermediate between those of macro- and microanalysis are used. Ultra-microanalysis is an extension of microanalysis into the realm of even smaller samples.

Chemical analysis is applied in almost all manufacturing processes to control the quality of the starting materials, the intermediates, and the finished products. Furthermore it is essential in the chemical and medical research by which new materials such as alloys, paints, lacquers, plastics, rubbers, and drugs are developed.

In industrial analysis, the problem of sampling is important. The manager of a steel mill where a shipload of iron ore has just been received wants to know the percentage of iron in the ore. How can the chemist be sure that the sample taken for analysis is truly representative of the shipload? A good sampling procedure consists in taking systematically one pound of material from each ton as it is unloaded. Thus a *gross sample* is obtained, still far too large to be handled in the laboratory. This is crushed and quartered by piling it into a cone, dividing the cone into quarters and retaining only two opposite quarters. This process of quartering is continued with intermittent crushing or grinding to finer particle size until a sample suitable for laboratory use is obtained.

QUALITATIVE INORGANIC ANALYSIS

Qualitative tests for cations (metallic ions) may be performed by the *wet method*. This means that the constituents are recognized by the reactions that they perform in solution. A traditional procedure for the detection of 24 so-called common cations by the wet method is described in the vast majority of textbooks of qualitative analysis, with only minor variations in procedure among the different books. Unfortunately, the list of 24 cations omits several industrially important metals such as vanadium and molybdenum and also omits the very abundant metal, titanium. A. A. Noyes and W. C. Bray have devised a procedure for the detection of 49 metals (*A System of Qualitative Analysis for the Rare Elements*, London 1927). This procedure is necessarily much more time-consuming than the one designed for only 24 cations.

The first step in qualitative analysis by the wet method is to dissolve the sample. If water alone fails to dissolve the sample, nitric acid or aqua

regia is usually applied. If insoluble material still remains, treatment with hydrofluoric acid or fused sodium carbonate is required.

The usual procedure consists of dividing the metals into seven groups. The addition of hydrochloric acid precipitates the chlorides of lead, mercurous (univalent) mercury, and silver. These constitute the silver group. They are removed by filtration. Treatment of the acid solution with hydrogen sulphide causes the precipitation of the sulphides of eight metals. This precipitate is filtered and treated with ammonium disulphide which dissolves the sulphides of arsenic, antimony, and tin (the arsenic group), leaving the sulphides of mercuric (bivalent) mercury, lead, bismuth, copper, and cadmium (the copper group). Lead appears in two groups because its chloride is too soluble to be completely precipitated with the silver group.

The filtrate from the copper and arsenic groups is then neutralized and treated with ammonium sulphide. Seven metals are precipitated, either as sulphides or hydroxides. After filtration, this precipitate is dissolved in acid and treated with sodium peroxide. Thus the iron group is precipitated (manganese, iron, cobalt, and nickel), while the aluminum group (aluminum, zinc, and chromium) remains in solution.

The filtrate from the iron and aluminum groups is treated with ammonium carbonate and alcohol to precipitate the carbonates of barium, strontium, calcium, and magnesium, which constitute the calcium or alkaline-earth group, while the sodium or alkali-metal group (sodium, potassium, and ammonium) remains in solution.

To analyze the silver group precipitate, the analyst pours some hot water through the filter. This dissolves the lead chloride as a colorless solution and leaves the precipitates of silver and mercury on the filter. The addition of potassium chromate to the filtrate causes the precipitation of yellow lead chromate, which serves as a test for lead. Next, the analyst pours ammonia solution through the filter. If mercurous chloride is on the filter, it is changed to a black mixture of metallic mercury and the compound HgNH_2Cl . The silver is dissolved by the ammonia as a complex ion. Upon the addition of nitric acid to the solution, silver chloride is reprecipitated as a white precipitate.

The space available does not permit a description of the analysis of the copper, arsenic, iron, aluminum and calcium groups. Since the sodium group is quite different from the others, we shall consider it briefly. The unusual feature of this group is the fact that the ions comprising the group form very few precipitates that can serve as tests for the cations. Sodium can be precipitated as sodium magnesium uranyl acetate, $\text{NaMg}(\text{UO}_2)_2(\text{C}_2\text{H}_3\text{O}_2)_6 \cdot 6\text{H}_2\text{O}$, and as sodium antimonate, NaSbO_3 . Potassium can be precipitated as the perchlorate and as a cobaltinitrite. Since ammonium ion forms precipitates with the same anions (negatively charged ions) as potassium, it is necessary to remove the ammonium salts before testing for potassium. This removal is accomplished by taking advantage of the volatility of ammonium salts. The solution is evaporated to dryness and the residue is heated to about 400°C .

The *flame test* is frequently used for sodium and potassium. This depends on the fact that compounds of sodium impart to a colorless flame of a Bunsen burner a brilliant yellow color, while

potassium colors the flame violet. To perform the test, the chemist simply dips a clean platinum wire into the solution to be tested, then holds the wire in the colorless Bunsen flame. The color from sodium is so intense that it obscures the violet color if both sodium and potassium are present. In that case, the chemist observes the flame through a blue glass, which absorbs the rays from the sodium flame but not those from the potassium flame. The flame test may also be used in the analysis of the calcium group. Calcium and strontium have a red flame, while barium gives a green color.

Ammonium ion is always present in the sodium group even though the original sample contained no ammonium salts. This is true because ammonium disulphide and ammonium carbonate are added to the unknown to precipitate the iron, aluminum, and calcium groups. Therefore the test for ammonium ion must be applied to a portion of the original solution. The most sensitive test consists in adding sodium hydroxide to the solution to convert the ammonium ion to ammonia. Upon warming the solution, the ammonia is volatilized. If the vapor is brought in contact with a solution of potassium iodomercurate, K_2HgI_4 , a yellow or brown color is produced.

Before the analyst applies the procedure outlined above, he must test for certain troublemaking anions and remove them if present. Phosphate, for example, may be precipitated as calcium phosphate when the solution is neutralized to precipitate the iron and aluminum groups. Thus calcium would be lacking from its normal group and would be present in the iron group, causing difficulty in the analysis of that group. Citrate and tartrate would prevent the precipitation of aluminum.

Qualitative tests for the anions by the wet method are less systematic than the procedure for the cations. Although several systematic procedures have been proposed, none has been widely adopted. The completion of the analysis for cations along with the knowledge of the solubilities of compounds gives the analyst very valuable clues as to what anions may and may not be present in the sample. For example, if the sample was dissolved completely in water and if silver was found to be present, none of the ions whose silver salts are insoluble in water would be present. These anions include chloride, bromide, iodide, cyanide, sulphide, chromate, and many others. Analogously, the presence of barium in a water-soluble sample proves the absence of sulphate.

In many cases, a complete qualitative analysis of the sample is not necessary, but it is desired only to ascertain whether one specified element is present. In such cases, *spot reactions* are valuable. Suppose, for example, that a chemist wishes to test for nickel in a given solution. He lets one drop of the solution fall upon a filter paper previously impregnated with an organic compound called dimethylglyoxime. If the solution is acid, he neutralizes the acid by bringing the paper in contact with ammonia fumes. If nickel is present, a red spot of nickel dimethylglyoxime is seen where the drop of unknown fell on the paper. A positive test is obtained if the drop contained only 0.00000002 gram of nickel. Spot tests as sensitive and simple as this one for nickel are not available for all of the common elements.

The geologist prospecting for ore will want to know the composition of many of the minerals without sending them back to the laboratory. He

will make use of *blowpipe analysis* in the field. By blowpipe analysis, the minor constituents of a sample are very likely to be overlooked; but the major constituents can be identified by a skilled worker. See BLOWPIPES AND BLAST LAMPS.

The majority of qualitative analyses that are performed in industrial laboratories are done by the *spectrographic* method. This is actually an extension of the simple flame tests mentioned above. In the flame of an ordinary Bunsen burner, about a dozen metals emit a characteristically colored light. In an oxygen-acetylene flame several more metals give such light. If the sample is subjected to more violent excitation in an electric arc or spark, all of the metals give characteristic emissions.

The unaided eye is very limited in its ability to identify a metal by the color of the emitted light for two reasons. In the first place, the color of one metal may obscure that of another. It was previously mentioned that the sodium flame obscures that of potassium. In the second place, the eye fails to distinguish between closely similar colors. For example, calcium, strontium, lithium, and rubidium all emit red light. Both of these difficulties are overcome by using a *spectroscope* to view the emitted light. This instrument separates the light into a spectrum consisting of different lines or bands. Each line has its own color, and each metal has several characteristic lines or bands. The potassium light can be observed even in the presence of more intense sodium light because it appears in a different part of the spectrum. Furthermore, the spectra of calcium, strontium, lithium, and rubidium are distinctly different from each other.

Even better than the spectroscope is the *spectrograph*. This instrument separates the emitted light into a spectrum and then photographs the spectrum. Each metal that was present in the sample is identified in the photograph by its characteristic system of lines and bands. The photograph can be filed as a permanent record of the analysis. Spectrographic methods require very expensive equipment and the services of a skilled operator. Furthermore, they are not applicable to most of the nonmetals.

The advantages of spectrographic methods are as follows: (1) With proper apparatus, they are much more sensitive than the ordinary wet methods. Many metals can be detected in amounts as small as 0.00000001 gram, some in amounts as small as 0.000000001 gram. (2) They are much faster. (3) The photograph frequently reveals the presence of an unsuspected metal for which tests would not have been made by the wet method.

One weakness of all the foregoing methods of qualitative analysis is that they yield information about the metals or the ions that are present in the sample but not about the compounds present. For example, when a sample consisting of sodium chloride and potassium sulphate is analyzed by a spectroscopist, he can report only that the sample contains sodium and potassium. A chemist, after analyzing the same sample by the wet method, can report that it contains sodium, potassium, chloride, and sulphate ions; but he is not able to state whether the sodium is present in the mixture as chloride or sulphate. *Microscopic analysis* enables him to answer this question. By examining the sample under the microscope, he can identify the constituents by the characteristics of their crystals.

X-ray analysis can also be applied to this problem. If a beam of monochromatic X-rays is directed at the sample and if the diffracted X-rays are photographed, the diffraction pattern is characteristic of the compounds in the sample.

QUANTITATIVE INORGANIC ANALYSIS

The methods of inorganic quantitative analysis may be classified under three headings: gravimetric, volumetric, and instrumental.

In *gravimetric analysis*, the sample is usually dissolved, and some solution is added to react with and precipitate the element or radical to be determined. The precipitate is filtered, washed, heated to an appropriate temperature, and weighed. For example, if the percentage of calcium in a specimen of limestone is to be determined, the analyst weighs a sample, dissolves it in hydrochloric acid, adjusts the acidity, and adds ammonium oxalate. Under proper conditions, calcium oxalate monohydrate is precipitated, leaving in solution the magnesium, iron, and aluminum of the sample. He then filters and washes the precipitate, dries it at 105°C., and finally weighs it. From the weight of the precipitate, it is a simple matter to calculate the weight of calcium and hence the percentage of calcium in the sample.

Electrolytic analysis is a subdivision of gravimetric analysis in which the electric current is the precipitating agent. Consider the determination of the percentage of copper in brass as an example. The analyst weighs a sample and dissolves it in nitric acid. He inserts two pieces of platinum (electrodes) into the solution, one connected to the positive terminal of a storage battery, the other to the negative. A rheostat, a voltmeter, and an ammeter are connected in the circuit to facilitate the control of the current. Oxygen is liberated at the positive electrode and metallic copper is deposited on the negative electrode. By weighing this electrode before the determination and again after all the copper is deposited (usually about an hour), the chemist can calculate the weight of copper in the sample.

As an example of *volumetric analysis*, let us consider the determination of the percentage of sodium chloride in a mixture of sodium chloride and sodium nitrate. The analyst weighs a sample and dissolves it in water. He adds a small amount of potassium chromate. He next adds carefully from a buret a solution of silver nitrate whose concentration is accurately known. (This is called a standard solution.) The first portions of silver nitrate react with the chloride to form a white precipitate of silver chloride.

When all of the chloride of the sample has reacted thus, the next drop of silver nitrate reacts with the chromate to give a red-brown precipitate of silver chromate.

The chemist watches for this phenomenon and stops the addition of the silver nitrate as soon as he sees the red precipitate. He then reads the buret to find the volume of silver nitrate solution that has been used to react with the chloride. This volume, together with the known concentration of the silver nitrate, enables him to calculate the quantity of sodium chloride in the sample.

The fundamental process of volumetric analysis is the addition of a solution of known concentration to react with the element to be determined. This is called *titration*. For this reason, volumetric analysis is sometimes called *titrimetric analysis*. It is necessary to stop the addition of the standard solution as soon as the reaction is completed. For this purpose, a compound, called an *indicator*, is added to the solution of the unknown. The indicator causes a change in color when the reaction is complete, or at the *end point*.

The foregoing is an example of a volumetric determination based on a precipitation reaction. Volumetric methods may also be based on neutralization, oxidation-reduction, or complex-forming reactions. An example of a *neutralization* method is the titration of a solution of hydrochloric acid with standard sodium hydroxide.

Phenolphthalein is a good indicator for this titration. It turns from colorless to red at the end point.

An example of an *oxidation-reduction* or *redox* method is the usual procedure for the determination of iron in an ore. The chemist dissolves a weighed sample of ore in hydrochloric acid, treats the solution with some reagent (perhaps metallic zinc) that reduces any ferric iron of the sample to the ferrous state, then titrates with a standard solution of a ceric compound.

Phenanthroline serves as indicator, turning from pink to very pale blue at the end point.

An example of a *complex-forming reaction* is found in the determination of nickel in alloys. The chemist dissolves a weighed sample of alloy in acid, then adds ammonia. If iron or chromium is present, he adds citrate to prevent the precipitation of their hydroxides. The nickel is now present as the nickel-ammonia complex ion. Upon titration with potassium cyanide, it is converted to the cyanonickelate ion.

A small amount of insoluble silver iodide is used as the indicator. It is dissolved by a small excess of cyanide ion after the foregoing reaction is completed.

Thus the end point is marked by the disappearance of the turbidity due to silver iodide.

Volumetric methods are generally preferable to gravimetric methods because they are usually faster and more accurate. However, all chemical elements are not amenable to volumetric determination.

Instrumental methods of quantitative analysis have recently become very important. This term is generally used to include any method of analysis in which a reasonably complicated instrument, other than the balance and buret, is used.

The spectrograph, in addition to its use in qualitative analysis, can also serve for the quantitative determination of metals. Thus the appearance of two lines in the photograph corresponding to wavelengths of 589.6 and 589.0 millimicrons serves to indicate the presence of sodium in the sample. In addition, the intensity of these lines can be compared with the intensity of the same lines in the photographs obtained with

samples of known sodium content to find the content of sodium in the unknown sample. For the quantitative application of spectrography, all the experimental conditions such as the intensity of the excitation, the duration of the exposure, and the conditions for the development of the photograph must be the same for the unknown sample as for the standard samples. Even with these precautions, the spectrographic method is less accurate than gravimetric or volumetric methods except for the determination of trace constituents.

In contrast to spectrography, where the light emitted by the sample is measured, there are several analytical techniques that depend on the measurement of the light absorbed by the sample. These are called *photometric methods* or *colorimetric methods*. The essential feature is that the constituent to be determined must absorb light. If the absorption occurs within the range of visible wavelengths, the constituent is "colored"; but equally satisfactory photometric determinations of a "colorless" constituent can be performed if this constituent absorbs ultraviolet light. There is also the possibility of changing the constituent to be determined from a colorless to a colored form. For example, when manganese is determined photometrically, it is converted to the intensely purple permanganate ion.

In the simplest photometric procedures, the intensity of color of the solution of the unknown sample is compared visually with the intensity of color of standard solutions. In general, more satisfactory results can be obtained by using photometers. In these instruments, the solution to be investigated is placed between a steady source of light and a photoelectric cell, which measures the intensity of light that passes through the solution. From this measurement, the chemist calculates the concentration of the light-absorbing constituent. Monochromatic light is used in photometers. If a prism and slit are used to exclude all the wavelengths except the desired one, the instrument is called a spectrophotometer. If the undesired wavelengths are eliminated by passing the light through a colored glass, the instrument is called a filter photometer.

When light is passed into a suspension of a solid material in a liquid, some of the light is reflected or refracted into a path at right angles to the original beam. If this scattered light is measured with a photoelectric cell, we have a *photoelectric nephelometer*, which can be used to measure the concentration of the suspended solid. Nephelometry is frequently used to determine small traces of chloride after converting it to insoluble silver chloride. Nephelometry is less accurate than the photometric methods that depend on the absorption of light.

Fluorescent compounds have the ability to absorb light of one wavelength and to use the energy thus gained to emit light at a longer wavelength. The concentration of a solution of such a compound can be determined by measuring the intensity of the light emitted at right angles to the exciting beam. The *fluorophotometer* used for this purpose is very similar in design to the nephelometer.

Flame photometers are instruments for determining the concentration of those metals that emit light when introduced into a flame. The solution is atomized by a stream of air and swept into a flame. The light imparted by the metal is measured with a photoelectric cell. Interference

from other metals that color the flame can usually be eliminated by using a prism and slit or light filter to eliminate the undesired wavelengths. Very careful standardization is necessary if reasonable accuracy is to be obtained by this method.

In addition to the foregoing optical methods of instrumental analysis, there are numerous *electrochemical* methods. Many of these are adjuncts of volumetric analysis and serve merely to locate the end point in titrations.

In *potentiometric titrations*, two electrodes are inserted into the solution to be titrated. One is called a reference electrode and is usually a saturated calomel electrode. The other is called the indicator electrode. For redox titrations, the indicator electrode is platinum; for precipitation and complex-forming titrations, usually silver; for neutralization titrations, usually "glass" or "hydrogen." The analyst measures the electromotive force between the electrodes as the titration is performed. A sudden increase or decrease in this electromotive force marks the end point of the titration.

Instruments are now on the market in which the electromotive force at the end point activates a relay that turns off the buret. Thus the chemist is freed for other work during the actual titration. Aside from this rather novel aspect of potentiometric titrations, they possess two practical advantages over titrations with indicators: (1) In many cases they are capable of greater accuracy. (2) They can be used to titrate highly colored solutions where the color change of an indicator could not be observed.

In *conductometric titrations*, two electrodes of platinum black are immersed in the solution to be titrated, and the conductance (or resistance) of the solution is measured at several points during the titration. The conductance is plotted against the volume of titrating solution added. A sudden change in the direction of the graph marks the end point. Conductometric titrations are less accurate than indicator or potentiometric titrations except in the titration of very weak acids. They are useful for colored solutions and for those titrations for which there are no satisfactory indicators or indicator electrodes.

An alternating current of about 1,000 cycles per second is ordinarily used in conductometric titrations. If the frequency is increased to about 1,000,000, the technique is called *high-frequency titration*. Then the electrodes can be placed outside the solution on opposite sides of the containing beaker. The curves have different shapes, but the end points are still marked by a sudden change in direction. The theory of high-frequency titrations is not well understood, but the dielectric constant of the solution as well as its conductance enters into the measurements.

Polarographic analysis is one of the important electrochemical techniques. Mercury is allowed to drop from a reservoir through a capillary tube that is immersed in the solution to be analyzed. The rate is controlled at about 20 or 30 drops per minute. The dropping mercury is made the negative electrode, while the pool of mercury that collects in the bottom of the vessel, or preferably a saturated calomel electrode, is the positive electrode. The electromotive force between the two electrodes is gradually increased, and the current flowing through the solution is read at frequent intervals. A graph is plotted showing the relationship of the current to the electromotive force. This graph ordinarily shows a sudden

steplike rise for each reducible constituent of the solution. The rise caused by any particular reducible solute always occurs at the same electromotive force. The height of the rise is proportional to the concentration of the solute being reduced. Thus the graph serves to determine the concentration of the solute in question. Polarographic methods are less accurate than volumetric or gravimetric methods except for the determination of trace amounts. In *amperometric titrations*, the polarographic technique is used to locate the end point.

Radioactive isotopes are sometimes used in testing the accuracy of a method, in locating the sources of error in a method, and in performing rather unusual determinations. Their use in routine analysis is limited by the precautions and special techniques that are required.

The accuracy of inorganic quantitative analysis varies greatly with the constituent to be determined and the presence or absence of interfering constituents in the sample. A skilled analyst can determine the percentage of copper in brass by the electrolytic method with an error smaller than 0.1 per cent. On the other hand, the gravimetric determination of the percentage of silica in limestone, clay, glass, or refractory is subject to errors of several tenths of one per cent.

Consult Kolthoff, I. M., and Sandell, E. B., *Textbook of Quantitative Inorganic Analysis* (New York 1941); Dean, J. A., Mettrick, L. L., Jr., and Willard, H. H., *Instrumental Methods of Analysis* (New York 1948); Rieman, W., Neuss, J. D., and Naiman, B., 3d ed. (New York 1951).

QUALITATIVE ORGANIC ANALYSIS

The purpose of the qualitative analysis of an organic substance may be to identify the elements or the compounds present in the sample. If the former objective is sought, the organic substance is decomposed so that inorganic compounds of the constituent elements are formed. This may be accomplished by heating some of the unknown with metallic sodium. Thus sodium cyanide, sulphide, and chloride are found if the unknown contains nitrogen, sulphur, and chlorine, respectively. Ordinary inorganic qualitative tests are then used to identify the products of the decomposition.

The identification of the compound or compounds in the sample is a more difficult task. If the sample has a constant boiling point and melting point, it probably contains only one compound. Then the analyst's task is to identify this one compound as one of the many thousands of known organic compounds. The sample is classified into one of the groups of organic compounds by noting its solubility in water and in various aqueous solutions, also its reactions with reagents such as bromine, alcoholic silver nitrate, acetyl chloride, nitrous acid, and phenylhydrazine. Finally the measurement of its physical properties such as density, refractive index, boiling point, and melting point serves to identify the compound.

If the sample is a mixture of two or more compounds, the task is more involved. It is first necessary to separate the compounds from each other. This may be accomplished by taking advantage of differences in their boiling points (by fractional distillation) or differences in their solubilities (by extraction or fractional crystallization). Finally, the isolated and purified compounds are identified as outlined above.

Consult Fuson, R. C., and Shriner, R. L., *The Systematic Identification of Organic Compounds*, 2d ed. (New York 1940).

QUANTITATIVE ORGANIC ANALYSIS

If a quantitative ultimate analysis is desired, the *combustion method* is generally applied. For the determination of carbon and hydrogen, a weighed sample contained in a porcelain or platinum boat is put into a tube of silica or high-melting glass. Oxygen is passed into the tube, and the sample is heated. The tube also contains cupric oxide to aid in the oxidation. Thus the carbon of the sample is converted to carbon dioxide and the hydrogen to water vapor. If the sample contains compounds of chlorine, sulphur, or nitrogen, lead dioxide is also put into the tube to retain these elements as lead chloride, sulphate, and nitrate. Thus the gases issuing from the other end of the tube contain only water vapor, carbon dioxide, and excess oxygen. These gases are passed first through a weighed tube containing anhydrous magnesium perchlorate or other drying agent, then through a weighed tube containing solid sodium hydroxide. The first tube absorbs the water, and the second tube absorbs the carbon dioxide. The gain in weight of these tubes is a measure of the hydrogen and carbon, respectively, in the sample.

For the determination of chlorine and sulphur, a different type of combustion tube is used in which hot platinum acts as a catalyst for the oxidation, replacing the cupric oxide. The gas issuing from such a tube contains the chlorine as hydrogen chloride and the sulphur as sulphur trioxide. These substances are absorbed by passing the gas through suitable solutions, and then determined by an ordinary gravimetric or volumetric method.

Nitrogen in an organic sample may be determined by the Kjeldahl method or by the Dumas method. The *Kjeldahl method* is the simpler procedure and yields accurate results unless the nitrogen is present as nitrile groups or in heterocyclic compounds. In this method, the weighed sample is heated with concentrated sulphuric acid. Thus the nitrogen is converted to ammonium ion, which is determined by a neutralization titration.

In the *Dumas method*, the weighed sample is mixed with cupric oxide and heated in a tube containing both cupric oxide and metallic copper. The nitrogen is converted to elementary nitrogen, a gas. This is swept from the combustion tube by passing carbon dioxide through the tube. The effluent gases are bubbled through a solution of potassium hydroxide, which absorbs the carbon dioxide. The residual volume of pure nitrogen is measured.

Although several methods have been proposed for the determination of oxygen in organic substances, none is entirely satisfactory or widely used. The usual method for this determination is to find the percentages of all other elements in the sample and to subtract the sum from 100.

Ultimate organic analysis is frequently done on the micro scale. For details consult Niederl, J. B., and Niederl, Victor, *Micromethods of Quantitative Organic Elementary Analysis* (New York 1938).

The determination of the percentage of one compound in a mixture of organic compounds is ordinarily a difficult task. Space will permit only the brief mention of a few of the possible approaches to this problem.

If the sample to be determined is an acid or a base and if interfering acids or bases are not present, a simple neutralization titration will suffice. This may often be profitably performed in

some organic solvent rather than in water. Titration with an oxidizing agent such as a ceric compound may be successful in the determination of a reducing compound if other reducing agents are not present in the sample. Titration with a reducing agent such as titanous sulphate is used to determine nitro compounds and some dyestuffs. Iodic acid reacts only with compounds that contain hydroxyl groups on two adjacent carbon atoms and can be used for the determination of such compounds.

Photometric methods are often applicable. Infrared photometry is also used. Some organic compounds such as nitro compounds and aldehydes can be determined polarographically. Sugars and some other organic compounds have the property of rotating the plane of polarized light, the degree of rotation being proportional to the concentration. Thus a measurement of this property with a *polarimeter* can be used to determine such a compound provided that other compounds with this property are not present in the sample.

Volatile samples may be analyzed by the *mass spectrometer*. A small amount of the sample is admitted into an evacuated chamber and bombarded there with a stream of electrons. These decompose the compounds into charged fragments (ions). A large velocity is imparted to these fragments by an intense electrical field. As these ions sweep through the tube they are subjected to a magnetic field at right angles to their motion. This deflects them from their original direction, and the light ions are deflected more than the heavy ones. Thus the spot on the end of the tube which a given ion hits depends on its weight. By measuring the number of ions that hit different points, the quantity of ions of any given weight can be determined. These data permit the operator to calculate the composition of the sample. This technique is very important in the analysis of gasoline.

ANALYTICAL SEPARATIONS

In any quantitative analysis, whether the sample is organic or inorganic, whether the final determination is to be done gravimetrically, volumetrically, or instrumentally, the analyst is liable to encounter the difficulty of finding in the sample some constituent that interferes with the determination of the desired constituent. For example, in the electrolytic determination of copper, silver would be deposited on the negative electrode along with copper and hence would interfere. Again, the presence of titanium introduces an error in the volumetric determination of iron, as previously outlined, because the reaction

would also occur during the titration. In some cases the interference can be avoided by selecting a different method of determination. For example, aluminum interferes in the gravimetric but not in the volumetric determination of iron. In other cases the analyst has to remove the interfering constituent before the determination can be performed. A brief description of the methods for such separations follows.

Distillation and extraction, which have already been mentioned as methods of separating organic compounds, are also used in inorganic analysis. Boron is frequently separated from interfering elements by distillation. Iron can be separated from most other cations by shaking the aqueous solution containing hydrochloric acid with isopropyl ether. The ferric chloride dissolves in the

ether, leaving the other metals in the aqueous solution.

The *precipitation* of a single compound or of groups of compounds is frequently used for separations but is seldom entirely satisfactory. The precipitate is always contaminated with the compounds or ions that would normally remain in solution under the given conditions. This phenomenon is called *coprecipitation*.

Electrolytic separations are simple and effective in some cases. If the solution is electrolyzed with a platinum anode and mercury cathode, metals such as lead, cadmium, copper, and silver are dissolved in the mercury while the ions of other metals such as calcium, magnesium, and sodium remain in the aqueous solution.

Chromatographic methods have recently been used to accomplish some very difficult separations. In *adsorption chromatography*, a vertical tube, open at both ends, is filled with a solid adsorbent, frequently alumina. The substances to be separated are dissolved in a small volume of some solvent, usually nonaqueous, and poured into the tube. Additional solvent is slowly poured into the tube. The solutes usually have different affinities for the adsorbent, so that they move down the tube at different rates and issue from the tube in different fractions of the effluent.

The procedure of *partition chromatography* is analogous except that the tube is usually filled with moist starch or silica gel and the separation is achieved by pouring an organic solvent through the tube. In *ion-exchange chromatography*, the tube is filled with an ion-exchange resin. The sample is added in aqueous solution, and the liquid used to cause the separation is an aqueous solution of a suitable salt. In *paper chromatography* one small drop of a solution of the substances to be separated is placed on a strip of paper. Liquid is allowed to trickle slowly down the vertically held strip, thus separating the solutes.

WILLIAM RIEMAN III,
Professor of Analytical Chemistry, Rutgers University.

CHEMICAL APPARATUS. To gain a general idea of chemical laboratory apparatus and equipment, the reader is asked to join an imaginary tour of a large university laboratory.

The Beginners' Laboratory.—The first door that is opened admits to a room in which a class is beginning the first laboratory exercise of the elementary course. The students are distributed along *laboratory tables* or *desks*. These desks have tops of soapstone or acid-proof wood below which are drawers and cabinets in which apparatus is stored. Above the tops are narrow shelves for *bottles* containing chemicals in constant use. Beneath the bottle racks are pipes for water and gas, and conduits for electrical wiring. *Sinks* of stoneware are set into the desk tops at intervals. Along the walls are several tables on which are placed cabinets of asbestos board and glass sash connected with ventilating ducts. These are the *hoods* through which fumes are removed. The remaining wall space is lined with shelves filled with bottles of several types. Those containing liquids have relatively small necks and are closed by glass stoppers, by plastic screw caps, or by rubber stoppers. Those filled with solids have larger necks. All bottles in permanent use have either enameled labels fused on them or raised letters and figures cast as the bottle was made.

The task in which this group of students is engaged is the making of a "wash bottle." A *Florence flask* is best adapted to this purpose. It has a fairly long neck and a flat bottom, but its general shape is globular. A glance into an open desk will reveal several *Erlenmeyer flasks* with flat bottoms and walls that taper from the greatest breadth at the bottom up to a short neck. The *round bottom flask* more commonly employed in advanced courses is somewhat less likely to break when heated, but must always be supported by rings or clamps when in use.

The student is supplied with a collection of *rubber stoppers*, and selects one of the proper size which is made with two holes through it. For certain uses it is necessary to start with a solid rubber stopper or with a *cork stopper* and bore the desired holes. A *cork borer* is essentially a brass tube with a handle at one end. The other end is beveled to a sharp edge and the hole is made by pressing and twisting the borer through the stopper. If a hole is being made through rubber, the borer is moistened with water. An experienced manipulator will bore

only part way from one end of the cork, and then will start the hole from the other end and so gauge distances that a smooth hole results. The plug that is removed has to be pushed out of the borer by a rod. The next step is to cut, bend, and draw *glass tubing* to the proper shape and dimensions. Glass tubing is furnished in lengths up to about five feet and must be cut to shorter lengths. This is done by making a light mark with a *triangular file* at the proper point and applying gentle pressure on each side of the mark. The edges at the break are sharp and must be rounded by holding the ends of the tubing in a gas flame until the glass softens. The gas flame is from a *Bunsen burner*. This is essentially a metal tube held in a base of some sort into the lower end of which a stream of combustible gas enters through a small orifice regulated by a valve. Air is admitted at the same time through holes in a collar around the tube, which is similarly perforated. The air serves to cool the interior of the flame and to prevent the premature decomposition of some of the components of the

gaseous fuel with the formation of incandescent carbon particles. (A still hotter flame is produced by admitting air or oxygen under pressure in a *blast lamp*.) The flat shape of the flame employed in drawing and bending glass results from a flattened *wing tip* which is temporarily attached to the top of the burner. One piece of glass is heated and drawn so that the two portions of normal diameter are connected by a constricted portion. By cutting in the middle of the constriction, a tip for the wash bottle is obtained. Two other pieces of glass are bent in the flame, one to an acute and the other to an obtuse angle. The former is of sufficient length to reach nearly to the bottom of the flask, while the portion of the other that is beyond the bend is only long enough to extend part of the way into the neck of the flask. The two pieces of glass are wetted with water and gently forced through holes in the rubber stopper. The tip is attached to the tube coming from the bottom of the flask by a piece of *rubber tubing*, and the wash bottle is ready to be filled with water or other liquids. To cause water to flow from the bottle, the user blows into the tube with the obtuse angle. Water rises in the other tube and escapes through the tip. Since this is connected with a flexible rubber tube, the stream of water may be directed where it is needed.

Detection and Identification of Substances.

—The visitor next comes to another laboratory where students are detecting and identifying various substances. Here is a student who has just received from his instructor a small stoppered flask containing a clear liquid. Some of this is poured into a *test tube*, which is merely a thin-walled glass tube with one rounded closed end and a small flaring lip at the other end. Several of these tubes are in a wooden *test tube rack* on the desk. To the liquid in the tube the student adds a few drops from a reagent bottle. The contents of the tube change in appearance to resemble milk. The tube is picked up by a *holder*, which is made of heavy wire so bent that when the handle portion is squeezed the wire loops functioning as jaws open, and when pressure is released the jaws hold the tube tightly. By means of this holder the tube may be placed in the upper portion of the flame from a Bunsen burner, this time without the wing tip. If the tube were held upright, the steam generated at the bottom would throw out the liquid above it. It is properly held in a slanting position and heat is applied a little below the upper surface of the liquid. As heating is continued, the milky appearance of the liquid changes, and there is definite separation of solid and liquid portions. The student has previously placed a *glass funnel* with a long stem in another test tube. Into this funnel he has folded a piece of circular *filter paper* so

that it forms a cone fitting the funnel closely. The contents of the first tube are poured slowly into the funnel. The solids remain on the paper, and a clear liquid runs out of the stem of the funnel.

This operation of filtration may be modified in a number of ways. A small porcelain *filter disk* may be laid in the funnel and its perforations covered with a small disk of filter paper. Instead of depending on gravity, the funnel may be passed through a rubber stopper and placed in the neck of a *suction flask* the side arm of which is attached to a *vacuum pump*. Thus the pressure of the atmosphere forces the liquid through the filter medium. For separation of larger quantities of solids, the *Büchner funnel* functions in much the same way as a funnel and a disk, being a porcelain funnel with a perforated disk permanently sealed in it.

Another student has gone to a hood, attached a short length of glass tubing to a *Kipp generator*, and is passing a slow stream of gas through a liquid in a test tube. This gas generator appears at first glance to be made up of three superimposed bulbs, the lowermost one having a flattened base, and the uppermost having a neck like that of a flask. Closer examination reveals that the uppermost bulb terminates in a long tube that reaches almost to the bottom of the apparatus. The middle and lowermost bulbs are connected by a short cylindrical section through which the tube from the topmost bulb passes. Lumps of a solid are packed around the tube in the middle bulb, but are not small enough to pass through the annular space between the tube and the constricted section between the two bulbs. There is a gas outlet equipped with a valve in the upper part of the middle bulb. A liquid fills the bottom bulb and partly covers the solids in the middle bulb. Chemical action produces a gas, which escapes through the valve. When sufficient gas has been drawn off to complete the test, the valve is closed. Gas pressure forces the liquid up the tube into the upper bulb until it is drained from the lumps of solid. Chemical action then ceases and the generator is ready for use again.

Still another student is testing a solid substance by heating it in a depression in a lump of charcoal by means of a *blowpipe*. This is merely a metal tube with ring lip at one end and a small jet orifice at the other. A tip somewhat similar to the wing tip is placed on top of the Bunsen burner, the chief difference being that it has a slanting orifice. The blowpipe is placed just outside or within the flat flame, depending on the chemical action desired, and a steady jet of flame is directed against the substance on the charcoal. This requires some skill on the part of the operator. The cheeks are continually inflated so that breathing does not interfere with a continuous blast of air through the blowpipe.

Organic Preparations.—In the next room chemical compounds are being made in larger quantities. Here is a preparation in its first stage. Substances have been mixed together in a round-bottomed flask and are now in solution. The flask rests on a square of *wire gauze* supported by a *ring* the side rod of which is held by a *clamp* to the upright rod of a *ring stand* base. The flask is being heated by a burner of the same type as those previously seen. Flasks are often supported on *tripods*, which are rings fitted with three legs. Projecting through a stopper into the neck of the flask is a *condenser*, which is being operated

in the "refluxing" position. A condenser is essentially a long glass tube tapering slightly at the lower end and flaring into larger diameter at the upper end. Around the central portion of this tube is another larger tube held at its constricted ends by pieces of rubber tubing to form a jacket around the inner tube. In many condensers this jacket is permanently sealed on the inner tube by the fusion of the glass. Water flows into the jacket through a tube sealed on near its lower end and escapes through another side tube near the upper end. The water is fed in and escapes through rubber tubing. The contents of the flask are boiling briskly, and the vapors pass up into the cooled inner tube of the condenser. There the lowered temperature converts them to a liquid again, which drops back into the flask.

Another worker has gone still further with this preparation and is now pouring the cooled liquid from the flask into a *separatory funnel*. The upper part of this piece of apparatus resembles a round flask with a short, glass-stoppered neck, the lower part an ordinary funnel with a valve connecting it with the stem. Another liquid is poured into the separatory funnel, and it is seen that the two liquids do not mix. The stopper is put in, the funnel is inverted, and any gas that has formed is vented through the stem. Then the funnel is thoroughly shaken and set upright in a ring on a stand. When the contents separate into two layers, the lower layer is drawn off, the stopper being removed to permit entrance of air. The purpose of this operation is to extract a substance from the first liquid by means of a second liquid in which it is more soluble and in which other substances in the first liquid are not appreciably soluble.

Final purification of the substance desired is brought about by distillation. The simplest apparatus for this purpose is a *distilling flask* an ordinary round-bottomed flask with a long neck to which an inclined side-arm tube is sealed. A *thermometer* passes through a stopper and is so adjusted that its bulb is just below the side-arm tube. This tube passes through a stopper into the upper end of a condenser, which this time slopes downwards. The lower end of the condenser passes into a receiving flask. The whole apparatus is supported by ring stands and clamps. As the impure liquid is heated, the vapors of the pure material rise, pass through the condenser, and are converted to a liquid, which drips into the receiver. The thermometer reading indicates the boiling point of the pure liquid. This represents the most elementary form of distillation. If a mixture of two liquids of different boiling points is to be separated, a *distilling column* is employed. This may either be the very long neck of the flask or a tube attached to the flask. Its inner surface is greatly increased by being filled with beads, bulbs, or coils of wire. A certain portion of the vapors is condensed and returned as "reflux." In this way the higher-boiling material is returned to the flask, while the more volatile liquid escapes into the final condenser.

A *Claissen flask* is often substituted for the ordinary type of distilling flask in vacuum distillation of liquids of high boiling point that tend to decompose at higher temperatures. This flask has a round bottom and a short neck which branches into two vertical tubes or necks. One is a continuation of the original flask neck, while the other is connected at a right angle and is then bent again to a vertical position. The delivery

tube is on this second neck, which also contains the thermometer. A glass tube, drawn at the end to a fine capillary, passes down through a rubber stopper in the first neck nearly to the bottom of the flask. A fine stream of air bubbles, drawn in by the vacuum through this tube, serves to keep the liquid stirred and boiling smoothly.

For many purposes a simple injector attached to the water supply suffices as a vacuum pump. For lower pressures a motor-driven *oil pump* equipped with vanes or gears is necessary. Many laboratories have a system of piping which leads to a large pump that provides vacuum service all over the building.

Instead of employing a direct flame under a wire gauze or a *sand bath* (a flat pan containing a thin layer of sand), heat may be applied through boiling water in a *water bath* (a pan with a top made up of concentric rings to fit the flask used), or a *steam bath* (a funnel with similar type of top and fed with steam). Electric resistance heaters, either with flat tops or with depressions that fit the proper flask, are also commonly employed in such laboratories. Another type of *flask heater* is a globular bag of woven glass thread equipped with a zipper and containing imbedded resistance wire for electric heating.

Quantitative Analysis—Gravimetric.—The next laboratory is devoted to the determination of the quantities of substances that are present in synthetic or natural products. Just now the class is analyzing a rock, and the quantity of silica in it is being determined. One worker is grinding a sample of the rock to a fine powder in a *mortar* by means of a *pestle*. The mortar is a thick-walled, shallow vessel made of agate. Ordinary mortars are somewhat deeper and are made of some sort of porcelain ware. The pestle is essentially a thick and slightly tapering rod with rounded ends, and is of the same material as the mortar. Soft materials may be ground with mortar and pestle alone, but harder rocks must be handled in special grinding equipment of alloy steel until small particles result. Grinding is continued in a mortar until the powder passes through a fine-mesh *sieve*.

A portion of the powder is then weighed on an *analytical balance*. This piece of equipment is necessary in all analytical laboratories. In common with the crudest of weighing devices it is made up of a beam suspended at its middle point and two pans flexibly attached to the ends of the beam. The analytical balance, however, is much more complicated and delicate. The beam is supported by a steel or agate knife edge on a plate of similar material which is at the top of a vertical post. The pans hang from stirrups which are equipped with knife edges and plates. The beam has a long vertical pointer which reaches down to a graduated scale at the base of the post supporting the beam. Supports lift the beam and the pans when the balance is at rest, and can be lowered gradually during weighing operations. This enables the operator to ascertain which pan is more heavily loaded, and to adjust weights until the two pans are almost evenly balanced. Then the beam is allowed to swing slightly and the deflections of the pointer are noted on the scale. The larger *weights* are brass cylinders with stems, and are often plated with nickel, platinum, or gold. The smaller weights are thin square plates with an upturned edge or corner, the more expensive ones being made of platinum. Weights are not touched by

the hands, but are handled by brass *forceps* tipped with bone or plastic material. Final adjustment is made by placing a *rider* on the graduated beam and moving it to the proper position as indicated by the deflections of the pointer. A rider is a piece of aluminum or platinum wire with a loop in the center and two downward sloping ends. It is handled by means of a sliding hook. The entire mechanism is enclosed in a glass case with sliding doors. The usual chemical balance has a capacity of 200 grams and can detect differences of .0001 gram or .1 milligram. Special types of balances such as those used in assaying and in micro-analysis are still more delicate and sensitive.

The sample of material to be analyzed is either placed in a glass-stoppered, thin-walled weighing bottle from which necessary amounts are removed, or it is spread on a *watch glass*, a shallow glass dish of the shape of a watch crystal. To avoid additional weighings, it is common practice to balance one watch glass with another of exactly the same weight on the other pan of the balance, the weights being laid on the glass rather than on the balance pan. Portions of the sample are added or removed from the watch glass by means of a *porcelain spoon* or a *stainless steel spatula*. A spatula is a flat blade with rounded ends and a handle.

The weighed sample is dried in an *oven* heated by burning gas, or more commonly by an electric current. The latter type of oven can be more accurately controlled, expanding and contracting metal contacts turning off and on the current to maintain the temperature between the

desired limits. To avoid absorption of moisture on cooling, the sample and its container are placed on a perforated plate in a covered vessel called a *desiccator*. Below the plate there is a substance such as sulphuric acid, calcium chloride, or phosphorus pentoxide, which absorbs water vapor.

In order to render the sample of rock powder soluble, a weighed amount is mixed with sodium carbonate and fused in a platinum *crucible*. The usual crucible has a flat bottom, circular cross section, and curved sides, and is fitted with a lid that has a short projection at one side for a handle. Crucibles are handled by *tongs* of brass or nickel, some being shod with platinum at their tips. The fused mass is cooled and dissolved in an acid solution, the crucible and its contents being placed in a *beaker*. A laboratory beaker is a thin-walled cylinder with a flat bottom that curves at its edges to join vertical walls. It is commonly somewhat deeper than it is wide, is flared slightly at the top, and at one point on the rim has a small lip like that of a pitcher to facilitate pouring. A beaker is usually covered by a watch glass. A thin glass *stirring rod* with rounded ends is placed in the beaker so that it projects from under the cover glass through the lip. Heating is accomplished on a wire gauze above a burner or on an electrically heated plate. The crucible is removed, when solution is complete, and is washed by a stream of water from the wash bottle, being handled by the stirring rod. The solution of the sample is transferred to a shallow *vaporating dish* with a rounded bottom and a pouring lip. In the analytical laboratory such dishes are often made of platinum, but for most purposes porcelain dishes are satisfactory. Evaporation is accomplished in this case in a water bath. Evaporation is often carried out in a deeper dish that is called a *casserole*, a term familiar to housewives. The dry residue in the dish is moistened with acid and is again dried on the water bath. After the addition of water, the silica is obtained in the form of a jelly-like solid. The contents of the dish are poured into a funnel lined with filter paper, the lip of the dish being held against a stirring rod which is placed vertically over the funnel. A constriction in the stem of the funnel accelerates the speed of filtration by permitting the formation of a column of liquid in the lower part of the stem.

After the removal of as much as possible of the suspended solid to the funnel by a stream from the wash bottle, a rubber-tipped rod called a *policeman* is rubbed over the inside of the dish to loosen any adhering material, and this is in turn washed out of the dish. The funnel is held in a rack or *funnel stand*, which is often made of wood. The liquid which passes through the paper is caught in a beaker.

When the solid substance on the filter paper has been washed free of dissolved material, the paper and its contents are transferred to a weighed porcelain or platinum crucible. The paper is dried and burned as the crucible is suspended over a flame in a *wire triangle*. If the wire is of iron, it is usually protected by tubes of fireclay or fused silica, but platinum and nickel-chromium triangles do not require such protection. The crucible may also be placed in an *electric furnace* lined with fireclay and heated by resistance coils. After the paper has burned, leaving a negligible amount of ash, and all water has been driven off, the crucible is cooled down to about the temperature of boiling water and

is placed in a desiccator to be further cooled. The weight of the contents of the crucible is obtained and recorded. This is a typical gravimetric determination.

Precipitates that need to be heated only to moderate temperatures in an oven may be handled in a *Gooch crucible*. This has uniformly and slightly sloping walls and a perforated flat bottom. It is attached by means of a short piece of rubber tubing to a glass tube whose constricted lower end passes through a rubber stopper into a suction flask. A suspension of asbestos fibers in water is poured into the crucible as suction is applied until a thin filter mat is formed, which will retain most precipitates satisfactorily.

Quantitative Analysis—Volumetric.—Passing on to another laboratory, also devoted to analytical work, the visitor will see tests made by the measurement of liquids. An exactly weighed amount of a compound is dissolved in water and is transferred to a *volumetric flask*. This resembles a Florence flask, but has a longer and thinner neck and is equipped with a glass stopper. On the neck is an etched ring which indicates that when the flask is filled exactly to this mark, it contains a certain definite amount of liquid. The weight of the dissolved material is known, and when water is added until the mark is reached, the volume of the solution is known (For many purposes liquids may be measured in a *graduated cylinder*, but in analytical work more accurate methods are required.)

Smaller portions of such a solution are delivered from a *buret*. This is a long glass tube to which is attached a glass valve known as a stopcock and a tip drawn out so that the liquid will flow out drop by drop or in a very thin stream depending on how far the valve plug is turned. The tube has graduations, beginning shortly below the top and extending down nearly to the stopcock, which indicate how much liquid has been drawn off. A typical buret has a capacity of 0.5 liter or 50 milliliters between the uppermost and lowermost marks, and it is possible to read and estimate to .01 milliliter. A *pipette* is a small tube with an enlarged section about midway between the two ends, the lower end being constricted at its tip. A mark on the upper end of the pipette indicates its capacity when filled by suction to this mark. Safety regulations forbid direct mouth suction on filling pipettes unless the liquids are harmless. It is common practice to draw liquid in somewhat above the mark and allow it to run out until the level sinks to the mark. The rate of flow is controlled by placing a finger above the upper end, lifting and pressing as required. Pipettes are generally used to deliver a fixed amount of liquid, although some are of uniform bore and are graduated like a buret.

In a volumetric analysis a weighed amount of substance dissolved in some liquid or a measured volume of liquid in a dish, flask, or beaker is placed under a buret and the testing liquid of known concentration is run in with stirring until there is a definite change of color in the mixed liquid. Instead of depending on a change of color, many determinations are made by adding the testing liquid in small portions and, after each addition, measuring the voltage that is set up between the liquid in the container, into which an electrode dips, and another half cell of known value. The two half cells are connected by means of a solution in an inverted U-tube dipping below the surfaces of the liquids in the two. Such de-

terminations require the use of a complex piece of electrical equipment known as a *potentiometer*.

The substances present in a gas are commonly determined by measuring the shrinkage in volume of a sample of the gas as one substance after another is removed from it as it is passed over absorbing solutions in *gas pipettes* and back into a *gas buret*. The quantity of certain gases evolved as the result of reactions between the weighed sample and appropriate chemicals is often accurate measures of the amounts of substances that are being determined. Quite often the quantity of a gas absorbed is determined by weighing the absorbing vessel before and after passage of the gas through it. Carbon compounds are commonly analyzed by burning them in a hard glass or silica tube in a *combustion furnace*, usually electrically heated. A current of oxygen sweeps the products of combustion through a weighed *absorption bulb* which retains them and permits the escape of unused oxygen.

This method is employed in the rapid determination of carbon in steel.

Special Types of Equipment.—A great many special types of equipment are found in chemical laboratories, each type having a specific and definite purpose. For example, one collection of tubes, stirrers, cooling bath, and thermometer makes up a *freezing point apparatus*. A somewhat similar assembly with heating facilities and condenser constitutes a *boiling point apparatus*. By weighing a bottle of special shape fitted with a long, perforated glass stopper and known as a *pycnometer*, filling it with liquid, forcing out the excess of the liquid by inserting the stopper, wiping it dry, and weighing it again, it is possible to determine the exact density of the liquid. The capacity of the bottle is found by filling it with a liquid of known density such as water.

Instruments are increasingly important in chemical laboratories, and this is particularly true in industrial work. The refractive index is a measure of the extent to which a beam of light is bent as it passes through a transparent substance. This is a property of each individual substance by which it may be identified and es-

timated, measurement being made by a *refractometer*. Certain substances twist the plane of vibration of polarized light as it passes through them. The extent of rotation is measured by a *polarimeter*. In the sugar industry the instrument is graduated to read directly the percentage of sugar and is called a *saccharimeter*. The extent to which light is obscured in its passage through a suspension of finely divided solids may be measured by a *nephelometer* and the results indicate the quantity of solids present. A *colorimeter* measures quantities of colored material by comparison with known standards. The light from solid substances that are heated to incandescence, when passed through a prism, is broken up into a series of lines, which may be photographed and thus recorded. The instrument in which this operation is carried out is a *spectrograph*. It not only detects various elements but gives a fair idea of their quantities. The crystalline form and optical properties of solids are observed and determined by the *microscope* (q.v.). These are typical instruments employed in a chemical laboratory.

Many of the operations described are duplicated on a larger scale in the chemical engineering laboratory or in the semiworks or pilot plant of an industry. However, the equipment employed is often quite different and resembles more closely that of a large plant. In many cases larger equipment accomplishes results that are difficult or impossible in laboratory apparatus. For example, a large, bubble-cap, fractionating tower can bring about separations of two liquids whose boiling points are close together much more efficiently than can laboratory distillation equipment.

The visitor may gain a final impression of the scope and variety of laboratory apparatus by going through the stockroom of a chemical laboratory. An inventory of the shelves and bins will show hundreds of different types of equipment of many sizes. As many as 30 kinds of equipment will be found in the locker of a student in the first-year course, while in the research laboratory the number and variety of articles is very much greater.

Chemical Adviser, General Staff, Department of the Army.

CHEMICAL CRYSTALLOGRAPHY is concerned with the relations between the chemical constitution of crystallized substances and the structure of the crystals as revealed by their form and physical characters.

Consciousness of the specific relation between crystal structure and chemical constitution followed on the development of knowledge of crystal shape on the one hand and chemical composition on the other, toward the end of the 18th century, and culminated in the suggestion by René Just Haüy in 1800 that "to every specific substance of definite chemical composition capable of existing in the solid condition there appertains a crystalline form peculiar to and characteristic of that substance." By crystalline form we are to understand, not the precise shape of a crystal in all details, for the relative overall dimensions of a crystal and the relative areas of the faces are variable and depend on crystal growth conditions, but the shape of the unit of internal structure as indicated by the interfacial angles, which are constant for any one crystalline substance at a given temperature. Later studies have confirmed the soundness of this generalization, and contributed interesting amplifications.

Thus Eilhardt Mitscherlich in 1821 observed that substances which are closely related chemically often form crystals of very similar shape and only slightly different interfacial angles; such crystals are called isomorphous. We now know, as a result of X-ray diffraction studies, that the absolute dimensions of the structural units (unit cells) and the precise arrangements of the atoms are indeed very closely similar in such crystals. The closely related substances which form isomorphous crystals are often capable of crystallizing together in "mixed crystals" or "solid solutions" containing two or more substances, and Hermann Franz Moritz Kopp observed in 1840 that the tendency to form mixed crystals goes with similarity of molecular volume. This observation again foreshadows modern knowledge that molecules capable of forming mixed crystals are similar in absolute shape and size.

A still more subtle aspect of the subject was revealed by Louis Pasteur, who in 1848 found that tartaric acid forms two types of crystals related to each other as an object to its mirror image or a left to a right hand, and that a solution of one type rotates the plane of polarized

light to the left while a solution of the other gives a corresponding rotation to the right. This discovery was interpreted as indicating that two types of molecules of tartaric acid, each the mirror image of the other, existed and that the mirror-image relation (enantiomorphism) of the molecules is carried over into the crystal structures, which are regular arrangements of the molecules. Equal numbers of the left- and right-handed molecules can also crystallize together to give a third type of crystal (a racemic acid crystal) of quite different structure. Many other examples of the same phenomenon have since been discovered, and the enantiomorphism of the molecules concerned is now well substantiated by precise determinations of their configurations.

To Haüy's original generalization and its later amplifications some other remarks must be added to complete the broad overall view of the subject. In the first place, some substances which are not enantiomorphic are polymorphic—that is, they are capable of forming two or more types of crystals, which are different spatial arrangements of identical molecules or ions. For some substances, the different polymorphic forms can exist for indefinite periods of time at the same temperature, as with calcite and aragonite, the two mineral forms of calcium carbonate. For others, such as ammonium nitrate, which can form five different crystal structures, each is stable only over a limited temperature range, and if the temperature is progressively changed, each structure changes spontaneously at a sharply defined transition point into the next. It should also be remembered that for all crystals except those belonging to the cubic system the precise shape of the unit cell of any one crystal structure changes slightly with change of temperature. For tetragonal, hexagonal and orthorhombic crystals the non-equivalent edge-lengths of the unit cell have different coefficients of expansion, while for rhombohedral, monoclinic and triclinic crystals the nonorthogonal angles may also vary with temperature.

The unit cells of all the crystals of the many different substances which crystallize in the cubic system are of course all exactly the same shape: they are perfect cubes. Differentiation thus cannot be made on the basis of unit cell shape alone. Some measure of classification could be made on the basis of face development, since some crystals of cubic symmetry crystallize as cubes, others as octahedra, rhombic dodecahedra, or other more complex forms; but inasmuch as face development is often influenced by crystal growth conditions this basis leaves something to be desired. Thus, on a purely morphological basis the thesis of specificity seems to break down in the case of the cubic system, since many substances of very different chemical constitution crystallize in structures of cubic symmetry. However, other crystal properties, such as density and refractive index, do vary greatly from one substance to another, and, moreover, the absolute size of the cubic unit cell (at a given temperature), which can be determined by X-ray diffraction methods, is highly specific to each substance; and so the assertion of a highly specific relation between chemical constitution and crystal characteristics in the wider sense is valid.

Crystal Structure in Relation to Atomic and Molecular Geometry and Interatomic Forces.—By the use of X-ray diffraction methods, which were introduced in 1912 by Max

Laue and Sir William Henry and Sir William Lawrence Bragg, the atomic arrangements in very many crystals have been discovered. A survey of the results throws a good deal of light on the factors which determine the crystal structures of many different chemical substances. First among the concepts which help to build up a satisfying general picture is that of an atom as a spherical object of definite radius, of the order of 10^{-8} cm. Many chemical elements form simple crystal structures which may be regarded as close packings of spherical atoms: we may imagine spherical atoms drawn together by forces of mutual attraction and thus settling down in arrangements which appear to be determined by the requirements of economical packing rather than by the operation of specific directed bonds between neighboring atoms. There are actually two simple close-packed arrangements of spheres with the same packing density, the face-centered cubic structure and the hexagonal close-packed structure (Fig. 1), and about half the chemical elements (the rare gases and many metals) crystallize in one or other of these forms. A few crystallize in both. Different atoms have different radii, so that the unit cell size is characteristic of the element. Other metals crystallize in the less closely packed body-centered cubic arrangement, or in hexagonal, rhombohedral, or tetragonal arrangements which are not close-packed

Fig. 1.—Crystal structures of many elements. *Left*: Cubic close packing. *Right*: Hexagonal close packing.

arrangements of spheres. The existence of such arrangements may be interpreted either in terms of atomic force fields which affect not only the nearest neighbors but also more distant atoms, or in terms of nonspherical atoms or directed bonds. A few elements of less pronounced metallic character, gallium and uranium being examples, have much more complex structures for which no simple explanations have been suggested, but which may be interpreted in terms of specific directed bonds between neighboring atoms. These elements and their crystal structures are intermediate between metallic and nonmetallic

ones. Nonmetallic elements in general have more complex crystal structures than the metals, owing to the formation of specific directed bonds between atoms. This feature leads, for elements of low valency, to crystal structures containing localized atomic groupings which we call discrete molecules, while elements of high valency form continuous networks of directed (homopolar) bonds, the details of which are determined by bond angles. A molecule of a low-valency element is a tightly bound group of atoms, usually persisting in the liquid and gaseous states as well as in the solid, which has an effective size like that of an assemblage of partly merged spheres. The crystal structure is a packing of these assemblages, in which the distances between neighboring atoms (held by strong primary

bonds) in the same molecule are much smaller than those between the nearest atoms in neighboring molecules. Thus the halogens form diatomic molecules, each having the shape of a pair of partly merged spheres, while sulphur forms eight-atom rings (Fig. 2). The packing together of such molecules results in structures which are usually more complex than those of the majority of metals, in that two or more differently oriented molecules comprise the unit of pattern; nevertheless the more highly symmetrical systems (cubic to orthorhombic) are favored, in con-

Fig. 2.—Crystal structures of two nonmetallic elements. *Left*: Iodine. Two-atom molecules. *Right*: Sulphur. The molecules are puckered eight-atom rings, seen edgewise; one molecule is shaded.

formity with the high symmetry of the molecular structures. The full symmetries of the molecules, however, are not necessarily carried over into the symmetries of the crystal structures, which appear to depend largely on the requirements of economical packing of the nonspherical molecular shapes, though localized or directional forces between the molecules may also play a minor part.

The high valency of carbon leads to the formation, in diamond and graphite, of continuous networks of specific, highly directional homo-

Fig. 3.—Structure of diamond. (Skeletal representation: the sizes of the spheres have no significance, but merely serve to mark atomic centers.)

polar bonds, characterized in diamond by a regular tetrahedral arrangement of the four bonds of each atom, giving rise to a special cubic structure (Fig. 3), and in graphite by six-atom rings linked in honeycomb fashion to form plane sheets, which are stacked to form crystals of hexagonal symmetry.

The crystal structures of compounds are determined, in the first place, by the type of forces holding the different atoms together: the crystal structure types conform to the chemical classification of compounds based on the distinction between metallic and nonmetallic elements and their positions in the periodic table. The extreme

types are, firstly, crystals of alloys and inter-metallic compounds, which are closely related to those of the metallic elements; secondly, the compounds of nonmetallic elements, which are either arrangements of discrete molecules or continuous networks linked by directed bonds, just as in the crystals of nonmetallic elements themselves; and thirdly, the ionic compounds of metallic with nonmetallic elements, in which electrical forces between oppositely charged atoms or groups of atoms play an important part. But in addition to the extreme types, there is a range of intermediate types, some of which are of considerable crystallographic complexity.

True metals—the alkali and alkaline earth metals, and the transition metals like iron, together with copper, silver, and gold—form extensive ranges of solid solutions, with crystal structures like those of the constituent elements, if the atomic radii do not differ by more than about 15 per cent. If the radii are very different, compounds of definite composition are formed in which the relative numbers of atoms and the crystal structures depend on the packing capabilities of the different-sized atoms. The crystal structures are usually of high symmetry, cubic or hexagonal.

Compounds of alkali and alkaline earth metals with the less metallic elements, those of the B sub-groups of the periodic table, tend toward the ionic type which is considered later. But alloys of the transition metals with the less metallic elements form crystal structures which are determined by principles peculiar to the metallic state. The positively charged metal atoms are embedded in, and held together by, a sea of wandering valency electrons, and the crystal structures of these substances are apparently determined, as William Hume-Rothery (1899–) discovered, solely by the relative numbers of atoms and valency electrons; the relative numbers of the different atoms and the particular atoms by which the electrons are contributed appear to be of little importance. The chemical formulae of such phases are sometimes rather complex—for example, Cu_3Sn and Cu_5Zn —but the crystal structures are usually of high symmetry. With combinations of two B sub-group elements we return to compounds of simple, definite composition; the crystal structures are continuous networks of directed bonds. Throughout the various classes of intermetallic compounds, the crystal symmetry tends to be high.

A crystal of an ionic compound is an arrangement, electrically neutral as a whole, of positively and negatively charged atoms or groups of atoms, the structure of which is determined, as Viktor Goldschmidt realized, about 1926, by the relative numbers of positive and negative ions, by the demands of local satisfaction of electrical forces (positive ions being surrounded by negative ions and vice versa), and by the relative sizes and shapes of the ions. In the chemically simple ionic crystals composed of monatomic ions the influence of relative ionic size is particularly clear; for instance, many crystals of compounds of type RX (with equal numbers of positive and negative ions) are cubic, but the actual arrangement depends on the ratio of the radii of the two ions (see Fig. 4). For very low ratios, between about 0.2 and 0.4, packing considerations lead to structures like that of zinc sulphide, in which each ion is surrounded by four of opposite charge; from about 0.4 to 0.8, the sodium chloride arrange-

Fig. 4.—Structures of ionic crystals of type RX (containing equal numbers of monatomic ions). *Left:* Radius ratio 0.2–0.4 (zinc sulphide type). *Center:* Radius ratio 0.4–0.8 (sodium chloride type). *Right:* Radius ratio 0.8–1.0 (caesium chloride type).

ment is formed, in which each ion is surrounded by six of the opposite kind; and finally, from about 0.8 to 1.0, the caesium chloride structure in which the surround, or co-ordination, number is eight is formed. (The radius ratio limits quoted are not strictly observed: geometry is not the only factor, though it is the dominant one, for these substances.) Similar considerations determine many RX_2 structures, which again tend to be crystals of high symmetry.

In some ionic compounds, cadmium iodide being an example, the principle of local satisfaction of electrical forces is apparently abandoned, for the structure consists of composite layers, each consisting of a sandwich of a sheet of positive ions between two sheets of negative ions, within a layer each positive ion is surrounded by negative ions, but contacts between successive layers are contacts between sheets of negative ions. This phenomenon appears to be due to the strong polarization of the large negative ions—electrons are drawn in toward the positive metal ions in the center of the layer, leaving the outside of the layer less strongly charged, so that the forces between layers are more akin to those between discrete molecules. This type of crystal is thus intermediate between the ionic and molecular types.

In crystals containing polyatomic ions, in which atoms are held by directed bonds in precise configurations (for example, in carbonates and sulphates), packing considerations result in more complex and, on the whole, less symmetrical structures; orthorhombic and monoclinic crystals are more common than in any of the classes hitherto considered.

One of the most important classes of the more complex inorganic substances is the large group of silicate minerals, in which the binding is intermediate between the ionic and homopolar types. The subject of mineralogy has been largely rewritten as a result of the work of Sir W. L. Bragg and his school, who showed (1920–1930) that the basic motif of the silicate minerals is a group consisting of a silicon atom surrounded by four oxygen atoms. The linking of these groups in various ways to give silicon-oxygen networks held together by metallic ions results in a great variety of structures, which are often of considerable complexity and low symmetry (monoclinic or triclinic). Unlimited stringlike complexes give rise to minerals of the fibrous type like chrysotile, unlimited sheetlike complexes give micas and similar platy minerals with ready cleavage, while three-dimensional complexes form the structural basis of the feldspars and other rock-forming minerals.

Compounds of nonmetallic elements of low valency form discrete molecules, the packing of which depends partly on their shape but also on local electrical interactions, especially for those of strongly dipolar character. Compounds, like

silicon carbide, consisting of elements of high valency tend to form continuous networks linked by strong directed homopolar bonds, as in diamond.

The most important compounds of nonmetallic elements are the organic compounds, the combinations of carbon with elements of lower valency, chiefly hydrogen, nitrogen, and oxygen. These substances form discrete molecules, often of great complexity, which may be regarded as limited networks terminated by the atoms of lower valency. The crystal structures of hydrocarbons and others containing only weakly dipolar atomic groupings appear to be determined chiefly by the packing capabilities of the molecular shapes (see Fig. 5), but when strongly dipolar groups are present, such as hydroxyl, carboxyl, or amide groups, localized directional electrical attractions play an important part. The symmetries of crystals of organic compounds tend to be low—orthorhombic, monoclinic, or triclinic. Even highly symmetrical molecules very often do not form highly symmetrical crystals; for example, benzene, in spite of the full hexagonal symmetry of the molecules, forms orthorhombic

FIG. 5. —Structure of naphthalene crystals. A single molecule is shown on the right, with atomic centers and chemical bonds marked. In the crystal structure (left) the molecules are seen nearly edge-wise

crystals, and hexamethyl-benzene molecules, which are also hexagonal, form triclinic crystals. On the other hand, hexamethylene tetramine molecules, which have tetrahedral symmetry, form cubic crystals. The actual arrangement appears to depend on packing capabilities, which may or may not utilize the symmetries of the molecules themselves.

There is a rough reciprocal relation between molecular shape and crystal habit, for flat molecules tend to pile rapidly, giving needle crystals, while chain molecules pack in parallel fashion like sticks, giving rise to platy crystals. Very long chain molecules like the natural and synthetic polymers used for rubbers, plastics, and fibers do not usually form individual crystals containing whole molecules; they form aggregates in which only limited portions of the chain molecules form crystalline arrangements with their neighbors. But some of the very complex protein molecules coil up in a regular way to form compact molecules which are able to crystallize well. In electron microscope photographs by Ralph W. G. Wyckoff (1897–) of some of these crystals, the individual globular molecule can be clearly seen, arranged in just the manner already deduced from X-ray diffraction patterns of the crystals.

Applications of Crystallographic Methods to Chemical Problems.—Identification.—Crystallographic methods of identifying chemical substances are valuable for more than one reason: they are nondestructive, they require very small amounts of material, and, as compared with chemical methods, they identify, not merely atoms or functional groups of atoms in a compound, but the actual compound itself. Three different crystallographic methods are used. One is based on the measurement of interfacial angles, the second on measurements of refractive indices and other optical characteristics, and the third on the pattern of diffracted X-rays obtained when a monochromatic beam is passed through the specimen.

Attempts to use 19th century morphological methods for identification were not entirely successful, although much progress had been made. In the present century T. V. Barker (1881–1931) and his school have devised an effective systematic method based on a set of empirical rules for assigning indices to faces and the use of lists of key angles. The capabilities of the method are limited by the necessity of obtaining well-formed crystals large enough to be handled individually; and it is not valid for crystals of the cubic system. Nevertheless the Barker index of crystals offers a valuable method of identification.

For transparent crystals it is possible to measure under the microscope the principal refractive indices—up to 3 in number for the crystals of lowest symmetry—by methods based on immersion of the crystals in liquids of known refractive index. At the same time other optical characteristics may be observed. Identification is effected by reference to tables in which crystals are listed in order of the intermediate index of biaxial crystals (triclinic, monoclinic and orthorhombic), the index for the ordinary ray of uniaxial crystals (tetragonal, hexagonal, and rhombohedral), and the sole index of isotropic (cubic) crystals. Mineralogists have for long used related methods of identifying constituents in rock sections. The advantages of these methods are that they can be used for powders consisting of microscopic grains of quite irregular shape, and that they are applicable to mixtures of several constituents.

The most effective crystallographic method of identification is the X-ray diffraction method. The diffraction pattern of a crystal consists of a number of diffracted beams of different intensity, each at a definite angle; the pattern is of such complexity that it can be used as a fingerprint of the substance. The X-ray diffraction method is most frequently used for powders consisting of small, randomly oriented crystals, irradiated by a narrow beam of X-rays which need not be strictly monochromatic but must contain a strong component of sharply defined wave length. The pattern is recorded either on photographic film or on Geiger counter equipment. Identification is effected by reference to a card index published by the American Society for Testing Materials, in which the three strongest diffracted beams of each substance are arranged in order of the crystal plane spacings corresponding to their diffraction angles. This method, like the refractive index method, can be used for mixtures of several constituents, and has an even wider application, as it is suitable for crystals of all substances, even if they are of submicroscopic size. Approximate quantitative analyses of mixtures, including

mixtures of polymorphous forms of any one substance, and solid solutions can also be made by this method.

The X-ray powder method of identification is widely used for inorganic substances. Its application to organic substances, however, is less developed, owing to lack of data on the vast numbers of substances, and to the increased possibilities of similarity between powder diffraction patterns of closely related substances (such as large molecules differing only in the position of a single atom). Differentiation in such cases can be effected by single crystal X-ray diffraction patterns, which are sure to display some differences of unit cell dimensions and of relative intensities of the diffracted beams. In the use of this method of identification the work of John Desmond Bernal (1901–) and his school on the sterols is notable. The method is not direct and systematic, but rests on *ad hoc* comparisons with the patterns of known standard substances.

Determination of Molecular Weight.—The dimensions of the unit cell of a crystal may be measured accurately by X-ray diffraction methods. If the volume of the unit cell is multiplied by the measured density, the weight of the matter in the unit cell is obtained. Since the unit cell contains either one or some small number of molecules, the unit cell weight is equal either to the molecular weight or a small multiple of it. Consequently, if a rough idea of the molecular weight is known from other evidence, the precise value can be obtained from the X-ray data and the density. This method is particularly valuable in cases where the standard physicochemical methods fail.

Determination of Precise Stereochemical Details.—By detailed interpretation of X-ray diffraction patterns, it is usually possible, for crystals which are not too complex and molecules containing up to 20 or 30 atoms (excluding hydrogen atoms), to determine the precise positions of all the atoms in the unit cell, except perhaps hydrogens. This information gives the detailed stereochemistry, not only the general arrangement but also the precise interatomic distances and the angles between the bonds. The general conclusions on atomic sizes and arrangements have been mentioned earlier. It remains to point out that the conclusions have contributed much to the development of the theory of chemical bonding and the relations between interatomic distances and the type of bonding, the number of bonds formed by any one atom, and the angles between the bonds. In organic chemistry, the tetrahedral disposition of the four bonds of saturated carbon compounds suggested by Joseph Achille Le Bel and Jacobus Hendricus Van't Hoff in 1874 has been quantitatively confirmed, and with it the basis of the enantiomorphism of the tartaric acids and similar substances. Further than this, it has even been found possible to discover which of the two mirror-image configurations of molecules is found in each type of crystal; this historic completion of the edifice of stereochemistry begun by Pasteur was achieved in 1950 by Johannes Martin Bijvoet (1892–) working appropriately in the Van't Hoff laboratory in Utrecht. Among other complex problems of stereochemistry solved by X-ray crystallography, we may mention that the configurations of sucrose and other sugars and those of isomers of some of the cyclohexane derivatives have been discovered. The planar configurations of double-bonded groups and the

linear character of triple-bonded groups have also been established, together with the relation between bond length and bond order. Aromatic ring systems are found to be planar, and the precise lengths of the bonds in the various different situations in multi-ring systems are found by John Monteath Robertson (1900–) and his school to be in general agreement with the results of calculations based on the wave-mechanical theory of electronic bonding.

A great deal of information in intermolecular stereochemistry has also been accumulated as a result of measurements of distances between atoms in neighboring molecules. The effective external radii (Van der Waals radii) of different atoms in a variety of situations, and the relations between interatomic distances and the type of attractive forces, are now known. For example, it is now known that hydrogen bonding between acid, alcohol, and amide groups in neighboring molecules results in shortened interatomic distances.

Although for crystals of complex organic substances it is usually necessary to know the chemical constitution in order to solve the intricate puzzle of the crystal structure, it has sometimes been possible, notably in the case of the penicillin salts, to decide between alternative suggested chemical formulae by detailed crystal structure determination. Finally, the methods of X-ray crystallography are being applied to what is probably the greatest problem of chemical constitution and stereochemistry, that of the structure of the proteins. See CRYSTALLOGRAPHY—*Crystal Structure*.

CHEMICAL ENGINEERING. **Definition.**—With the widening of the work of the chemical engineer, attempts have been made to define chemical engineering in the broadest and most fundamental manner. For instance, chemical engineering has been defined as that branch of engineering having to do with chemical change on the manufacturing scale or with physical changes connected therewith. However, the following older and classical definition is certainly more explanatory: "Chemical engineering is that branch of engineering concerned with the development and application of manufacturing processes in which chemical or certain physical changes of materials are involved. These processes may usually be resolved into a coordinated series of unit physical operations and unit chemical processes. The work of the chemical engineer is concerned primarily with the design, construction, and operation of equipment and plants in which these unit operations and processes are applied. Chemistry, physics, and mathematics are the underlying sciences of chemical

engineering, and economics its guide in practice."¹

Origin.—In London in 1880 an attempt was made to found a society of chemical engineers. However, because of the small number interested, this society did not materialize. George L. Davis gave a series of lectures in 1887 in Manchester, England, which were expanded into his book *Handbook of Chemical Engineering*. While this presentation was largely qualitative, it did embody, in a formal presentation, the beginnings of our modern chemical engineering. Davis in this early work laid stress upon the importance to a practicing chemical engineer of a broad knowledge of chemistry, physics, and mechanics. He pointed out the necessity of acquaintance with materials of construction and corrosion, emphasizing the latter as one of the distinctive characteristics of the practice of chemical engineering.

Chemical engineering has grown out of chemistry and certain aspects of mechanical and metallurgical engineering during recent decades somewhat similarly to the way electrical engineering grew out of physics several generations ago. The rapid development of the chemical industry before, during and immediately following World War I brought so many new facts to the attention of the technical men engaged in this line of manufacture that the branch of engineering recognized now as chemical engineering came into a lusty growth. This took place rapidly in America and arose as a result of scientifically classifying the unitary aspects of many diverse and unlike procedures. Out of this classification arose as the first foundation of chemical engineering, the concept of the unit operations. This led to the intensive study of individual unit operations, such as filtration, centrifugation and many other of these physical aspects of the chemical industry. Much of the credit for the unit operations viewpoint should go to a group of chemical engineers associated with the Massachusetts Institute of Technology and led by William H. Walker and Arthur D. Little. Walker joined the faculty of the Massachusetts Institute of Technology in 1903 for the purpose of reconstructing the chemical engineering curriculum. It had been started in 1887. His work can best be described in the words of Warren K. Lewis:

"Walker inaugurated the instruction in the fundamental processes of chemical industry in these early years. (I² remember helping him in the development of his analysis of distillation in the fall of 1905 when I was an assistant in the laboratory under him.) The credit for recognizing the type of training needed by the men who were to solve the problems of chemical industry is clearly his. However, Walker and Little had worked together for many years and it was Little who, recognizing the character of the innovations of Walker, coined the phrase 'Unit Operations' (about 1914). Furthermore, to Little belongs the full credit for the suggestion of the School of Chemical Engineering Practice as an effective method for giving the student practical training in engineering work."

This unit operations method of handling the physical aspects of chemical engineering was

embodied in formal shape by three professors of this same institute namely, William H. Walker, Warren K. Lewis, and William H. McAdams in their book *Principles of Chemical Engineering*, published in 1923.

Later on, around 1930, the unit process concept, or the study of the unitary chemical aspects, came into the chemical engineering picture. This is still in its developmental stage and is being actively studied and defined.

Sphere.—The practice of chemical engineering lies in industrial application of chemical change or in the processing of chemicals. Particularly in the United States this has been so broadened and so extended that the industries wherein chemical engineering is practiced are often now called the "chemical process industries." The work in these industries includes the design, installation and supervision of plants for the manufacture of such products as acids, alkalis, salts, fuel gases, industrial gases, ceramics, cement, glass, fertilizers, sugars, starches, paper, rayons, solvents, explosives, war gases, paints, lacquers, leather, oils, soap, rubber, resins, plastics, intermediates, dyes, petroleum products and many miscellaneous chemicals and certain metals, such as aluminum, sodium, magnesium, calcium, tungsten and tantalum. These latter are shared with metallurgical engineering.

Divisions.—The two main divisions of chemical engineering are unit operations or physical changes and unit processes or chemical changes. The breaking down of chemical engineering into these more or less common units has been extraordinarily simplifying and has enabled much order and advancement to be applied to this rapidly growing branch of engineering. However, chemical engineering cannot be defined simply as a summation of the units of these two divisions. Judgment, experience, vision, humanity, and the ability to work with other men are as necessary for success in chemical engineering as in any other human endeavor.

The cutting across the diverse industries involving chemicals and chemical change by the unifying principles of the unit physical operations and the unit chemical processes emphasizes the similar aspects. This acted as a stimulus to further research towards a formulation of the general laws pertaining to unit operations and to unit processes. This quantitative formulation is still progressing but it is the very basis of chemical engineering.

The study and observation of the principles involved in the operations of evaporation, crystallization and filtration, for example, throughout the sugar industry, not only increased the usefulness of these unit operations in this sugar industry and others already using them, but enabled these same principles to be more intelligently and usefully applied to newer and developing industries. This is engineering progress.

Physical Changes or Unit Operations.—Unit operations are the older of the two main divisions of the units into which we customarily break down chemical engineering. More emphasis has been placed upon the study of these physical changes than the other or chemical changes largely because of the fact that the study of these unit operations had never been undertaken by the chemists in any serious way. On the other hand, the investigation and formulation of unit operations have long been the distinguishing characteristic of much of the research

¹ Newman, quoting Kirkpatrick, *Development of Chemical Engineering Education*, Supplement to *Transactions American Institute Chemical Engineers*, 34, No. 3a, p. 6, 25 July 1938; see also *ibid.*, 32, 568 (1936).

² Warren K. Lewis.

in chemical engineering. The chemical engineers interested in this phase have been very successful in the establishment of hypotheses and later on of laws pertaining to unit operations. The most recent book in this field is that written by Prof. G. G. Brown, *et al.* entitled simply *Unit Operations* (see *Bibliography*). Here Professor Brown has classified the various unit operations under four main headings of: (1) solids; (2) fluids; (3) separation by mass transfer; and (4) energy and mass transfer rates. In this book by Dr. Brown and in many of the other publications pertaining to unit operations, there are available formulations expressing the laws pertaining to these various physical changes. However, the best over-all summary of unit operations together with detailed literature references can be had from *Chemical Engineers' Handbook* edited by J. H. Perry (see *Bibliography*).

There are many ways to name the unit operations and to classify them. In the following table is listed the principal unit operation, arranged under the subheadings of energy transfer and mass transfer. However, some of the unit operations involve both energy transfer and mass transfer. In arranging this table the unit operation was placed under whichever one of these subheadings seemed to be the more important. In the table of the principal unit operations, an attempt has also been made to point out that many of these can be considered the reverse of another unit operation. This has been done by writing, for instance "heating vs. cooling."

PRINCIPAL UNIT OPERATIONS

Energy Transfer

(A) Mechanical energy transfer

1. Size reduction (crushing and grinding) vs. size enlargement

(B) Heat energy transfer

3. Heating vs. cooling
4. Evaporation vs. evaporative cooling

Mass Transfer

(A) Bulk mass transfer

5. Transportation of fluids (fluid flow)
6. Material handling (transportation or storage)
7. Classification or sedimentation of solids vs. fluidization
8. Flotation
9. Filtration (fluid flow through porous media)
10. Centrifugation
11. Mixing vs. separation (sedimentation)

(B) Molecular mass transfer

12. Distillation vs. absorption (liquid-liquid)
13. Extraction or leaching vs. crystallization
14. Adsorption
15. Gas diffusion
16. Drying

It has appeared to the writer and his associate, Prof. T. C. Doody of Purdue University, that the above classification is the simplest and best one available and is very superior to the classical method of simply naming: flow of fluids, filtration, heat transmission, evaporation, distillation, adsorption, absorption, extraction, crystallization, humidification, drying, size change, mechanical mixing, separation and transportation. As investigation proceeded, newer unit operations were added to this classical list as new physical aspects developed and were studied, for example, such as gas diffusion.

Chemical Changes or Unit Processes.—

Unit processes pertain to the various groups of chemical changes such as are carried on in our factories in a competitive and economical manner. This definition gives to unit processes a manifold aspect and includes: (1) the basic chemistry of the reaction; (2) the equipment in

which the reaction takes place; and (3) the conductance of the entire process with a sufficiently low cost as to be competitive. The following table gives examples of these unit processes:

PRINCIPAL UNIT PROCESSES

- | | |
|--|---|
| 1. Combustion | 17. Hydrogenation, dehydrogenation and hydrogenolysis |
| 2. Oxidation | 18. Alkylation |
| 3. Neutralization | 19. Friedel-Crafts |
| 4. Silicate formation | 20. Condensation |
| 5. Causticization | 21. Polymerization |
| 6. Electrolysis | 22. Diazotization and coupling |
| 7. Double decomposition | 23. Fermentation |
| 8. Calcination | 24. Pyrolysis or cracking |
| 9. Dehydration | 25. Aromatization |
| 10. Nitration | 26. Isomerization |
| 11. Esterification | 27. Acylation |
| 12. Reduction | 28. Hydroformylation (oxo) |
| 13. Ammonolysis | 29. Ion exchange |
| 14. Halogenation | |
| 15. Sulfonation | |
| 16. Hydrolysis and hydration (saponification, alkali fusion) | |

In applying these chemical changes industrially, the chemical engineer is particularly concerned with: (1) how far the chemical change will go or the chemical equilibrium; this is the basis of the chemical conversion and yield; (2) how fast the chemical change takes place or chemical kinetics; (3) the equipment for the chemical change; and (4) the cost of the process.

Chemical conversion refers to the per cent, generally expressed molecularly, of the main raw material converted into the principal finished product. Frequently these chemical reactions do not convert all of the initial raw materials into the products, some raw materials being recovered and used over again. Hence, there is a net consumption of the raw material or materials. The percentage of the net raw material converted into the product is the yield of the reaction.

The ethics of the chemical engineer should always lead him to render the best service to his organization and to society. This is reflected in the production of low cost goods so that more people can consume them. In order to do this, conversion and yields must be high. Therefore, for the most economic performance of a given industry, reactions and conditions must be chosen which aim at the obtaining of both high conversion and high yields. Thus wastes are avoided both in material, energy and labor.

A summary of the advantages of the unit process classification as applied to the chemical industry may be summarized as follows¹:

(1) The *unitary* or like aspects are accentuated by subdividing the various processes into their individual unit process characterized by the *basic chemical reaction*. Such things as similarity in energy change, corrosion, reaction time, catalysis, pressure, equilibrium and raw materials are emphasized.

(2) To an increasing extent, one finds in different chemical plants a *factory segregation* according to the unit process. A building or a part of the plant will be set apart to carry on nitration or hydrogenation, alkylation or pyrolysis or fermentation.

(3) The close relationship occasioned by factory segregation brings together like *equipment*. In the area of the plant devoted to hydrogenation, there will be much similarity in the equipment used for this unit process. This likewise will prevail for reductions or nitrations or many other of the unit processes.

(4) The segregation and the similarity in equipment lead more easily to the *multiple use* of equipment. Of course, the aim of the plant manager is to employ a given piece of equipment year in and year out for the making of the same chemical but frequently markets vary, and for this one piece of equipment can be used at one time for the halogenation of one chemical and later on for that of another. Indeed, in the advertisements of chemical

¹ Compare Shreve, R. Norris, *Chemical Process Industries*, Chap. 2 (see *Bibliography*).

journals, one sees chemical concerns advertising custom hydrogenations, for example.

(5) Above anything else, the classification and arrangement under the unit process concept enable the chemical engineer to design and plan on the basis of group performance. In this way basic principles pertaining to an entirely similar group of reactions are emphasized rather than the specific details of individual performance. These specific details enter more into a modification of the group conditions. Past knowledge with other members of a group help greatly in the handling of the manufacture of a new chemical within this same group.

(6) However, the outstanding characteristic of the unit process classification is that the emphasis in the chemical process industries is on the *chemical change*, that is, on the chemical reaction. In the large majority of manufacturing procedures in the chemical field, this is necessary because by the increase in the yields of even only a few per cent, there results usually a proportionally larger lowering of the cost than from other savings. This is because the cost of raw materials varies from 50 to 87 per cent of the manufacturing expense in the making of chemicals. Of course, similarly with such chemical savings should go the careful investigation of every unit operation involved in order to save heat or power or any other of the physical factors.

(7) There is no necessity to separate a unit process into *organic and inorganic phases* or even into the aliphatic and aromatic organic aspects. Indeed, it is more unifying not to make any such subdivision, since similar principles are connected with a unit process. This may be exemplified by the oxidation of carbon, hydrogen and naphthalene where the reaction of all are highly exothermic and the evolution of this heat must be carefully handled.

(8) With increasingly competitive conditions, the design of equipment for the arrangement of the various steps is given more and more emphasis by the chemical engineers. The unit process arrangement bringing together the analogous aspects of these factors, such as chemical reactions and equipment, enables the design chemical engineer to take advantage in a wide range of the manufacturing procedures, of any significant improvement in an individual reaction.

Catalysis.—A reaction may proceed to a very high yield at equilibrium but it may also take so much time to do this that the reaction would be a costly one in practice. This was true of the fixation of nitrogen from the air by reacting with hydrogen to form ammonia or of reduction of carbon monoxide with hydrogen to make methanol, until methods for increasing the speed of the reactions by the use of catalysts were discovered. Indeed, a very important aspect of the work of the chemical engineer is the development, design and operation of equipment for speeding up reactions through the application of catalysis.

Chemical Equilibrium and Chemical Kinetics.—These are both physico-chemical considerations. In many cases, the data are available so that for given reaction conditions the equilibrium and the speed can be expressed quantitatively and mathematically. This is a tremendous help to the chemical engineer in his endeavor to design plants for the manufacture of chemicals or to control chemical reactions under the most economical conditions.

Material Balances.—As materials are often the principal items of cost in chemical manufacturing, one of the chief functions of a chemical engineer in connection with these manufacturing processes, is to make a quantitative listing of all incoming raw materials and to balance these with all products and byproducts. This immediately discloses to him where wastes are occurring and acts as a stimulus to the more economic development of the procedure or of the industry being studied. Losses disclosed by such material balances may be both chemical and mechanical. To avoid chemical losses, it may be necessary to go back to the chemist in the laboratory for a further study of the fundamental chemical reactions concerned. To overcome mechanical losses there may be required a more careful design and a stricter application of the principles underlying

such unit operations as materials handling. Fig. 2 includes the very rough material requirements per ton of soda ash produced but it does not include a complete balance with nitrogen and calcium chloride wasted which should be included in any overall material balance.

Energy Balances.—In our chemical manufacturing operations energy may be consumed not only by the unit physical operations but also by the unit chemical processes. On the other hand, energy is evolved in the exothermic chemical reactions and frequently can be saved and used in the overall set-up. To secure an accurate calculation of all the energy changes concerned with a given industrial procedure, the chemical engineer works up a balance sheet listing quantitatively with their sources all the different types of energy required together with all the various kinds of energy concerned. While generally the overall picture requires that energy be supplied in the form of either fuel or electricity, there are cases where a factory has a surplus of energy generally from heats of reaction, and can dispose of it either in the form of power or of heat.

Flow Sheets.—In considering a given manufacturing process from the viewpoint of the original design or its operational control, it is fundamental in chemical engineering to break down the manufacturing steps to which the raw materials are subjected to furnish the salable product, into a coordinated sequence of these unit chemical processes and unit physical operations. This sequence is customarily illustrated in what are called flow sheets or flow charts. These are of varying complexity.

In Fig. 1 is depicted simplified or block type flow sheet such as is frequently employed by chemical engineers when they start taking a process from the research chemist in the laboratory through the pilot plant preparatory to the manufacturing establishment. As the details of the manufacturing procedure are worked out during the development, such flow sheets are elaborated and indeed frequently are changed into the diagrammatical flow chart as shown in Fig. 2. Here a diagram that simulates the different pieces of equipment is actually inserted in the sequence. In these various items of equipment, are carried out the unit chemical processes or unit physical operations as illustrated in the flow charts. In a pump, for example, the unit operation of *fluid flow* is industrialized. In the lime kiln of Fig. 2, the unit process of *calcination* is applied to the manufacturing sequence but this is also true of the unit operation of *heat transfer*.

At a later stage, the design chemical engineer may draw to scale each piece of equipment and cut these out of cardboard. Such cardboard replicas may then be juggled around to secure the best arrangements in the space of the building or of the plot chosen for the particular process. Quite frequently, many flow sheets will be worked out during the development of a process from the test tube to the actual manufacturing plant.

Pilot Plants.—The ideal, from an engineering viewpoint, would be to have available such data and formulas that a new establishment could be designed without a pilot plant. This may be true for a new factory for making a well known old product, but when a chemical engineer is engaged in the design and building of a chemical plant for an entirely new chemical or an entirely new process, the only safe procedure is to operate a

pilot plant as a most important steppingstone between the work of the chemist in the laboratory and the large manufacturing installation. The chemist in the laboratory can certainly secure quantitative conditions necessary for the obtaining of a good chemical yield but only in the pilot plant can the engineering aspects of the application of chemistry to industry be tested out effectively. The pilot plant frequently will be first an enlarged laboratory and then a small replica of the factory. Indeed, in certain large manufacturing operations, experience has shown that as many as five pilot plants should be successively constructed of increasing size. However, unless there are many radical aspects in a new process, one such pilot plant usually suffices.

The pilot plant should be built out of units comprising a small sized replica of what the design chemical engineer judges the large plant should be like. This pilot plant enables him to test out his judgment and to correct it if necessary. It also enables the chemical engineer to ascertain if he has chosen the right equipment to carry out the various unit physical operations and unit chemical processes the sequence of which represents the entire manufacturing procedure. Indeed, the pilot plant should be built in conjunction with the drawing of the later flow sheets and should represent the actual equipment which the flow sheet pictures on paper. In these pilot plants the same raw materials should be employed as are planned for the large manufacture, with equipment of the same composition so that corrosion can also be investigated effectively on the small scale and corrected prior to the construction of any large plant.

Equipment.—The chemical engineer deals with factory equipment. Much of his success will come from the proper selection and arrangement of this equipment in which the coordinated sequences of unit physical operations and unit chemical processes are commercialized. While much specialized equipment must be designed and tested in the pilot plant for chemical manufacturing, in most cases standard equipment is available in the shape of pipes, valves, pumps, filter presses, centrifuges, nitrators, sulfonators, and the like. This equipment is currently presented in the annual *Process Industries Catalog* and the *Chemical Engineers' Handbook* (see *Bibliography*.)

Process Instrumentation.—The chemical process industries are operated to an increasing extent every year on continuous procedures. Here the use not only of recording instruments but of *directional* instruments is a necessity to keep the procedure at the designed conditions. Such instruments are also a necessity for modern batch manufacture. These instruments save labor and produce more uniform products.

Economics.—As chemical engineers aim only to be concerned with procedures which are economically competitive, they must study the costs of the raw materials, the labor situations and the markets for the goods. Here the governmental statistics pertaining to the production of raw materials and consumption of products are often of fundamental guidance. A successful chemical engineer must also be a good business man.

Plant Location.—The plant should be located in that position where it will give the best service to the public and hence, as a corollary, where it should make the most profit for its owners.

However, plant location is not as simple as this because other factors enter therein such as adequate water, fuel, power, climate, labor supply and lack of legal restrictions. Likewise, in order to lower the general overhead of management, storage, distribution and sales, a new plant may be added to an already existing factory.

Work of the Chemical Engineer.—A chemical engineer is one who practices chemical engineering as already defined and elaborated. However, the chemical engineer is actually concerned with a wide variety of activities. These may be divided into the following main headings:

Research Development Design	Manufacture Sales Management	Teaching Consulting
-----------------------------------	------------------------------------	------------------------

The chemical engineer who goes into sales or management may not be practicing the strict fundamentals of his engineering, but this training is often the best foundation for these other aspects of chemical industry. In sales, not only goods but services are involved; also in sales are the principal contacts with the markets from which arise demands for new products. Thus chemical sales need men with chemical engineering training. In the management of chemical plants, the chemical engineer has frequently come up through the very factory involved and consequently understands it thoroughly. He must, of course, possess those other qualities of personality, education and understanding that will enable him to direct other men and their work. This all means that the chemical engineer should be broadly *educated* in social values, business procedures and personal ideals rather than merely *trained* in the tools of his profession.

The Chemical Engineer and Society.—Like all engineers, the chemical engineer is accustomed by training and practice impartially to evaluate facts. He is also in the habit of collecting together these facts and of recognizing when sufficient data are not available to draw a sound conclusion. An engineer is competent to set in motion those lines of investigation needed when the facts are required to place a sure foundation under any contemplated plan for action. In other words, an engineer acts upon demonstrated data, or he proceeds to acquire what is needed before acting.

In addition to dealing with these material aspects of this profession, he must work with men. He frequently must study a present situation and use his best judgment regarding what the future will bring forth. While these human and social values are harder to weigh justly and impersonally, yet the engineer should draw sounder conclusions on the average than one without this education.

All this lays the foundation for broader service than is embraced by the mere practice of his profession, important though this may be in supplying to society at large the technical products of the chemical industry. The managerial aspects of our companies, particularly of the larger ones, require that the incumbents possess the ability skillfully to evaluate equipment and men, as well as the service these men and equipment can render to society at large. Therefore, chemical engineering should be the group from which managers of our chemical plants are selected.

This same impartial evaluation of situations should also make engineering trained men important in the wider aspects of public service. All engineers should be encouraged to take a great

interest, and indeed to become active participants, in the affairs of their communities and of society at large. Perhaps, out of this will come, in time, social betterment plans based upon carefully collected facts and not upon the whims of pressure groups.

Registration of Chemical Engineers.—Practically all states require that chemical engineers, as well as other engineers who are in responsible charge of engineering work, be registered as professional engineers. The purpose of this registration is to protect the public welfare in the safeguarding of life, health and property by establishing, as defined by the registration laws of the various states, the minimum qualifications for persons engaged in engineering practice. This registration also protects the trained and experienced engineer from competition with inadequately educated men.

Professional Affiliations.—The American Institute of Chemical Engineers, founded in 1908, is the leading organization of chemical engineers. Its objects are to enhance the professional standing of members, and to enable them to render better service to themselves, their industry and the nation. There are four classes of membership: student, junior, associate, and active. Before advancement to active membership a member must have been in responsible charge of chemical engineering work for a varying period depending on his formal education (three years for a man with a Bachelor of Science degree in chemical engineering, and five years for one without formal training). The institute sets a high standard of ideals for the profession by virtue of its code of ethics. At semiannual meetings papers covering various phases of chemical engineering may be published monthly in *Chemical Engineering Progress*, together with other papers submitted directly. The institute also exerts a stimulating effect on instruction by accrediting only those schools of chemical engineering possessing adequate staffs and equipment. The office of the institute is in New York.

The American Chemical Society (q.v.) serves both chemists and chemical engineers. It publishes an outstanding list of useful journals containing papers both on chemical engineering and on the chemistry upon which chemical engineering is based. The principal periodicals are as follows: *Chemical Abstracts* (this contains abstracts of articles throughout the world both in pure chemistry and chemical engineering); *Industrial and Engineering Chemistry* (this is the outstanding periodical for publication of original research articles of permanent value in the field of chemical engineering); *Chemical and Engineering News* (this weekly magazine covers this technical field in its many phases). The society also publishes other magazines pertaining largely to the purely chemical aspects, namely, *Journal of the American Chemical Society*, and *Analytical Chemistry*.

The Engineers' Council for Professional Development is the functional agency of the major engineering societies of the country with its main object the enhancement of the engineer's services in the public interest.

Universities.—The schools of chemical engineering in the various universities and institutes of technology in the United States have taken a foremost position in the development of modern chemical engineering. The engineering divisions of chemical companies are likewise contributing

extremely important data upon which the future development of chemical engineering very largely depends.

Bibliography.—In addition to the publications of the professional societies, the following books and periodicals should be consulted: Davis, G. E., *Handbook of Chemical Engineering* (Manchester 1904); Badger, W. L., and McCabe, W. L., *Elements of Chemical Engineering* (New York 1936); Walker, W. H., Lewis, W. K., McAdams, W. H., and Gilliland, E. R., *Principles of Chemical Engineering* (New York 1937); McCormick, H., ed., *Application of Chemical Engineering* (New York 1945); R. Norris, *Chemical Process Industries* (New York 1945); Hougden, O. A., and Watson, K. M., *Chemical Process Principles* (New York 1947); Brown, G. G., and associates, *Unit Operations* (New York 1950); Ewell, R. H., ed., *Chemical Economics Handbook* (Stanford, Calif., 1950); Perry, J. H., ed., *Chemical Engineers' Handbook*, 3d ed. (New York 1950); Groggins, P. H., ed., *Unit Processes in Organic Synthesis* (New York 1952); Kirk, R. E., and Othmer, D. F., eds., *Encyclopedia of Chemical Technology* (New York 1952); *The Process Industries' Catalogue* (New York 1952); *Chemical and Metallurgical Engineering*, published monthly (New York), and many other periodicals in specialized fields. Also other books of the chemical engineering series published by McGraw-Hill Book Company, Inc.

R. NORRIS SHREVE,
Professor of Chemical Engineering, Purdue University.

CHEMICAL EXTINGUISHERS. The five most common types of first aid extinguishers contain (1) foam; (2) soda acid; (3) vapor liquid; (4) carbon dioxide; (5) dry powder. Chemical extinguishers are brought into action by being inverted, or pumped, or by being both inverted and pumped.

Foam extinguishers contain a solution of aluminum sulphate and bicarbonate of soda with a foam agent; while soda acid extinguishers are charged with a bicarbonate of soda solution and sulphuric acid. Both of these types require protection from freezing, and neither is used on fires in live electrical equipment. Nor is the soda acid extinguisher used on burning oil, gears, or paints.

The vapor liquid extinguisher contains carbon tetrachloride and other components. The carbon dioxide extinguisher, as its name implies, is charged with carbon dioxide; and the dry powder extinguisher uses bicarbonate of soda and other powders. All of these three types do not require protection from freezing.

CHEMICAL INDUSTRIES. Chemistry has such an intimate and important part in modern industry that it is very difficult to define a chemical industry. The best test is whether or not the finished product is made of the same substances as the original raw material. A glass bottle is composed of wholly different chemical compounds from the sand, soda, and other ingredients which came into the factory, whereas an office desk is made of the same wood which went into the sawmill, and the glue which unites its parts and the varnish which coats it were not changed in the furniture factory.

For census purposes all manufacturing industries fall into seven broad classifications, one of which is called *Chemical Process Industries*. Since 1939 the value of the chemical process industries' products has increased fourfold.

The metals industries involve sufficient chemical changes from the raw ore to the finished alloy so as to be discussed briefly as chemical industries, even though the census classifies them separately.

Thus this article will discuss those industries in which the science of chemistry is sufficiently used to justify their inclusion.

There is a widespread notion that the chemical industries of the United States really began in 1914, when war stopped importation of European supplies. This is entirely wrong. John Winthrop (1606-1676; q.v.) was manufacturing chemicals in Connecticut before 1640. By the mid-19th century the chemical industries of the United States began to grow and by 1914 had

are fairly low. Relatively large amounts of steam and electrical power are needed. Wage scales are high, but the cost of labor is low in comparison with the value of products. Nearly four fifths of all chemicals are consumed in the chemical process industries themselves, most of them finding their way into such goods as rubber, paper, plastics, leather, and motor fuels.

attained considerable size and importance. They were confined largely to heavy chemicals and to those industries which are more or less common to all countries. Potash was a German monopoly. Synthetic ammonia was then a relatively small European industry. Synthetic dyes and synthetic drugs required an enormous amount of research for which the United States was not then prepared.

Chemical industries are characterized by great economic flexibility. Several different raw materials are often available for the same product. Conditions alter yields of the major product and determine the number and character of byproducts. For example, the demands for aviation fuels were so great during World War II that such industrial fuels as refinery gases and high-boiling distillates were made into gasoline. Since 1945 the highly unstable condition of the coal industry has led to a large increase in the production of fuel oil.

Chemical industries depend for their profitable operation on continuous and large-scale production. High hazards in manufacture and transportation require expensive precautions, but the numbers of serious accidents and property losses

Research particularly characterizes the chemical process industries, causing rapid changes and making many products and processes obsolete. The cost of preliminary research and development may well equal the cost of erecting the final manufacturing plant. The most striking results of research are the great increases in production and in quality of products with corresponding lowering of costs. In 1910 an automobile tire cost \$50 and might last 5,000 miles. The same type of tire now costs one third as much, has four times the mileage, and is made in many times the quantity.

The members of the chemical profession may be broadly divided into two classes: chemists and chemical engineers. The chemist is primarily concerned with laboratory work of some sort, while the chemical engineer designs and operates the mechanical equipment in which a product is made. Chemical training is required for all the important functions of a chemical industry, including research, production, technical service, public relations, patents, and sales. Two thirds of the 70,000 chemists in the United States are in some type of industry, mainly in the chemical process industries, and more than three fourths

of the 25,000 chemical engineers are similarly employed. Both are relatively young professions, the median age of chemists being about 33 and that of chemical engineers slightly under 30. Research, development, production, operation, maintenance, analysis and testing, process control, management, and administration account for most members of the chemical profession in industry. Not more than 10 per cent are engaged in teaching.

A process begins with fundamental research on physical properties, reactions, methods of analysis, materials of construction, raw materials, and uses. If successful in the laboratory, the process must be tested with larger quantities. Finally a plant is designed and the product is made in large quantities in continuous operations. Chemists, chemical engineers, mechanical engineers, and technical salesmen all have a share in bringing a process to successful operation.

To the chemist any chemical manufacturing operation must be divided into a series of unit chemical processes, or types of chemical reactions common to each process. Oxidation is a unit process employed in making both sulphuric acid from sulphur and nitric acid from ammonia. The same unit process may result in a dye intermediate, a pharmaceutical, or a vulcanization accelerator, depending on the substances used. This concept of unit processes greatly simplifies chemical industries.

The first consideration in equipment is materials of construction. The larger part of all chemical operations employs iron or steel equipment, even sulphuric and nitric acids being handled in iron vessels. Concentrated oxidizing acids render the iron passive and immune to attack. The cast iron in chemical equipment is a special alloy with less carbon, more silicon, and significant amounts of nickel, copper, and other metals. Iron containing 15 per cent silicon resists most acids. Special alloys of iron and chromium, some containing nickel, resist corrosion at high temperatures and pressures. Copper, lead, nickel, aluminum, and chromium are important metals in chemical equipment. Some processes require equipment lined with glass or with acid-proof brick or made of chemical stoneware. Other construction materials are carbon, wood, cloth, plastics, and rubber.

Chemical engineers view chemical manufacturing as a series of unit chemical engineering operations. These include the handling or flow of materials, the flow of heat, crushing, grinding, mixing, screening, filtering, evaporating, distilling, drying, and a few other operations of major importance. A still larger number of minor unit operations complete the field with which chemical engineers are concerned. Much special equipment for unit chemical processes has been designed, but most chemical manufacturing uses standard types of equipment for the common unit operations.

In the field of unit operations the pressure of war resulted in several new techniques which have been retained in the postwar period. In order to separate the isotopes of uranium the principles of gaseous diffusion through fine orifices were applied for the first time on a large scale, and this unit operation may become very useful in separating all sorts of gases of different densities. Porous membranes, the openings of which are submicroscopic, are used. A large number of such barriers separate the equipment into a

series of chambers. A part of the contents of a chamber diffuses forward into the next chamber, while the remainder is returned to pass again through the rear barrier. By sufficient repetition ultimate separation is effected. Where there is a great difference between densities, separation is relatively rapid and very few stages are required. The separation of the hexafluorides of uranium with molecular weights of 349 and 352 represented the ultimate in difficulty of separation and required millions of passages.

Induction electrical heating is applied in industries as varied as in the destruction of molds and enzymes in bread and fruits, the curing of synthetic resins in laminated products, the vulcanization of rubber, and the heat treatment of alloys.

Vacuum distillation under greatly reduced pressure has made possible separations of heat-sensitive substances, such as glycerides and vitamins, and similar low pressures have permitted the conversion of frozen fruit juices, blood plasma, and penicillin solutions to water-free solids without decomposition.

The technique of conveying finely divided solids in gases, after the solids had been brought to any desired temperature, was developed in the petroleum industry, but is being applied in other industries both to bring catalysts into contact with reacting gases and to control gaseous temperatures during reactions. See also *CHEMICAL ENGINEERING*.

There is no attempt in the following discussions of the leading chemical industries to make rigid classification according to any system.

Sulphur and Sulphur Products.—Some elemental sulphur is employed directly in fertilizers, insecticides, and explosives, and in the compounding of rubber, but more than four fifths of it is burned with air to sulphur dioxide, which in turn is very largely converted into sulphuric acid. Three fourths of the world's supply of sulphur comes from the Texas and Louisiana coasts on the Gulf of Mexico. It is found in limestone deposits above some of the salt domes of this region. The sulphur is melted by water heaters under pressure and is pumped to the surface by compressed air. This process was developed by Herman Frasch in 1902. The production of sulphur from these underground deposits amount in normal years to between 4 and 5 million tons.

Sulphur dioxide is made by burning sulphur and such sulphides as those of iron, copper, and zinc in air. Unless their location compels avoidance of damage to vegetation, smelters discard several times as much sulphur dioxide as the convert into sulphuric acid.

Liquid sulphur dioxide is a valuable refrigerant, and lamp oils and automobile lubricants are refined by extraction with it. Some chemicals such as hydrosulphites are made from sulphur dioxide. About one fourth of the total production is in the "cooking acid" of the paper pulp industry.

Sulphuric acid is made from sulphur dioxide by two methods: the *contact* and the *lead chamber* (or *nitration*) processes. It is very easy to oxidize sulphur to sulphur dioxide, but it is more difficult to attain the higher degree of oxidation.

In the contact process the gases from sulphur or pyrite burners, composed of 7 to 10 per cent sulphur dioxide, 11 to 14 per cent oxygen, and 76 to 82 per cent nitrogen, are carefully purified and passed over a catalyst to induce the reaction: $2\text{SO}_2 + \text{O}_2 = 2\text{SO}_3$. The catalysts now in use

eral use are finely divided platinum, spread on some inert material, and complex vanadium compounds. The gaseous mixture is cooled and passed through towers packed with clay shapes, over which 98 per cent sulphuric acid is flowing. The sulphur trioxide combines with the water in the absorbing acid to form sulphuric acid: $\text{H}_2\text{O} + \text{SO}_3 = \text{H}_2\text{SO}_4$.

The older lead chamber or nitration process still makes a significant amount of the sulphuric acid in the United States. It depends on causing sulphur dioxide, water, and oxygen to combine in the presence of a mixture of nitric oxide and nitrogen dioxide, which is commonly given the formula N_2O_3 . The complex substance so formed is decomposed by water into sulphuric acid and the oxides of nitrogen. These oxides are used again and again with some unavoidable losses. The process is performed in a series of towers and large lead rooms called chambers, which are supplemented by tanks, coolers, fans, and pumps. The product of the chambers is 60 per cent sulphuric acid, which is concentrated by hot burner gases to 80 per cent material. The waste gases from the chambers are scrubbed with strong sulphuric acid to recover the nitrogen oxides, which are returned to the process.

Sulphuric acid, like many other commercial liquid products, is described in terms of its specific gravity in the Baumé (Bé.) scale. Common varieties are 50° Bé. (1.53) or 62 per cent; 60° Bé. (1.71) or 77.7 per cent; and 66° Bé. (1.84) or 93.2 per cent. Oleum refers to solutions of sulphur trioxide in sulphuric acid. The larger part of all sulphuric acid is made from sulphur, most of the remainder from pyrites, and only a small fraction from byproduct sulphur dioxide.

More than half of all sulphuric acid is consumed in the manufacture of fertilizers and chemicals. The refining of petroleum, the recovery of coal byproducts, removal of mill scale from iron and steel, nonferrous metallurgy, paints and pigments, rayon, cellulose film, and explosives consume most of the remainder. Sulphuric acid is used in greater quantities than any other chemical. Its sales offer an excellent index of business conditions. The production of sulphuric acid in terms of 100 per cent material is of the order of 10 million tons per year. Until World War II all production data for sulphuric acid were given in terms of 50° Bé. acid (62.2 per cent) rather than in 100 per cent, which since has been the practice.

Ammonia and Nitric Acid.—Nearly four fifths of air is nitrogen, yet until the 20th century the world depended for nitrogen compounds on certain deposits in the uplands of Chile and on the fraction of one per cent of combined nitrogen recovered from coal gas. Man's continued existence depends on the fixed nitrogen derived from meat, milk, and plant seeds. Agriculture removes fixed nitrogen from soil more rapidly than soil bacteria can replace it from the air. Probably 85 per cent of all nitrogen compounds in peacetime are applied to the soil in mixed fertilizers.

The larger part of all industrial nitrogen compounds may be regarded as derived from the nitrogen of the air. Ammonia from coal carbonization is limited by the demands of the steel industry for blast furnace coke. Chilean nitrate accounts for only a small fraction.

The reaction, $\text{N}_2 + 3 \text{H}_2 = 2 \text{NH}_3$, appears simple enough, but yields only the merest trace

of ammonia in ordinary laboratory apparatus. Because the volume is reduced by one half when ammonia is formed, high pressures increase yields greatly. The catalyst is a spongy and active iron mass containing small amounts of aluminum and potassium. The best temperature is 500°C. Speed and yields are balanced against each other so that the largest possible quantity of ammonia is made in a given time. Yields per pass vary from 10 to 50 per cent depending on the pressure. Nickel and chromium alloys of iron are required. Pressures vary from 1,500 to 15,000 pounds per square inch.

Nitrogen is generally separated from oxygen by burning out the oxygen with carbon or hydrogen and absorbing or condensing the products, but some is distilled from liquid air. Hydrogen sources include electrolytic hydrogen, coke oven gas, natural gas, and water gas, which last equals in amount all other sources.

The larger part of ammonia is made into ammonium salts such as the sulphate. Liquid ammonia is a refrigerant and also a widely used alkaline material in the chemical industry.

Considerable quantities of ammonia are made into nitric acid. Ammonia and air are passed over red-hot platinum gauze, forming nitric oxide, NO, and water. The nitric oxide is cooled, oxidized to NO_2 , and with water formed into nitric acid, $3 \text{NO}_2 + \text{H}_2\text{O} = 2 \text{HNO}_3 + \text{NO}$. The nitric oxide is repeatedly oxidized and absorbed under pressure in nickel-chromium alloy towers. The 40 per cent water is removed with sulphuric acid, nitric acid distilling from the heated mixture.

Formerly most nitric acid was made by mixing Chilean sodium nitrate with sulphuric acid and distilling the nitric acid. Economic conditions have so changed that some sodium nitrate now results from the action of nitric acid on soda ash.

More than two thirds of all nitric acid goes into explosives, while the dye, lacquer, and plastics industries consume most of the remainder.

Nitrogen also is fixed in considerable quantities at a high temperature by calcium carbide. The reaction is $\text{CaC}_2 + \text{N}_2 = \text{CaNCN} + \text{C}$. The major product, calcium cyanamide, is mainly an ingredient of commercial fertilizers, but many important nitrogen compounds are made from it.

Fixed nitrogen production in the United States is of the order of 1.5 million tons, the larger part of which is utilized in mixed fertilizers or is applied directly as ammonia.

Alkalies.—Caustic soda and soda ash are the most important alkalies. Caustic soda (sodium hydroxide) is a byproduct in the manufacture of chlorine from salt. About three fourths of the commercial supply of caustic soda comes from this source. The remainder is made by treating a solution of sodium carbonate with a suspension of slaked lime: $\text{Na}_2\text{CO}_3 + \text{Ca}(\text{OH})_2 = \text{CaCO}_3 + 2 \text{NaOH}$. The calcium carbonate is washed free from caustic, reburned to quicklime, and slaked for re-use.

The chief consumers of caustic soda are the rayon, film, soap, petroleum, paper, and chemical industries. Production of this chemical is between 2.2 and 2.3 million tons per year.

Although some decahydrate, $\text{Na}_2\text{CO}_3 \cdot 10 \text{H}_2\text{O}$, is sold, most sodium carbonate appears on the market in the dry form as soda ash. It is made almost entirely by the Solvay process from sodium chloride. Brine is saturated with ammonia and treated with carbon dioxide gas. Ammonium

chloride remains in solution, while sodium bicarbonate, NaHCO_3 , is removed and converted to the carbonate by heat. Ammonia is recovered by slaked lime with very little loss. Small quantities of sodium carbonate are refined from the natural deposits of the Southwestern states.

Soda ash production reached a peak of 4.8 million tons in 1947. Its chief uses are in the manufacture of chemicals, particularly caustic soda, and in the glass industry. It is also important in the soap, paper, and nonferrous metal industries.

Chlorine and Hydrochloric Acid.—Chlorine is made from concentrated salt solutions by the passage of an electric current. Commercial cells, except those employing mercury cathodes, allow 40 per cent or more of the salt to pass through unchanged; a steady flow of brine and diaphragms of asbestos at the cathodes prevent backward diffusion of the caustic soda and reaction with chlorine at the anodes. Cathodes are perforated iron sheets and anodes are usually made of carbon. The two byproducts of chlorine cells are caustic soda and hydrogen.

At one time most chlorine was converted by lime into a crude calcium hypochlorite called bleaching powder. Modern bleaching powders contain both the double chloride-hypochlorite and the hypochlorite, $\text{Ca}(\text{OCl})_2$. Most chlorine is compressed and cooled to a liquid which is transported in cylinders and tank cars. Over 90 per cent of all chlorine is used in the making of chemicals and in bleaching paper and textiles. The remainder is mainly employed in disinfecting sewage effluents and public water supplies.

Some hydrogen chloride is a byproduct of the chlorination of hydrocarbons and some is made by burning hydrogen in chlorine, but most of it is made directly from salt and sulphuric acid. The gas is extremely soluble in water, its solutions being called hydrochloric or muriatic acid. Commercial hydrochloric acid is usually the 20°Bé. grade containing 31.5 per cent by weight of hydrogen chloride.

Chlorine production has continued to increase since the end of the war, amounting in 1949 to over 1.7 million tons. In terms of 18°Bé. acid containing 28 per cent hydrogen chloride dissolved in water, almost 1.6 million tons of hydrochloric acid were produced in 1949.

Bromine, Iodine, and Fluorine.—For many years the chief source of bromine in the United States was brine wells in Michigan. Increased demands for this substance led to the development of a process for extraction from sea water. Iodine is largely imported from Chile, where it is a byproduct in the refining of sodium nitrate from natural deposits, but considerable quantities are being made from oil well brines in California. Both substances are used primarily in the production of chemicals. Since 1940 fluorine, no longer a laboratory curiosity, has been produced in considerable quantities by the electrolysis of anhydrous sodium fluoride and sodium hydrogen fluoride. Although extremely reactive and corrosive, it enters into the manufacture of several organic derivatives including refrigerants and plastics. Hydrogen fluoride, once employed mainly to etch glass, is a common catalyst in the synthesis of high-grade gasoline.

Lime and Gypsum.—Vast quantities of limestone are used in making quicklime and portland cement and as a flux in the metallurgical industries. Heat decomposes limestone into quicklime

or calcium oxide and carbon dioxide. This is done in either stationary vertical or horizontal rotating kilns. Water converts the oxide to hydroxide or slaked lime, a valuable alkaline material about equally distributed among the chemical, agricultural, and building industries.

Gypsum is dihydrate of calcium sulphate. Careful heating removes three fourths of the water, leaving the hemihydrate, $(\text{CaSO}_4)_{\frac{1}{2}} \cdot \text{H}_2\text{O}$ (or plaster of paris), the main component of many wall plasters. Plaster of paris sets by absorbing water to form the dihydrate. Gypsum and slaked lime divide the plaster market, while gypsum wallboard is an important construction material.

Miscellaneous Heavy Chemicals.—Other important sodium salts include: sodium sulphate for the glass and paper industries; sodium sulphide, made from sodium sulphate for the dye industry; sodium silicate for adhesives and cleansers; the sodium phosphates in water treatment and with soaps; and sodium borate for the glass industry. Magnesium, zinc, copper, aluminum salts, and many other compounds have important places in the chemical industries.

Industrial Water Treatment.—Water supplies for industrial use and particularly for raising steam often require some type of chemical treatment. Suspended matter is removed by adding iron and aluminum salts with sufficient lime to make the water alkaline and to ensure a floc to aid in filtering. Calcium and magnesium salts have been removed or greatly reduced in concentration by the old and still quite common process of treatment with soda ash and lime in proper amounts, preferably with heating the water. The next development in industrial water treatment was to pass hard water through a bed of zeolite, a sodium aluminum silicate. Sodium was exchanged for calcium and magnesium with practically complete removal of these ions but with little reduction in dissolved solids. The filter bed was readily regenerated by soaking it in a strong sodium chloride solution. A series of organic resins have been developed, some of which will replace calcium and magnesium ions by hydrogen ions and others, containing amino groups will remove the entire acid molecule, thus taking out the acid radicals, such as chloride and sulphate, and leaving the water almost free from all dissolved substances. These base- and acid-exchange resins are regenerated readily by acids and alkalis respectively. This method of ion exchange and removal is applied both to laboratory research and commercial production in several chemical fields.

Considerable progress in water conditioning has been made by employing small quantities of sodium hexametaphosphate to prevent formation of scale in condensers and by adding larger amounts of the same substance to avoid formation of insoluble metal soaps in hard water in laundering and to suppress concentration of calcium ions in steam boilers to a point where calcium sulphate scale will not form.

Paint Pigments.—The most widely used insoluble solids composing about half the volume of paints are lead, zinc, barium, and titanium compounds. White lead is a basic carbonate; litharge and red lead are oxides of lead. Lithopone is a mixture of barium sulphate and zinc sulphide. Zinc oxide, a paint pigment, is extensively compounded with rubber in the tire industry. Colored pigments may be true chemical compounds or dyes absorbed on inert substances.

Fertilizers.—The most important nitrogen product in the fertilizer field is ammonium sulphate. Other nitrogen compounds in this industry are ammonium nitrate, phosphate and chloride, urea, calcium cyanamide, sodium nitrate, and calcium nitrate.

For many years Germany, and later Germany and France, had a world monopoly of the potash market, but in the period immediately preceding World War II the United States produced from California brines and New Mexico deposits at least half of the potassium compounds needed for agriculture. Only limited amounts of potash are imported into the United States, where production is between 1.3 and 1.4 million tons in terms of K_2O , most of which is sold to the agricultural industry.

Phosphates are used in larger amounts than any other type of plant food in mixed fertilizers. The raw material is a complex phosphate fluoride of calcium called phosphate rock. Treatment with acid is necessary in order to form substances that can be assimilated by plants. The product of mixing ground phosphate rock with $50^\circ B\acute{e}$. sulphuric acid is superphosphate. It contains beside silica and calcium sulphate mainly monocalcium phosphate, $Ca(H_2PO_4)_2$, and dicalcium phosphate, $Ca(HPO_4)_2$. Smaller amounts of a product with much higher phosphorus content, known as triple superphosphate, are made by treating phosphate rock with phosphoric acid. This acid may be made from phosphate rock by employing sufficient sulphuric acid, filtering, and evaporating, but some is made by burning phosphorus. The United States has vast reserves of phosphates, to which new processes involving flotation methods have added greatly by making lower-grade materials available.

Acidity of superphosphates may be reduced and valuable plant foods may be added by ammonia liquor or a solution containing water, ammonia, and urea.

In some years as high as 18 million tons of fertilizer materials have been sold in the United States. The plant food in mixed fertilizers in terms of nitrogen, N, phosphoric acid, P_2O_5 , and potash, K_2O , is about one eighth of the weight of the material as it is applied to the soil. A part of the remainder consists of necessary carriers, such as sulphate, chloride, and calcium, but large quantities of inert material are included to facilitate distribution. But some plant foods, such as ammonia, are applied in relatively pure form.

Glass.—Any hard, noncrystalline product of fusion is technically a glass. Commercial glasses have no true melting point, but pass from hard solids through a waxy consistency to a freely flowing liquid. Fabrication of glass is achieved so rapidly that crystallization is avoided. Glass must also have smoothness, hardness, resistance to solution and chemical action, and for most purposes either transparency or translucence. Low coefficients of expansion are necessary in laboratory and ovenware subjected to sudden heat changes.

Silica, SiO_2 , is the main acid oxide of commercial glasses, while calcium oxide and sodium oxide are the basic oxides. The chief sources of sodium oxide are soda ash and sodium sulphate (salt cake). Sodium sulphate is reduced by carbon to sodium sulphite in order that combination with silica can take place. Litharge and red lead impart high brilliancy to cut glass. Other substances in colorless glass are magnesia,

potash, zinc oxide, alumina, and boron compounds. Such materials as fluorspar, cryolite, tin oxide, and calcium phosphate remain in colloidal suspension and render glass opaque. Etching is accomplished by the action of hydrofluoric acid; designs are also ground on glass surfaces.

Colored glass is made by colored compounds of cobalt, iron, and chromium, and colloidal size particles of selenium, carbon, copper, and gold. Undesirable colors from impurities may be corrected by other colors.

A type of glass which breaks into rounded fragments rather than sharp slivers is made by special annealing, so that there is tension within and compression at the surface. Most safety glass, however, is made of two or more layers of ordinary glass cemented together by one or more layers of a transparent and colorless synthetic plastic, preferably one which does not become brittle when cold. Vinyl resins meet this requirement. Inclusion of tiny crystals of certain organic compounds in the plastic sheet and drawing the material to cause uniform arrangement of the crystals is the principle of a polarizing sandwich glass for goggles, car lenses, and windshields.

Other important developments in the glass industry include foam and fiber glasses and organic silicon compounds known as silicones.

Cellular glass is extremely light and is used in floats and as a heat-insulating material. Loose glass fibers function in filters, in distilling columns, in life preservers as a substitute for kapok, in cold-resisting clothing, and as heat insulation. Woven into cord and fabric, glass fibers serve as reinforcers of rubber and plastics in bandages which replace plaster casts, in electrical insulation, and in body armor which is efficient against shrapnel. Organic silicones as plastics, reinforced by glass cloth, have remarkable mechanical and electrical properties which greatly reduce the weight of motors and dynamos. Silicones vary from viscous fluids functioning as lubricants to rubberlike materials for heat-resisting gaskets and are also ingredients of heat-resisting paints and varnishes.

Laboratory and ovenware are borosilicate glasses with very low coefficients of expansion. A resistant glass is made from a melt which, after cooling and shaping, separates into two kinds of particles, one of which is dissolved in acids and the other is heat-treated until it has softened into a homogeneous state. Although there is shrinkage of about one third, the article retains its shape.

Small batches of glass are melted in open or covered porcelain pots, but most glass is made in large furnaces called tanks. Gas and oil are the common fuels. The ingredients, along with coarsely ground glass from rejected or broken articles (cullet), are fed intermittently at one end of the tank. By the time that chemical action is complete and the gases so produced have escaped, the molten glass flows through an opening in a wall across the tank, so that scum is stopped and clear glass collects at the working end of the furnace.

Glass articles are formed by a variety of drawing, blowing, pressing, or molding operations, most of which are performed by automatic and continuous machinery. The finished articles are reheated to relieve strains and are cooled gradually, a process called annealing.

Closely related to glass are fused coatings on

metals known as vitreous enamels. A powdered glass is mixed with clay and other pigments and either is applied dry to hot metal or is sprayed in suspension on cold metal, followed by heating in a furnace.

Nonsilicate glasses are of two types. Some lenses, said to have remarkable light-bending properties, are made from compounds of tantalum, tungsten, and lanthanum. Where resistance to hydrofluoric acid is necessary and transparent plastics are not suitable, a glass composed mainly of phosphoric pentoxide and small amounts of metallic oxides is said to have all the desirable properties of silicate glass.

Fused silica, although expensive and hard to fabricate, has many desirable properties. It does not soften at a point at which all commercial glasses will flow; it has an extremely low expansion coefficient; it resists the action of many corrosive chemicals. The usual procedure for fused silica is to imbue a resistor in a pile of sand until there is sufficient melting to permit formation of a sort of tube which is worked into shape by the usual operations. Occlusion of small gas bubbles causes opacity. Clear fused silica is made in an electric furnace from which gases may be almost wholly exhausted. Remaining bubbles collapse when pressure is restored. See also FIBERGLAS; GLASS, NON-REFLECTING; GLASS, VARIETIES OF; GLASSMAKING.

Clay Products.—Clays are mainly hydrated aluminum silicates with minor amounts of iron, magnesium, calcium, sodium, and titanium compounds. Nonplastic material, including flint, feldspar, and ground burnt clay, is necessary to permit proper shaping, drying, and firing. Refining is accomplished by grinding, flotation, removal of grit, coagulating, screening, and drying.

The clay is mixed with nonplastic materials, preferably with removal of air, and for some kinds of products is stored damp for several months. This permits combination of water and development of substances by bacterial action to improve plasticity. Clay articles are formed either by hand or by casting, pressing, or molding, and are very carefully dried. This involves some shrinkage, for which allowance must be made in shaping. The next step is firing in intermittent or continuous kilns. Complex chemical changes take place during this operation. Water is removed from hydrates; either oxidation or reduction, depending on kiln conditions, occurs; some silicates dissociate and others form; some products crystallize, but others fuse and unite the solid grains. Clay products include brick, tile, terra cotta, pottery, stoneware, chemical stoneware, porcelain, and refractories.

Portland Cement.—The following definition of portland cement is generally accepted by industry. "Portland cement is a finely pulverized material consisting of certain definite compounds of lime, alumina, and silica, which when mixed with water has the property of combining slowly with water to form a hard, solid mass."

Portland cement is made from two types of materials. The chief component of one is calcium carbonate and that of the other is aluminum silicate containing some iron. Limestone, marl, chalk, and calcium carbonate wastes furnish calcium carbonate, while silicates come from clays, shale, or blast furnace slag.

The raw materials are crushed, ground, and finely pulverized. If ground in water, the thin slurry is often thickened or filtered. Flotation

methods permit the rejection of excessive alumina and silica and the utilization of lower-grade rock.

Modern cement kilns are refractory-lined steel cylinders, sometimes over 400 feet long and from 6 to 12 feet in diameter, slightly inclined from the horizontal, and driven slowly by a girth gear. Kilns are equipped with dust chambers, waste heat boilers, exhaust fans, and stacks. Fuels are oil, gas, or powdered coal.

As the raw materials move down the kiln, water is driven out, calcium carbonate decomposes, and exothermic reactions between the ingredients occur. The hot clinker falls from the kiln and either is spread in thin layers to cool or is passed through rotating shells to preheat entering air.

The principal compounds in portland cement clinker are tricalcium silicate, $3\text{CaO} \cdot \text{SiO}_2$ (one half); dicalcium silicate, $2\text{CaO} \cdot \text{SiO}_2$ (one fourth); tricalcium aluminate, $3\text{CaO} \cdot \text{Al}_2\text{O}_3$, and tetracalcium aluminoferrite, $4\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot \text{Fe}_2\text{O}_3$ (one fifth together). A little magnesia, free lime, and sodium and potassium compounds comprise most of the rest. Before grinding, 3 pounds of gypsum are added to each 100 pounds of clinker to retard the setting.

Portland cement is mixed with from three to eight times its weight of sand and rock to form concrete. The volume of water approximately equals the combined volumes of sand and rock. Mixing is in a rotating shell. Setting and hardening result from definite chemical changes. Water combines in hydrates and decomposes silicates and aluminates into compounds with less calcium. Most of the final compounds are colloidal gels which harden slowly. Tricalcium aluminate reacts rapidly with the evolution of heat, but gypsum lessens the rate. The initial set caused by the aluminate is followed by slow changes in the silicates. Tricalcium silicate reacts first, and quick-hardening cements contain extra amounts of this compound. Finer grinding accelerates hardening. Large masses of concrete must be kept cool in summer during initial setting by reducing calcium aluminate proportions or by cold brine in pipes. Where great tensile strength is required, as in construction, concrete is reinforced by corrugated steel rods or bars which have the same coefficient of expansion.

Electric Furnace Products.—Electric furnaces (q.v.) furnish the high temperatures necessary for several important chemical products. Impurities are reduced and removed from aluminum ore in a combination arc and resistance furnace during production of refractory and adhesive grades of alumina. Both graphite and silicon carbide are made in a long resistance furnace. Carbon powder, rods, or plates serve as the resistor. Iron carbides decompose into graphite and free iron, which functions repeatedly. Silicon carbide, SiC , is formed from a mixture of coke, sawdust, and sand around a carbon resistor. A "smothered arc-resistance" furnace makes calcium carbide, CaC_2 , from lime and carbon. Phosphorus results from the reduction of calcium phosphate by carbon in the presence of silicon as a flux. Phosphoric acid is prepared by burning the phosphorus vapors in air, adding water, and collecting the mist of phosphoric acid with electrical precipitators.

Metals and Alloys.—The amount of chemistry involved in smelting and refining operations and the number of chemists employed justify a brief consideration of metals and alloys here.

Arranged in order of maximum production in the United States, magnesium, aluminum, zinc, lead, copper, and iron (q.v.) are the most important metals. The production of other metals sufficiently resembles that of any of these six to make their discussion unnecessary.

Magnesium was produced before World War II only to the extent of a few thousand tons annually. The rapid growth of the aircraft industry and the researches which overcame all the difficulties originally impeding use of this metal caused a vast growth in its production. The total capacity of magnesium plants in the United States was increased to 300,000 tons per year, and at the peak nearly 250,000 tons of the metal were made in one year. Since peacetime requirements were estimated at about 12,000 tons yearly, many magnesium plants became idle after 1945.

The leading process for making magnesium involves the electrolysis of fused magnesium chloride, a large part of the raw material being derived from sea water. Magnesium hydroxide is precipitated from ocean brine by the use of lime and the hydroxide is converted to chloride by hydrochloric acid. This necessitates large chlorine plants, the hydrogen chloride being made by the reaction of chlorine with methane of natural gas. Other processes include production of magnesium chloride from magnesite, with subsequent electrolysis, and reduction of magnesium oxide by carbon or ferrosilicon.

Aluminum is liberated from its oxide in a bath of molten fluorides by electric current. It is also refined by a somewhat similar method. A thin but very impervious oxide layer protects aluminum from corrosion. Its alloys require a coating of the pure metal. About half of all aluminum is alloyed with small quantities of copper, manganese, and magnesium. Yearly production prior to 1940 in the United States averaged around 100,000 tons. During the war this figure was increased tenfold. Processes permitting the use of lower-grade bauxite were developed. Alumina (q.v.) in large quantities was recovered from the "red muds," wastes from previous operations for extraction of sodium aluminate from bauxite. Yearly production of aluminum in the United States averages considerably over 600,000 tons since 1945.

Zinc.—A considerable fraction of zinc is burned in the air to zinc oxide or made into salts. Much larger amounts are marketed as free metal. Zinc sulphide is roasted to the oxide, which is then handled as other zinc ores. The general principle of zinc metallurgy is the reduction of the oxide by carbon in retorts, condensation of the vapors, and burning the waste carbon monoxide. Casting zinc is alloyed slightly. Other metals are often coated with zinc. Brass, a copper alloy, contains about 30 per cent zinc. Production of zinc has at times reached 900,000 tons per year in the United States and in 1949 was about 600,000 tons.

Lead comes largely from sulphide ores. Part of the sulphur is removed and the ore is heated with coke in a blast furnace. A mixture of sulphides, mainly those of copper, is separated from molten lead. Pure lead is the product of an electrolytic process, but most lead is refined in furnaces. Some impurities are skimmed, usually as oxides, and silver is extracted by zinc. Most lead is never alloyed, but some "hard lead" is made by adding antimony or tellurium. Lead is a component of solders. United States produc-

tion varies from 300,000 to 1,000,000 tons, of which less than half is new metal produced from ores.

Copper.—As many as 1,000,000 tons of copper have been produced from ores in this country in a year, but there have been years in which less than one fifth this amount has been produced. Since 1945 production varies between 750,000 and 850,000 tons, or about one third of world production. Approximately as much copper is recovered from scrap as is made from ore. Most copper ores are low grade, but concentration methods such as flotation have made recovery easier. Considerable quantities of copper are extracted with sulphuric acid, but furnace methods are more common. Sulphur is partially removed by roasting concentrates and the ore is processed either in blast furnaces or more commonly in reverberatory furnaces. The first product is a mixture of sulphides of iron and copper. Air is blown through the molten sulphides in a converter until all the iron has lost its sulphur and its oxide has formed a silicate slag. This is poured off and the sulphur burned out to leave a crude copper known as blister copper. Further refining in a furnace removes most impurities, but leaves cuprous oxide dissolved in the copper. This is reduced to copper by the trunks of green young trees. Final refining for metal to be used in electrical transmission and equipment is an electrolytic process, whereby impure copper anodes are dissolved and pure copper is plated on sheet anodes. The major byproducts are nickel, silver, and gold.

Iron.—Production of iron and its alloys, mainly steel, is several times that of all other metals combined. Iron rivals aluminum in abundance and is much more easily recovered from its ores. The magnetic properties of iron have been the foundation of electrical industries. Since iron is easily corroded in moist air, rust losses in the world annually amount to billions of dollars. Scrap iron is remelted so that only a part of production is new metal.

The properties of pure iron are readily changed by small amounts of other elements, particularly carbon. Iron occurs in two modifications with different atomic spacings. The one stable up to 910°C. does not dissolve appreciable amounts of carbon in solid solution, whereas the high temperature modification dissolves this element up to 1.7 per cent. A large part of the physical metallurgy of steel depends on the transformation of one form of iron into another and the effects of carbon. When cooling is rapid, "gamma iron" changes into "alpha iron," but carbon is retained in a supersaturated solution, which is extremely hard. Reheating permits rejection of iron carbide and the steel is softer and more ductile. Other elements are of value chiefly in regulating the transformation of iron, although some form impermeable oxide layers.

Iron ores (largely Fe_2O_3 and silica), mixed with coke and limestone, are heated in a strong current of air in a blast furnace. The product is pig iron which contains as much as 4 per cent of carbon and smaller amounts of silicon, phosphorus, and sulphur. Many articles and machine parts are made from pig iron by casting. Heat treatment makes the crude iron more malleable. Wrought iron is a furnace-refined metal with about 0.1 per cent of carbon and other elements. It is being replaced largely by mild steel.

Steelmaking involves the removal of most of

the carbon and other elements and the addition of the correct amount of alloying substances. In the pioneer Bessemer method of making steel, now used to a relatively small extent, a powerful current of air was blown through the molten metal until the carbon was consumed and the silicon and other elements were oxidized and formed a slag. This required only a few minutes, but was limited to 8 to 15 tons at a "run." Some iron oxide formed, but was reduced by aluminum and other deoxidizers. Alloying elements were added to the molten metal. In the open-hearth process from 100 to 150 tons of metal are handled during a run of several hours. The impurities are removed in a reverberatory furnace by an oxidizing slag, in which iron oxide is dissolved, until about the correct amount of carbon remains. After tapping, deoxidizers reduce the oxides in the final product and alloying elements are introduced. Electric furnaces are increasingly employed in the preparation of special steels.

Production of ingot steel reached a peak of slightly more than 90 million tons in 1944, with a corresponding production of pig iron of 61 million tons. Steel of all types reached a production figure of nearly 78 million tons in 1949, or 81 per cent of capacity. A large part of all steel is made from scrap. See also ALLOYS; STEEL.

Coke and Gas.—All anthracite coal and four fifths of all soft coal are burned directly as fuels. Certain types of bituminous coal are heated to temperatures up to 1800°F. to produce gas and coke. One ton of coal will yield about 1,400 pounds of coke and from 11,000 to 13,000 cubic feet of coal gas. Byproducts include mainly tar, ammonia, and light oils.

Coke.—The larger part of coal carbonization is performed in byproduct coke ovens. These are long, deep, narrow chambers of silica brick which can hold several tons of coarsely ground bituminous coal. From 10 to 50 ovens form a battery. Between and over the ovens are flues, through which burning producer or coke oven gases pass. After 12 to 18 hours of heating, the ends of the ovens are removed and a powerful ram pushes the red-hot coke into a car for transportation to quenching equipment. Coke, being hard, strong, and porous, is good blast furnace fuel. Fusion causes the coke to form long, irregular blocks.

The gas passes through a purifying operation whose completeness is determined by the required quality of the gas and the demand for byproducts. Tar is removed by condensers, perforated baffles, or electrical precipitators. Ammonia is usually scrubbed from the gas by water or sulphuric acid. Sulphur compounds, mainly hydrogen sulphide, are removed if the gas is marketed. Many plants still employ hydrated iron oxide, but in modern processes solutions containing catalysts recover sulphur as a byproduct. Naphthalene is removed to avoid clogging small orifices. If the price justifies, light oils are also recovered. Coal gas has as its main components methane and hydrogen. Its heating value is from 525 to 550 Btu., which means that burning one cubic foot will raise 525 to 550 pounds of water 1°F.

Coke production generally parallels that of ingot steel and in 1944 reached a peak of about 75 million tons. Only about one tenth of this coke was made in the older beehive type of oven. Production in 1949 was about 63.5 million tons. See also COKE.

Gas.—There is not enough coal gas for industrial and domestic needs. In those parts of the

United States where natural gas is not available, large quantities of carbureted water gas are manufactured. Water gas is a mixture of hydrogen and carbon monoxide made by alternate blasts of air and steam through beds of coke or coal. Enrichment to a figure comparable with coal gas is made by adding a rich gas made from petroleum distillates.

Producer gas is a cheap fuel made in the same plant where it is burned. All furnaces are essentially gas producers, the term referring to producing carbon monoxide by the action of carbon dioxide on hot carbon. In a furnace the carbon monoxide burns immediately in additional air. A mechanical producer permits the transfer of the gas to other parts of the plant before it is burned. Air is continually passed through a deep fuel bed. The carbon dioxide formed by combustion is reduced to carbon monoxide. Steam keeps down the temperature at the grate bars and some water gas is formed. If the fuel is bituminous coal instead of anthracite or coke, some coal gas is also made. Producer gas varies in heat value from 125 Btu. to 180 Btu. depending on the fuel.

Petroleum Products.—Until the demand for automobile and aviation fuels became large, the processing of petroleum was largely a matter of distillation, accompanied by some unregulated heat decomposition. In the 1940's the petroleum industry began to become a real chemical industry.

Crude petroleum is composed largely of hydrocarbons with minor amounts of oxygen, nitrogen and sulphur compounds. Only a very small part of the hydrocarbons are aromatics. Paraffins are largely limited to low-boiling substances and a small quantity of crystalline material. Naphthene ring hydrocarbons, many of which have side chains, probably represent the largest quantities of hydrocarbons in petroleum.

Distillation separates crude petroleum into typical fractions including naphthas, kerosene, gas oil, and lubricating stock. Though some batteries of shell stills have not been discarded, all refineries built since 1940 are equipped with pipe stills, or coils of pipe in a furnace. Fractionating columns permit the separation of the various fractions. The higher-boiling fractions are usually distilled under reduced pressure.

Even the best crudes contain insufficient amounts of gasoline to meet modern industrial demands. It is, therefore, necessary to break larger molecules into smaller ones. This was originally accomplished by heat and pressure alone, a process called pyrolysis (or more commonly cracking). Since more recently catalysts such as silica impregnated with phosphoric acid and more commonly various types of silicates are employed, purely thermal cracking is no longer the predominant process. Several of the largest catalytic plants in the United States use a process in which the catalyst in the form of a dust is carried as a suspension in the hydrocarbon vapors. The mixture of dust and gas flows as a fluid and requires very little pumping, the heavier column of dust-laden gas being balanced against a rising column of dust-free gas. Reaction occurs in chambers, wherein the turbulence maintains very even temperatures. Pressures in the process are very low in comparison with the older thermal cracking processes. The catalyst is readily recovered in cyclone collectors aided by electrostatic separators. Catalytic processes are

said to be very versatile, producing at will aviation gasoline, aromatic hydrocarbons for explosives, or olefins for the synthetic rubber industry. The fluid catalyst technique has been extended to the production of phthalic anhydride from naphthalene and probably will prove useful to the chemical industry in general.

Saturated hydrocarbons are converted in vast quantities to unsaturated hydrocarbons by catalytic dehydrogenation. But it is often necessary to add a limited amount of hydrogen to certain reaction products before they are ready for use as aviation fuels. Even in the dehydrogenation operation considerable amounts of hydrogen must be present to control the reaction and to prevent its going too far. Many unsaturated hydrocarbons, mainly butadiene and ethylene, are raw materials for the synthetic rubber industry. Others are starting substances for making gasoline blending agents.

A reaction of great value in the production of the branching chain hydrocarbons so essential in the prevention of knock in internal combustion engines is known as alkylation. This involves the addition of such isoparaffins as isobutane and isopentane to unsaturated hydrocarbons, mainly butylenes, to form saturated hydrocarbons of the desired structure. Alkylation is accomplished by heat alone or more commonly by sulphuric acid or liquid hydrogen fluoride.

Unsaturated hydrocarbons with short branching chains are caused to polymerize to form longer branching chain hydrocarbons, which are liquids. These are hydrogenated to become valuable blending agents for aviation gasoline. Typical among these are iso-octane and triptane. Often two different olefins combine to form what are known as dimers. These operations are also conducted either under the influence of heat alone or with the assistance of catalysts containing phosphoric acid, silica, and pyrophosphates.

To secure an ample supply of isoparaffins the abundant straight-chain butane and pentane are subjected to mild heating in the presence of hydrogen chloride and aluminum chloride contained in fused antimony chloride. This process is known as isomerization and has greatly increased the production of aviation fuels.

Aromatic hydrocarbons are made from straight-chain paraffins by first causing the formation of cyclic hydrocarbons known as naphthenes or cycloparaffins. These are then robbed of some of their hydrogen by controlled reactions in the presence of hydrogen and catalysts until they become aromatic hydrocarbons of the same type as those gotten from coal gas and coal tar. It is estimated that to supply the aromatic hydrocarbon, toluene, for the manufacture of TNT, if it could not have been made from petroleum distillates, it would have been necessary to have increased the present coke oven capacity of the United States about 300 per cent. Obviously this would have been impossible, when it is remembered that a ton of coal yields only about one half gallon of toluene. Other aromatic hydrocarbons such as cumene are excellent blending agents in aviation gasoline. Cumene is made by combining petroleum refinery gases with benzene from coal gases.

These chemical processes yield substances of known composition and structure which are mixed with approximately equal amounts of straight run or cracked gasoline and a little lead tetraethyl to produce aviation gasolines permitting the

high speeds necessary in modern warfare. These fuels are entirely unsuited to automobile engines (as constructed up to 1951), since much smaller quantities of the blending agents are sufficient to make the highest grade gasoline which these engines are capable of using. Future automobile power plants probably will demand increasing quantities of the materials used so abundantly in aviation gasoline, with consequent increase in power and smoothness of operation, so that the developments of the war period will continue to be fruitful.

In the meantime motor fuels from petroleum may be increasingly supplemented by products derived from the action of hydrogen on carbon monoxide. Both these starting substances are readily produced from coke and steam. Such processes were used extensively in Germany during World War II. Since then these processes have been greatly improved in the United States, where several plants, both private and governmental, have been operated with the production of motor fuels and synthetic organic chemicals in commercial quantities. Because of the abundance of natural gas, methane has been substituted for coke as the source of carbon in these pioneer plants.

Certain types of hydrocarbons, particularly straight chain paraffins, cause "knocking" in automobile engines. This phenomenon is a sudden sharp detonation in which the rate of burning becomes extremely rapid. Addition of a small amount of lead tetraethyl, $\text{Pb}(\text{C}_2\text{H}_5)_4$, which must be dissolved previously in ethylene dibromide, greatly reduces the knocking tendencies of ordinary gasoline. Clustered branching chains have the least tendency to knock. Normal heptane, C_7H_{16} , produces very severe knocking and is given a rating of zero, while 2,2,4-trimethylpentane, or iso-octane, rated at 100, will not knock except under very high compressions. If a fuel just barely causes knocking under the same conditions whereby a mixture of 70 per cent iso-octane and 30 per cent heptane will produce the same effect, the fuel has an octane number of 70. Toluene, an aromatic hydrocarbon, has a rating of 110, and 2,3-dimethylbutane a rating of 120.

Gumming and discoloration are prevented by adding very small amounts of aromatic amines and phenols to gasoline. The cost of such materials in a single year is about \$10,000,000, but the resulting saving is probably twice this figure.

The refining of petroleum products is also accomplished by treatment with chemicals. Gasoline is washed with sulphuric acid and a solution of litharge in caustic soda. Sulphuric acid and liquid sulphur dioxide are both employed in refining kerosene. Sulphuric acid washing of automobile lubricants is supplemented by removal of undesirable substances with liquid sulphur dioxide, furfural, dichloridethyl ether, nitrobenzene, and liquid propane.

An important use of gasoline in World War II was as the fuel of flame throwers which were carried either by troops or by tanks. The gasoline was formed into a tough and stable jelly by aluminum soaps of fatty acids, so that four fifths of the burning material reached its target rather than being consumed on the way. Jellyed gasoline was also an ingredient of most incendiary bombs used during the later part of the war.

Large quantities of isopropyl and other alcohols are made by treating refinery gases with sulphuric acid and hydrolyzing the acid sulphate.

Some of the solvents and reagents used in processing petroleum distillates are themselves petroleum products. Impressive numbers of chemicals for other industries are made from petroleum hydrocarbons, beside large quantities of solvents obtained by direct distillation. See also PETROLEUM.

Rubber.—The chief ingredient of rubber articles is a highly polymerized hydrocarbon comprising many C_5H_8 , or isoprene, units. This substance is obtained principally from the latex of the hevea tree (*Hevea brasiliensis*). Most rubber plantations are in southern Asia, but cultivation is being expanded in Africa and in Brazil. After formic and acetic acids have coagulated the latex, the resulting plastic solid is washed and dried. Some latex is spray-dried and some, preserved by addition of chemicals, is employed directly in industry. Crude rubber contains small amounts of salts, proteins, sugars, and resinous substances.

Rubber alone is not a satisfactory material because of its sensitiveness to heat and cold. Charles Goodyear (1800–1860, q.v.) is credited with the discovery that combination of rubber with sulphur greatly extends the temperature within which rubber remains tough and elastic. The process by which rubber is thus changed is called vulcanization. Soft-rubber products contain from 0.5 to 5.0 per cent of sulphur, while hard rubber has in it from 25 to 32 per cent sulphur. Other substances mixed with raw rubber in compounding are: pigments, such as carbon black and zinc oxide; colors; and tars, oils, or resins as softeners. Very small amounts of organic nitrogen and sulphur compounds regulate the rate of vulcanization and are called vulcanization accelerators. Other substances in small amounts prevent premature vulcanization and avoid cracking and disintegration because of air and light.

The rubber and other ingredients are thoroughly mixed on rolls or in powerful, closed, kneading machines, are shaped by sheeting, molding, or extrusion, and are vulcanized by heat and pressure.

Both latex and rubber suspensions in solvents are employed in processes for coating metals, impregnating cord and fabrics, and making thread, rubber gloves, and many other thin-walled articles. These processes include evaporation of solvents, coagulation by acids or zinc salts, and passage of an electric current to cause depositions on zinc forms or metals coated with zinc.

In 1941 the United States was consuming natural rubber at the rate of 800,000 tons annually. The Japanese attack at Pearl Harbor in December of that year automatically cut the United States rubber imports from the Dutch and British East Indies to a trickle. There was on hand at that time a stockpile of 700,000 tons which, with imports during the entire war period of only a fraction of a normal year's supply, served to supplement the enormous synthetic rubber program. Recovery of rubber-producing regions has been surprisingly rapid, and the United States imported 734,821 long tons of natural rubber in 1948.

Synthetic Rubber.—Within five years after imports of natural rubber had ceased, American chemists and chemical engineers succeeded in creating a new industry capable of producing annually as much synthetic rubber as the whole world had consumed of natural rubber in any

year before 1941. Until the beginning of World War II a few thousand tons per year of specialty rubbers, such as thiokol, koroseal, and neoprene, represented the entire synthetic rubber industry. The United States was wholly dependent on imported natural rubber for its tire, tube, footwear, and other fabricating industries. In 1944 nearly 800,000 long tons of synthetic rubber were synthesized, of which about 90 per cent was of the Buna S or GR-S type. The return of natural rubber led to the decline of the government-subsidized, but privately operated, synthetic rubber industry, which since 1945 has produced about 400,000 long tons annually.

In this connection it is interesting to note that the production of neoprene, the first successful synthetic specialty rubber developed in the United States in 1930, has reached since the war the rate of 60,000 long tons per year. Neoprene is made by polymerizing 2-chlorobutadiene, which in turn is made from monovinylacetylene and hydrogen chloride. The original raw materials are thus coal, limestone, and salt. Neoprene is superior to natural rubber with respect to resistance to heat, sunlight, oils, and chemicals.

This almost miraculous feat of industrial production was accomplished by selecting a single process and centering all efforts on that process. Butadiene, made from alcohol and from refinery gases, and styrene, made from coal gas benzene and ethylene from alcohol or refinery gases, are combined in the proportions of 3 to 1 in the presence of soapy water containing minor amounts of chemicals to form a latex, which is later coagulated to a mass of crumbs. The most recent process is a continuous one, considerably increasing the rate of production. The larger part of the equipment and operations in this process is required in making butadiene and styrene.

The product, Buna S or GR-S rubber, is not an exact replacement for natural rubber. In some respects the new material appears to be superior and in others it is not equal to the natural product. When it is remembered that the industry has had 100 years' experience in compounding and fabricating natural rubber as against less than 10 years' trial of the new product, comparisons are somewhat premature, and of little value.

The most significant advance in the process for making GR-S rubber has been to control polymerization at temperatures much lower than the original figure of 120°F. or thereabouts. The newer type of "cold process" rubber is commonly made at 41°F. and some is made as low as 14°F., in this case methanol being added to the reaction mixture as an antifreeze. Cold rubber is distinctly superior to the older types and fully half of synthetic plants operating in 1950 have been converted to this process.

An important ingredient in the manufacture of rubber products is reclaimed rubber. This is not wholly a substitute for new rubber, but is essential because of its peculiar properties in making certain types of rubber products. The technique of reclaiming scrap and waste rubber made from the natural variety is not wholly applicable to reclaiming synthetic rubber, but considerable progress has been made in adapting former methods and developing new ones for synthetic reclaim.

Synthetic Buna S latex compares favorably with the latex obtained from hevea trees, and considerable quantities are being used. A

portant use of latex is in impregnating cotton and rayon tire cord.

Butyl rubber, made by copolymerizing butadiene and isobutylene, is a material in which there is relatively little unsaturation. This rubber, which is strictly an American product, is specially suited to the manufacture of inner tubes for tires. These tubes hold air much better than those made from any other type of rubber and also hold helium remarkably well. Substitution of helium for air in large airplane tires means a noteworthy saving in weight. Butyl production amounts to about 70,000 long tons annually.

Other rubberlike substances are made from vinyl chloride, acrylonitrile (with butadiene to form buna N), isobutylene (with isoprene to form vistanex), and a variety of halogenated organic compounds with sodium tetrasulphide. The last-named substances have the trade name thiokol. The halogens are removed by combination with sodium, leaving sulphur in the molecules of the plastic, which then polymerize.

Plastics made in smaller quantities than buna S have special properties (such as resistance to oils, acids, and other chemicals) which have made them uniquely useful in many industries and in the fabrication of many articles. Quite often a small quantity of one or the other of these elastomers is the key to the satisfactory functioning of an entire piece of equipment. See also RUBBER, SYNTHETIC.

Oils, Fats, and Waxes.—Comparatively little in the way of chemical change characterizes the production of oils, fats, and waxes from natural sources. Important animal fats are tallow, lard, and butter. Most animal oils are fish oils. Vegetable fats are of minor importance. Olive oil and palm oil are made from the fleshy portions of the fruit, but most vegetable oils come from the seed kernels. Small seeds are crushed, but larger ones are broken up and the oil-bearing portion is separated. Edible oils include cottonseed, olive, peanut, corn, soybean, coconut, sesame, and palm. The two leading edible oils are soybean oil and cottonseed oil. The peak in production of cottonseed oil in the United States occurred in 1926, when 1.8 billion pounds of this oil were extracted from the seed. Due to reductions in the amount of cotton grown, the amount of soybean oil produced yearly exceeds that of cottonseed oil. Average figures for annual production in the late 1940's are: cottonseed oil, 1.1 billion pounds; soybean oil, 1.5 billion pounds. Linseed, tung (China wood), oiticica, and castor oils are the chief technical oils. Over 500 million pounds of linseed oil are made in the United States in an average year. Edible oils such as cottonseed oil are refined by treatment with dilute solutions of caustic soda, bleached by activated clays and chars, and are deodorized under reduced pressure by steam.

During World War II imports of oils and fats were cut to a very low figure, particularly those of Asiatic origin, such as coconut oil and tung oil. Imports of oils and fats in the 1937-1941 period exceeded exports by 1.5 million pounds yearly. During the war there was a world shortage of oils and fats. The United States normally imports the larger part of its supply of olive oil and all of its coconut oil. Only limited quantities of tung oil are produced from American-grown nuts. Both flaxseed and linseed oil imports are necessary to supplement the American supply. The United States ordi-

narily produces about 85 per cent of all the oils and fats consumed in the country and can produce all the edible glycerides required.

Waxes such as carnauba and candelilla are obtained from the leaves of tropical plants by scraping and melting. Beeswax is essentially a vegetable product.

Oils are converted into semisolid fats like lard and tallow by heating them with freshly reduced nickel and passing hydrogen under pressure through the liquid.

Fatty acids are minor products of oils and fats. Edible oil-refining residues (or "foots") are common sources of these acids, which are liberated by mineral acids. Garbage greases and wastes are broken up by enzymes or chemicals into glycerin and fatty acids, both of which are readily purified by distillation. Solid acids are called stearic acid and liquid acids are called oleic acid, although other acids are present. Fatty acids are ingredients of candles, polishes, rubber mixtures, pharmaceuticals, cosmetics, soaps, paints, and textile and leather finishes.

A shortage of drying oils during World War II was responsible for such improvements as dehydration of castor oil to produce additional unsaturation, and fractional separation by distillation under reduced pressure of unsaturated fatty acids from a mixture of acids derived from semidrying and nondrying oils. These acids were esterified with glycerin to produce synthetic drying oils.

Double bonds in soybean and linseed oils are shifted by the use of nickel oxide on carbon black as a catalyst; the resulting product is "bodied" by heat without serious loss, as is the case with alkali-refined oils. Paints made with these oils also set faster than those containing the usual type of paint oils. Fatty acids whose double bonds have been shifted to the conjugated position are esterified with polyhydric alcohols. Mild selective hydrogenation of tallow produces a material which gives a better soap for use in the synthetic rubber industry. Selective hydrogenation serves to prevent separation of oleic acid in cold pressing or fractional crystallization of fatty acids from solution. Solid and liquid fatty acids, on the other hand, are efficiently separated and separately esterified for specific purposes.

Soap and Glycerin.—Some aluminum, zinc, lead, and other heavy metal soaps are employed in industry, particularly in lubricating greases, but most soaps are sodium or potassium salts of fatty acids. Pine rosin forms a complex acid whose sodium salt is an ingredient of yellow laundry soap.

Tallow is the principal soap fat. Olive, palm, and coconut oils are valuable soap oils. Vegetable oils and fish oils are hydrogenated to substances resembling tallow. Some refinery foots are made into soaps.

The essential principle of soapmaking is heating oils and molten fats with caustic soda or caustic potash solutions. Addition of salt to the soap kettle causes a separation of soap curds. In the 1940's the old kettle process was being rapidly supplanted by continuous processes involving either production of fatty acids by high-pressure hydrolysis followed by alkali neutralization or countercurrent saponification in centrifuges. Further steps are washing, mixing with colors, perfumes, and other ingredients, drying, and finally shaping into cakes. Soap is also

marketed as a powder, as tiny, thin-walled bubbles, as a paste, and as solution in dilute alcohol.

Sulphonates and alkylaryl sodium sulphates are more expensive cleansers or detergents. These are derived largely from high-pressure hydrogenation of fatty acids to alcohols and, since 1940, more commonly by direct synthesis from petroleum hydrocarbons. They are specially useful in hard water, since their calcium and magnesium compounds are soluble. In spite of the higher price, the newer detergents are produced in quantities exceeding 700 million pounds per year. Closely akin to these are "wetting agents," which facilitate the penetration and wetting of surfaces which repel liquids. The public became aware of them through the duck which sank in water containing a wetting agent.

Glycerin is a byproduct of the fatty acid and soap industries. Unless the price is attractive, some glycerin is wasted in making soap. Washings containing glycerin are chemically treated and then concentrated, pure glycerin being separated by steam distillation under reduced pressure. Glycerin is also made by fermentation of sugar or is synthesized from petroleum refinery gases.

Sugar and Starch.—Carbohydrates are composed of simple or complex ring systems. Their chemical behavior is largely due to hydroxyl (OH) groups giving them an alcoholic character and to the carbonyl (C=O) groups developed by breaking rings. Sugars, starch, and cellulose are the best known carbohydrates.

The most important of many sugars is sucrose, $C_{12}H_{22}O_{11}$, which is present in sugarcane and sugar beets in commercially profitable quantities. This sugar is broken up by acids into the simple sugars: dextrose (corn or grape sugar) and levulose (fruit sugar). Both have the formula, $C_6H_{12}O_6$.

Sugarcane, grown extensively in semitropical and tropical regions, contains sucrose to the extent of about one seventh of the weight of the trimmed stalks. The cane is shredded, pressed, and freed of remaining sugar by addition of water and further pressing. The juice is clarified by lime, carbon dioxide, sulphur dioxide, and phosphates; it is concentrated by evaporation under reduced pressure to practically molten sugar, from which a crude brown sugar crystallizes. Heavy black molasses is a byproduct. Brown sugar is shipped to central refineries where decolorizing and recrystallizing operations result in a pure, white, crystalline product.

Sugar beets are cut into thin slices and the sugar is extracted from them by hot water. The extract is clarified in much the same way as is cane juice; evaporation and crystallization operations are similar. A white sugar is the final product. Beet molasses still contains considerable amounts of sucrose, whereas cane molasses consists mainly of dextrose and levulose. Treatment of diluted beet molasses with quicklime causes the precipitation of insoluble sucrose derivatives, from which the sugar is freed by carbon dioxide.

Starch is a complex carbohydrate composed of dextrose rings. Most commercial starch in the United States comes from corn (maize), although some is made from white potatoes and a very limited amount from sweet potatoes. The corn is softened in warm, dilute sulphurous acid, coarsely ground, freed of the tough, oil-bearing

germ and bran; the starch is separated from the protein material (gluten) by settling.

Gums and adhesives are made from starch by mild treatment with acids. The chief products are British gums and dextrin. More vigorous treatment of starch suspensions with acid solutions under pressure produces a mixture of carbohydrates including dextrin, maltose, and dextrose. The free acid is neutralized with soda, the solution is decolorized and concentrated by evaporation at low pressure to a sirup which is generally known as glucose or corn sirup. Longer boiling at higher pressures finally converts all the starch to dextrose, which is finally isolated and marketed either as anhydrous dextrose or as a crystalline hydrate under the name of corn sugar.

A somewhat similar procedure is employed with inulin, a carbohydrate found in such tubers as the Jerusalem artichoke, to prepare levulose. This sugar is present in fruits and is also formed from sucrose, but neither of these sources is economically interesting.

Alcohols.—Among several commercial alcohols the one made in largest amounts is ethyl alcohol, C_2H_5OH , often called grain alcohol. Before 1940 the larger part was made by fermentation of sugars. Fruits and grains in normal times are the common sources of alcoholic beverages, the chief source of fermentation alcohol being cane or beet molasses. During World War II this source was entirely inadequate because of the shortage of tankers for transportation from the Cuban sugar mills and particularly because of the great demand of the synthetic rubber program. More than half of the butadiene used to make buna S synthetic rubber was derived from industrial alcohol, the remainder coming from the petroleum industry. For these reasons the larger part of all industrial alcohol was made in the war years from grain.

The starch of grain is converted by enzymes to fermentable sugars which are in water solution. Blackstrap molasses is diluted and acidified to break up sucrose into invert sugar. Addition of yeast and ammonium sulphate precedes the fermentation process, which results in alcohol with the evolution of carbon dioxide. The final products, 95 per cent alcohol and 100 per cent of "absolute" alcohol, are obtained by distillation, the removal of the last 5 per cent to produce the latter grade requiring the use of benzene.

A 50 per cent by volume solution of grain alcohol in water is "proof" or 100 proof; absolute alcohol is 200 proof.

Before World War II the production of alcohol averaged annually 100 to 125 million gallons of 95 per cent material. Production in 1944 approximated 600 million gallons. Of this about one tenth was synthetic alcohol from ethylene. But the declining demand for butadiene for synthetic rubber completely changed the industrial alcohol situation. Of the 170 million gallons made in 1949, only 40 per cent was from fermentation processes, while the rest came from the action of sulphuric acid on ethylene and subsequent hydrolysis. Ethylene is a byproduct of the petroleum refinery.

Butyl, isoamyl, and other primary alcohols are also fermentation products. Secondary and tertiary alcohols are usually synthesized from petroleum refinery gases. Of these alcohols isopropyl is the most important and is produced at an annual rate of over 100 million gallons.

The simplest of the alcohols is methanol, CH_3OH . The term wood alcohol, as applied to this very toxic substance, is being discarded to avoid confusing it with grain alcohol. Until about 1920 practically all methanol came from wood distillation, but by 1949 nearly nine tenths of all methanol was synthesized at high pressure from hydrogen and carbon monoxide (water gas). The catalyst for this process contains zinc and chromium oxides. Total production of methanol in 1949 was about 125 million gallons.

Pulp and Paper.—Some paper is made from cotton and linen rags, but the larger part of it is a product of wood fiber. Mechanical wood pulp (or ground wood) is the principal ingredient of newsprint and other cheap papers. The better grades of paper are mainly made from chemical wood pulp.

Wood chips are heated under pressure in solutions of chemicals until the other portions of the wood are partially or wholly dissolved from the cellulose. The chemicals used are: sulphurous acid and calcium bisulphite (sulphite process); sodium hydroxide (soda process); and sodium sulphide and sodium hydroxide (sulphate process). Sodium sulphate, later reduced to sodium sulphide, gives the name to the sulphate process.

Regulations on stream pollution may make it necessary to evaporate sulphite liquors, with the recovery of a pitch and several valuable lignin derivatives. One of these is vanillin, also made from vanilla beans. Both soda and sulphate liquors are concentrated, the organic material burned, and the resulting ash used again in preparing solutions for the digesters.

The fiber is bleached with hypochlorites, freed of water, and formed into sheets unless a paper mill is near.

Several other substances are included with cellulose fiber in finished paper. These are: size, made from pine rosin, soap, and alum; pigments, such as white clay, talc, whiting, gypsum, and zinc and titanium compounds; and dyes.

The operations of screening, mixing the fibers with other ingredients, cutting and fraying them, and causing them to form a continuous sheet of paper or thicker paper board are all strictly mechanical operations. Coatings containing gelatin, casein, starch, and pigments are often applied after fabrication. See also PAPER.

Wood Distillation.—Hardwoods are still the source of considerable quantities of wood charcoal, acetic acid, methanol, and minor solvents. The wood is heated in closed ovens for several hours. Gas of fair fuel value escapes and is burned around the ovens. The distillate is separated by settling and further distillation into tar, oils, acetic acid, methanol, and small amounts of other organic liquids. The charcoal is cooled in airtight chambers. Much acetic acid is made from calcium carbide. Most methanol is also synthetic. Methanol from wood, because of an odor due to minor impurities, is a valuable denaturant of ethyl alcohol.

Turpentine and Rosin.—When the wood of living pine trees is chipped to a slight depth, a liquid, which is the source of turpentine and pine rosin, exudes. Collection is in earthenware cups. Distillation removes the turpentine and leaves a residue of solid rosin. Smaller amounts of turpentine and rosin are extracted by steam and solvents from dead pine stumps.

Turpentine is mainly pinene, $\text{C}_{10}\text{H}_{16}$, and rosin

consists of anhydrides of complex organic acids. The chief use of turpentine is in paints and varnishes; rosin is important in the paper and soap industries. Smaller quantities of rosin are combined with glycerin in varnish manufacture. About 30 million gallons of turpentine and 500,000 tons of rosin represent typical yearly production of the naval stores industry in the United States.

Textiles.—The two major vegetable textile fibers are cotton and linen. Both are composed mainly of cellulose. The fibers are freed from waxes and oils by dilute alkaline solutions and are bleached by hypochlorites. Cotton and linen are disintegrated by even dilute acids.

Wool is a protein. As it is sheared from the sheep, it contains dirt, salts from dried perspiration, and wool fat, a source of lanolin. Washing with warm soapsuds removes foreign matter. Wool is very sensitive to alkalies, but withstands dilute acids.

Crude silk consists of two types of proteins: fibroin and sericin (silk glue). As the liquid secreted by the silkworm is extruded in two very thin streams, the fibroin solidifies and is covered by the sericin; thus the two parallel fibroin filaments are joined. Much of the sericin is removed from raw silk by warm soapsuds before its manufacture into fabric. Silk absorbs considerable quantities of tin and iron salts, which give definite properties to fabrics.

Rayon is made from cellulose by converting it into a derivative which can be dissolved or dispersed in a liquid and extruded to form a continuous filament. Rayon first was made by converting cellulose to the nitrate by treating cotton linters with nitric and sulphuric acids. The thoroughly washed nitrate was dissolved in alcohol and ether and the liquid was extruded through very fine holes in platinum into the air. The filament was formed as the solvent evaporated. Treatment with sulphides removed the nitrate radicals so that the final product was chemically identical with the original cellulose. This process is obsolete.

Some rayon is made by dissolving cellulose in a solution of copper ammonia hydroxide, $\text{Cu}(\text{NH}_3)_4(\text{OH})_2$, and extruding the liquid into an alkaline bath. All copper and ammonia are removed.

Still larger amounts of rayon are made by the acetate process, which is rapidly increasing in importance. The cellulose is converted to the triacetate by acetic anhydride in acetic acid solution containing a little sulphuric acid. The triacetate is then partially hydrolyzed and the product is precipitated in water. An acetone solution of the acetate is extruded into warm air. The final product is still an acetate.

The larger part of all rayon is made by the viscose process. Cellulose in the form of cotton linters or wood pulp is treated with strong caustic soda, the excess of solution pressed out, and the alkali cellulose is dissolved and slightly oxidized. Carbon bisulphide reacts with this material and the xanthogenate is dissolved in dilute caustic soda. The solution attains the proper viscosity and most of the sulphur is removed. Spinning, as extrusion is often called, is into an acid bath. With removal of the last traces of sulphur, the product is a modified cellulose. Yearly production of rayon of all types averages 1.2 billion pounds.

The most recent types of textile fibers are essentially extruded and solidified molten plas-

tics. Nylon is a polyamide derivative made from dibasic acids and aliphatic amines containing two NH_2 groups. These combine to give products resembling proteins, since there is extensive polymerization to molecules of great size. After the polymer has been melted, it is formed into ribbons and then into chips. These are again melted and the liquid is extruded into the air. It solidifies as a tiny filament, which is later stretched, twisted, and made into yarn, thread, and fabrics. During World War II practically all nylon disappeared as a domestic textile because of military needs. Its uses included tire fabric, tow ropes, parachutes, shoestrings, and many other articles requiring an exceptionally strong, resilient, and resistant material. In peacetime nylon has returned largely to its dual purpose as a plastic and as a textile fiber. Its annual production is about 100 million pounds.

Leather.—Animal skins become very hard when dry and decompose if they are moist. Tanning involves the combination of skin proteins with substances which will form stable and flexible products. Hair and epidermis are loosened and removed by solutions of calcium hydroxide containing sulphides. Enzymes, such as pancreatin, eliminate small amounts of other undesirable proteins. Acids (both mineral and organic) remove residual lime and prepare the skin for tanning.

Vegetable tanning is by the action of complex phenolic glucosides from barks and woods. Skins are progressively moved into stronger tan liquors. Thick hides are packed with tanbark and soaked in tannin solutions. Basic chromium salts are the agents in the chrome tanning process. Combination with proteins resembles the combination of chromium salts with ammonia and involves a sharing of electrons. Other tanning agents are alum, formaldehyde, and cod liver oil. Sodium hexametaphosphate with other tanning agents gives a leather of remarkably fine properties. Leather absorbs oils and greases, is usually dyed, and is generally coated with water-repelling finishes.

Gelatin.—Collagen, a protein material, comes from treatment of skins and sinews with lime-water and from extraction of ground and degreased bones with dilute acids followed by neutralization with lime. Extraction of collagen with hot water produces a solution of gelatin. The finer grades of gelatin are foods, but the commercial variety is made into adhesives, sizes, and coatings for photographic plates and films. Glue, a term often applied to commercial gelatin, strictly refers to all types of adhesives.

Crudes and Intermediates.—A small number of aromatic compounds from light oils and tar of coal gas are known as crudes regardless of their purity. These include benzene, toluene, the xylenes, naphthalene, anthracene, phenol, the cresols, and carbazol. The first three, of which benzene is the most abundant, come primarily from light oils. Naphthalene represents about one tenth of the total weight of coke oven tar.

Although a much larger percentage of organic chemicals is made from petroleum than from coal byproducts, hundreds of different compounds are made from coal tar crudes. They are for the most part nitro, amino, and hydroxy derivatives of aromatic hydrocarbons. Some are employed directly as antioxidants, corrosion and gum inhibitors, vulcanization accelerators, insecticides, pharmaceuticals, and explosives. Many

others are the starting substances from which dyes, resins, and plastics are made. Hence they are called intermediates. Leading intermediates are nitrobenzene, aniline, phthalic anhydride, and betanaphthol. Phenol derived from coal tar is a crude, but if it is synthesized from benzene, it is an intermediate.

Synthetic Drugs.—Many but not all synthetic drugs are derived from coal byproducts. Some are identical with natural products, but many are new compounds. Classified on the basis of their physiological action, the main types are general and local anesthetics, narcotics, hypnotics, analgesics, and protozoacides. The discovery of the action of *p*-aminobenzene-sulfonamide in streptococcal infections was epoch-making. A number of these derivatives of sulfanilamide, all known as sulfa drugs (q.v.), have been prepared, each of which has a somewhat different field of usefulness.

Cessation of imports of quinine and other cinchona derivatives during World War II induced a great deal of research and development in the field of antimalarials. The chief antimalarial which was manufactured on a large scale and sent to personnel in subtropical and tropical climates was atabrine. As early as 1943, the production of this drug, amounting to 2.5 billion tablets, required 3 million pounds of intermediates and 25 million pounds of reagent chemicals.

Antibiotics.—The two leading antibiotics are penicillin salts and the streptomycins. Several other antibiotics, of which bacitracin, aureomycin, and chloromycetin are typical, have been developed. Of these only the last can be made synthetically as well as by fermentation. The biological unit by which antibiotics are measured is 0.6 microgram in the case of penicillin salts. In terms of pounds the annual production of penicillin salts and the streptomycins amounts to about 200,000 pounds of each.

Synthetic Dyes.—The first synthetic dye was made by Sir William H. Perkin (1838-1907) in an attempt to synthesize quinine. Later the constitution of alizarin (a plant product) was found and the same substance was synthesized. Once the structures of compounds characterized by intense color had been determined, the dye industry expanded rapidly. Thousands of new dyes have been synthesized. Dye formulas appear to be bewilderingly complex, but closer examination shows them to contain several relatively simple intermediates. The same chemical compound may have several different trade names.

Dyes are classified both by structure and by use. Some may be applied only to vegetable fibers and others only to animal fibers. Some dyes require preparation of the cloth with mordants (substances which adhere strongly to fibers and in turn absorb dyes). Some dyes are actually made on the fiber, one intermediate being applied and treated with another intermediate. After reduction of indigo (a typical vat dye) to soluble and colorless indigo white the solution is applied to fibers. Oxygen of the air converts indigo white to blue dye. Designs are printed from engraved rolls with the dye in a dextrin paste and also are woven with different colored threads.

Insecticides and Agricultural Chemicals.—An organic chemical known as dichlorodiphenyl-trichloroethane and discovered in 1874 was tested

in Switzerland as an insecticide in 1940. By 1949 it was made in the United States at the rate of 1,500 tons per month. Its tremendous potency against all sorts of insects was responsible for prevention of insect-borne epidemics during World War II and for saving of countless lives. This substance (commonly known as DDT) is employed both as a dust and as a spray; in the latter case it is dispersed by an inert and low-boiling liquid, such as the refrigerant freons (chlorofluoromethanes). Many other chemicals are employed as insect repellents, insecticides, fungicides, bactericides, weed killers, and growth stimulants. Two chemicals very effective in killing rats are sodium fluoroacetate and alpha-naphthyl thiourea. Both are toxic and dangerous to human beings and should be handled only by trained exterminators of pests.

Explosives.—Gunpowder (or black powder) is a mixture of potassium nitrate, charcoal, and sulphur. It is mainly a commercial explosive. The chief propellant is a cellulose nitrate product called smokeless powder. Cellulose nitrate containing 13 per cent or more of nitrogen is freed of water by pressing and by displacement with alcohol and is mixed with ether to a plastic mass. Diphenylamine in small amounts prevents decomposition initiated by traces of nitrogen oxides. Extrusion and cutting shape the powder grains. The smaller sizes have a central perforation, but the larger have seven symmetrically placed holes.

High explosives decompose rapidly and exert shattering action. They are of two types. Dynamites have as their main explosive ingredient glyceryl trinitrate (incorrectly called nitroglycerin) together with sodium and ammonium nitrates and combustible material. The second type is represented by nitroaromatic compounds such as trinitrotoluene (TNT) and picric acid (or trinitrophenol). TNT is generally mixed with 50 to 80 per cent of ammonium nitrate. A very safe explosive, set off only by TNT or dynamite, contains 92 per cent of ammonium nitrate.

Explosions are initiated either by flame from a cap or fuse or by detonation of a small amount of a sensitive and very powerful explosive such as mercury fulminate or lead azide. See also EXPLOSIVES.

The effects of ordinary explosives have been dwarfed in comparison with the effects of relatively small amounts of such fissionable elements as uranium 235 and plutonium. The production of these elements was a joint effort of physicists, chemists, and engineers. See also ATOMIC ENERGY; NUCLEAR ENGINEERING.

Synthetic Resins and Plastics.—The term resin is applied to a number of natural and synthetic products which possess noncrystalline structure, luster, insolubility in water, and hardness. The term plastics conveys the idea of soft and easily shaped and molded articles which harden to the consistency of a resin. True thermoplastics are soft when warm and harden when cooled. Thermosetting plastics are at first soft when hot, but undergo chemical changes, harden while hot, and remain hard and infusible at temperatures short of burning.

Synthetic resins and plastics have been classified as follows: thermosetting resins, thermoplastic resins, oil-soluble or modified resins, and protein plastics. Thermosetting materials include phenolic resins, aminoaldehyde or urea formaldehyde resins and glycerin-phthalate

(alkyd) resins. Dr. Leo H. Baekeland (1863–) made the first successful phenolformaldehyde resin before 1910. Thermoplastic resins are represented by cellulose derivatives (mainly esters and ethers), of which cellulose nitrate, cellulose acetate, and ethyl cellulose are the most important, and by a variety of polymer resins derived from acrylic esters, polyvinyl and polyvinylidene derivatives, coumarone and indene polymers, styrene and polyamides. Nylon, as indicated earlier, is a polyamide derivative and, while it is used primarily in filament form, is also a valuable thermoplastic. Modified rosins are also important plastics. The oil-soluble resins used largely in paints are for the most part modified alkyd and phenolic resins and pine rosin, which has been esterified with glycerin. Proteins from such sources as milk, corn, and soya bean are a promising, but still small, base of plastics. The proteins are hardened by formaldehyde.

Petroleum is the source of an increasing number of resins, originally developed for military purposes but later available for general use. They vary from hard and brittle materials to products with some of the properties of rubber. All are thermoplastic with high flash and fire points and find use as laminants, adhesives, binders, plasticizers, and ingredients of coatings of various types.

Fluorine is responsible for a new and remarkably resistant plastic, polymerized tetrafluoroethylene, which has the trade name teflon. This substance is probably the nearest approach of any carbon compound to the chemical resistivity of gold and platinum. It resists such potent chemicals as aqua regia, sulphuric acid, and concentrated alkali solutions, and is only attacked by molten alkalies. Long exposures to temperatures as high as 300°C. do not damage this plastic solid, which is flexible at -75°C. Its chief use is in resisting heat and solvents and in all types of electrical equipment.

Paints, Varnishes, and Lacquers.—Most of the ingredients of paints and varnishes have been mentioned, including pigments, oils, turpentine, petroleum distillates, synthetic and natural resins, and cellulose esters. Paints are suspensions of pigments in a mixture of oils and volatile solvents. The liquids are vehicles and the volatile materials are solvents or thinners. Small amounts of lead, manganese, cobalt, and iron compounds are driers, increasing the rate of reaction of oxygen with oils to form hardened films. Solvents permit smooth application. Some resins may be included for gloss finishes.

Varnishes are mainly solutions of oils, driers, and resins in solvents. Less important are solutions of shellac in alcohol. Rosin and damar come from living trees. Shellac is produced by insects from the sap of trees in India. Copals, products of prehistoric trees, are fossil resins. Synthetic resins are oil-soluble products of the phenol-formaldehyde or glycerin-phthalic acid types and rosin-glycerin ethers.

Cellulose nitrate and acetate are the main ingredients of lacquers. Pigments, resins, high-boiling plasticizing liquids, solvents for cellulose esters, and thinners are the other components of these protective coatings. See also LACQUERS, INDUSTRIAL; PAINT; VARNISH.

CHEMICAL MINERALOGY. See MINERALOGY.

CHEMICAL SENSE. In physiology, a nervous mechanism or function for reception of, and response to, chemical stimulation. Specifically, chemical sense refers to the nervous process initiated by excitation of special receptors sensitive to chemical substances in solution. One kind of chemical sense appearing universally in the case of body surfaces bathed with solutions of irritants, and, in vertebrates involving spinal, as well as cranial nerves is called *common chemical sense* and is distinguished from the *special* chemical senses, as taste and smell recognizable in man and the higher animals. See also ANIMALS, CHEMICAL SENSE IN.

CHEMICAL SYMBOLS, letters or symbols used in chemistry to designate the various chemical elements. They are merely the first letters of the names of these elements (not in every case of their English name); or when the names of two or more elements begin with the same letter, two letters are used as the symbol, one of which is always the first letter of the name of the element. Generally speaking the letters comprising the symbol are taken from the English name of the element; but in some instances, especially in the cases of metals which have been long known, the symbols are derived from the Latin names: thus we have *Hg*, symbol for mercury, from the Latin *Hydrargyrum*; *Fe*, from the Latin *Ferrum*, for iron; and so on. In a few cases the symbols are deduced from the old German names: thus *K*, the symbol for potassium, is the first letter of the old German word *Kalium*, and *Na*, the symbol for sodium, is from the German *Natrium*. However derived, whether from English, German, Latin or French, the symbols of the chemical elements are universally the same. For a considerable time French chemists employed the symbol *Az* to represent nitrogen, from the name *Azote*, which was given to this element in reference to the fact that it alone could not support life (Greek, *a*, privative, and *zōē*, life); but this symbol is now almost entirely superseded by the letter *N*. The symbols of chemical compounds are constructed by placing together the symbols of their constituent elements, a number being attached to each signifying how many atoms of the element enter into the composition of the amount of the compound expressed by the entire symbol. For it must be understood that chemical symbols have a quantitative as well as a qualitative meaning. When a chemist meets in a chemical treatise with the symbol *O* he knows that this signifies not only oxygen but a certain definite amount by weight of oxygen, *O* always means 16 parts by weight of oxygen, so *Fe* means 56 parts by weight of iron; and so also the compound symbol *Fe₂O₃* means $(56 \times 2) + (16 \times 3) = 160$ parts by weight of oxide of iron. For a further account of the uses and modes of formation of chemical symbols see the article CHEMISTRY.

CHEMICAL WARFARE, a term used to indicate the organized use of chemical materials, rather than explosives, as auxiliary aids for the injury of personnel and materiel of an enemy, by destroying structures and rendering uninhabitable certain areas, all with the view of dispersing and conquering his forces. For practical purposes the agents used in chemical warfare may be classed as: (1) incendiaries; (2) poison gases; (3) smoke. The weapons by which these agents are brought to bear upon the enemy are known as *chemical weapons*. The vehicles containing the material, such as shells, grenades, etc., are included in the term munitions. Aids not strictly chemical but more or less in the same category and used for the same purpose, are those which utilize bacteria that are known to produce disease, to start epidemics among people, animals, and crops. This method of warfare is known as biological warfare. The materials used for carrying on warfare as just described and of providing the means of protection against it, are functions of the Chemical Corps of the United States Armed Forces.

Historical Background.—Among the earliest of chemical weapons used in war is fire, it having survived to the present day. Suffocating gases were in use during military operations of the Peloponnesian War between the Athenians and the Spartans in 431–404 B.C. Thucydides, the historian, has related that large masses of pitch and sulphur were ignited and used during two sieges of the war. The so-called Greek fire was probably composed of powdered resin or bitumen, sulphur, naphtha, and perhaps niter. This material was poured upon dry wood and was extremely effective. There are records that it was used in 673 A.D. during the defense of the Greeks against Saracen hordes. The liquid was poured from ladles, while still burning, or was shot from tubes or from ballistae in the form of flaming arrows carrying tow soaked in the mixture. Greek fire is said to have been used in the Middle Ages, the incendiary being pumped through pipes and sprayed upon the enemy. This device was the forerunner of the modern flame thrower. In more recent times the American Indians used incendiary arrows to fire forts and stockades during the early days of white settlements. In the Crimean War (1855–1857) the British forces engaged proposed to reduce the fortress of Sebastopol by incendiary and gas attacks but the British government declined to permit it. In 1863, during the American Civil War, at the siege of Charleston, shells containing sulphur, niter, naphtha, and lampblack were used with little or no effect on the garrison. In 1871, during the Paris Commune petroleum bomb shells are said to have been fired. The subject of chemical warfare was introduced for discussion at the Hague Conference of 1899. Again in 1907, at the Hague Peace Conference a resolution was passed expressly forbidding the use of poison or poisonous weapons. In 1922, at the Washington Peace Conference, a treaty was signed abolishing the use of poison gas. The use of toxic gases began on April 22, 1915, when chlorine was released by the Germans against the British in the Ypres area and a new weapon was forged which required new tactics of offense and defense among the armies of the world. It should be noted that however barbarous the use of poison gas, it still remains a military weapon, while the poisoning of drinking water in wells or springs has always been regarded as against the

laws and customs of war and as subjecting offenders, if apprehended, to summary trial on the spot.

Incendiaries.—The development of fire-resistant structures, long range artillery, and mobile warfare made the use of incendiaries almost obsolete until the era of the airplane. This event abolished almost at once all ordinary means of protection of the civil inhabitants of a country so that they shared the dangers of a war equally with the military forces. There are several types of incendiaries, varying considerably in weight and in construction. The most common agents are: thermit, magnesium, incendiary mixture, incendiary oil, and napalm.

Thermit incendiaries are usually small, weighing a few pounds only, and are discharged as bombs or as grenades. This bomb will remain active longer than most others of equal weight. It produces a heat sufficient to ignite and consume the casing. During the initial stage, molten incendiary metal is sprayed about over an area with a radius of 50 feet. The bomb will burn for about 10 minutes. Its use is tactical and not directed against personnel although it may cause severe burns. It is especially useful in penetrating any ordinary roofing such as slate or tile, causing serious fires in upper stories. In World War II, in some areas 15 per cent of bombs dropped scored hits on buildings, about one half of these starting fires.

Magnesium bombs are also used as incendiaries and only for tactical reasons. This bomb will cause severe burns if in contact with persons.

Incendiary mixture has a composition that is not disclosed and is used in bombs only. It produces bad burns. **Incendiary oil** is a petroleum bomb which is employed to spread inflammable liquid over a large area near fires already started, in preparation for an attack by thermit bombs. These bombs do not ordinarily carry their own combustible agents. Such bombs may be used to drench the clothing of fire fighters thus incapacitating them from dousing fires. Cardboard disks impregnated with phosphorus were used in World War I by the Germans to start fires in standing crops or farms but are not standard equipment today.

Napalm is a material used to thicken gasoline or use in flame throwers and incendiary bombs. This type of incendiary is very effective when dropped from planes or thrown from tanks. It starts fierce and devastating fires that destroy everything in its path. Although used as a tactical weapon it is greatly destructive to human life when no protection is afforded. The most satisfactory method of fighting a thermit bomb is to control its burning, hasten its destruction, and prevent the fire from spreading. During the initial period of violent sputtering no attack should be made upon the bomb itself and efforts should be directed toward keeping the surrounding area thoroughly saturated with water. After the initial period of several minutes, water may be sprayed directly on the bomb at close quarters. Water increases the activity of the bomb and causes it to burn out more quickly. For the purpose of control a hand stirrup pump was used effectively by the British during World War II. The type most favored was one equipped with 30 feet of hose which conducted a jet of water. The chief advantages of the hand pump are its portability and its easy access to buckets and tanks of water independent of the regular water supply. Another method of dealing with the thermit bomb is to

cover it with sand, making no attempt to accelerate the burning and keeping it merely under close observation. This method is applicable to those cases in which no extensive fire has been started. The only chemical extinguishers that can be used safely are those of the soda-acid type. Carbon tetrachloride is dangerous because if it comes in contact with burning magnesium, phosgene gas will be generated.

Chemical Weapons, Agents, and Munitions.

—An important chemical weapon is the flame thrower. This is an apparatus made in varying sizes and having various ranges. It is equipped with a head carrying a pilot light. The device is highly efficient against intrenchments, pill-boxes, etc. It projects or sprays a flammable liquid consisting of water, gas, tar, and benzene. The liquid is only partially consumed when it strikes, a distinct advantage, since it is desirable to saturate the object with burning liquid rather than to burn it with a momentary flame. A portable flame thrower weighs about 70 pounds and can be carried on the back of one man. It has a sustained rate of about 10 seconds and a range of 40 yards. The mechanized flame thrower weighs several hundred pounds and is mounted on a medium tank. It has a range exceeding 140 yards. A recent development (1952) is a giant flame thrower that is a major advance in engineering. It is built into the M-47 tank and constitutes the main armament. The large cannon carried by the tank has been removed to make room for the flame thrower which itself weighs 50 tons, or more than the weight of the tank on which it is mounted. A tremendous pressure has been built up in the flame thrower so that napalm can be ejected at high speed and at a long range. This is accomplished by the use of a special compressor. The range is said to be several times as great as in any other type. Other chemical weapons used to discharge or burn chemical agents are mortars of different sizes and ranges carrying high explosive shells.

The term *chemical agent* applies to gases of different types and purpose, incendiaries, and screening smokes. The use of atomic weapons is not considered here. *Chemical munitions* are vehicles for projecting, evaporating, or burning the agents just referred to. Under this head are: candles, grenades producing tear gas, colored smoke, etc., and thrown from the hand; rifle grenades of the same character; rockets; smoke pots; shells containing chemicals and gases. Grenades weigh from one to ten pounds. Tear gas released from a grenade burns from one to two minutes. A tear gas candle will burn from three to five minutes. Incendiary containers are marked with a purple band.

War Gases.—These chemical agents fall into two main classes: (1) casualty gases; (2) harassing gases. By *casualty gases* is meant those that inflict severe injury on personnel, even death, in those unprotected or only partially protected. Gases of the first category are further divided into:

(a) Blister gases (vesicants) and choking gases (lung irritants); and (b) nerve gases. (a) The blister gases are mustard gas, distilled mustard, nitrogen mustard, and lewisite. All containers holding these gases are marked with a green band. All gases of this category injure the eyes and lungs and blister the skin, causing deep burns that heal with difficulty. Against unprotected clothing they penetrate to the skin. The effect on

the respiratory apparatus is severe since serous fluid accumulates in the lungs, greatly hindering the respiration. Most blister gases persist for several days in summer and several weeks in winter, remaining active in hollows and woods. They are also referred to as persistent gases. They are generally released as liquids which evaporate slowly. The liquid is dangerous to touch and vapor liberated will immediately contaminate the surrounding area. An area exposed will remain contaminated until complete evaporation occurs, or the gas has been neutralized. Choking gases, such as chlorine and phosgene have little persistence, not more than a few minutes in summer and perhaps 20 minutes in winter. Weather conditions influence the effectiveness of gas. Wind carries it along and volatilizes the liquid more rapidly than is the case in calm weather, but high winds interfere with concentration of gas. In very cold weather liquid gas may freeze. This will prevent gas vapor from forming but the solid released will still inflict severe skin burns. Heavy rain will dissipate gas on the ground but light rain has little effect. Built-in areas that have been gassed are dangerous because the gas remains in high concentration much longer than in open country. (b) Nerve gases. These are blood and nerve poisons perfected especially since 1941. At least three of these casualty agents are available in munitions marked with a green band. They are: cyanogen chloride; hydrocyanic acid gas; arsine. All are lethal agents. Their persistence is limited to about ten minutes except in the case of hydrocyanic acid which may persist for several hours. These nerve gases are highly toxic, having an action like, but more prolonged than, physostigmine. They are readily absorbed by the respiratory tract, skin, eyes, and gastrointestinal tract. The symptoms begin early and progress rapidly, the action of the poison being much the same as nerve insecticides such as parathion and tetraethyl pyrophosphate. Acute poisoning is manifested by excessive stimulation of the parasympathetic system, the central nervous system, and the entire motor nervous system. The group of symptoms resembles muscarine and nicotine poisoning. Loss of appetite, nausea, vomiting, abdominal cramps, and diarrhea are generally present. In addition there occur increase in sweating, lacrimation, a sense of tightness in the chest, and difficult or spasmodic respiration. Patients complain of intense fatigue, muscular weakness, and insomnia. In some cases an intense mental depression is observed. If poisoning is the result of a large dose of nerve gas, the pulse becomes weak or imperceptible, succeeded by convulsions, cyanosis, and involuntary urination and defecation. There is thought to be a narrow margin between the dose that produces moderate toxic symptoms and one that will prove fatal. Repeated exposure to the gas shows that its effects are cumulative. The manner in which detoxification occurs and how excretion of the agents takes place is not known definitely. In large doses all those not protected become casualties, with development of alarming symptoms. Little ventilation of the lungs will be possible on account of the spasmodic closure of the air passages. The number of respirations gradually diminishes and the heart action becomes weaker and weaker. If the effects are not lethal, complete respiratory paralysis does not take place and the subject recovers slowly although the symptoms mentioned persist for some days with

perhaps evidence of some mental derangement. The diagnosis of nerve-gas poisoning is to be made from the characteristic symptoms. The treatment of this type of poisoning is both preventive and active. Casualties from exposure to the gas endanger unprotected personnel, hence handlers should wear rubber aprons and gloves. The free use of water is important to remove agents remaining on clothing or equipment. A gas mask is essential to protect from either vapor or spray. Ordinary clothing gives little protection. Nerve gas can poison both food and water, an important fact to remember. First aid treatment can be divided into life-saving measures and those undertaken for the relief of symptoms. The use of atropine to relieve intermittent bronchospasm, cyanosis, slowed pulse, and depressed blood pressure is advised, about two milligrams being given intravenously every two or three minutes until symptoms are relieved or dryness of the mouth occurs. Some cases tolerate unbelievably large doses without evidence of atropine poisoning. Barbiturates may be given to control convulsions.

Harassing gases.—These are agents which produce incapacity for military action in those who come in contact with them. They are not classed as casualty gases and are best adapted for use in limited areas and in closed spaces, for handling unruly prisoners, subduing riots, disarming small groups, etc. The gases are subdivided into vomiting gases (emutators), and tear gases (lacrimators). These gases produce temporary disability up to 24 hours. Those exposed to vomiting-gas show symptoms of headache, nausea, vomiting, and mental depression. *Adamsite* is odorless or with an odor somewhat like coal smoke and acts within a few minutes. Diphenylchloroarsine has a similar action and odor but produces much more active vomiting. The most effective tear gas is chloracetophenone, a white solid with an odor of apple blossoms. It is used in grenades or pots. Its solution has a sweetish odor of benzene. These gases cause an intense and blinding flow of tears and act within 10 minutes (see table). The gas also irritates the skin but has no permanent effects.

All gases are most efficient when used against unprotected troops and are extremely effective in surprise attacks especially if masks are not available. The effects on civilians in large communities will almost certainly be serious both in casualties and in loss of morale. Detection of gas may be based on odor, immediate visible effects, especially those of irritation, visible signs of injury, and chemical indicators. Proper defense against gas requires thorough training and drill in the use of protective equipment and the understanding of warning alarms. Respirators or masks are of various types. In World War II the British used the following: (1) civilian respirators including those designed for babies and small children; (2) civilian duty respirators for those working in gas-contaminated areas; (3) service respirators issued to the armed forces. All respirators consist of a rubber face-piece covering eyes, nose, and mouth and held in place by a head harness. To this is attached a canister to absorb gases and poisonous smoke. The canister-type is quite generally standardized for present use. The canister contains activated charcoal and lime-soda to absorb gases, and a filter pad for removing solid particles emanating from harassing gases and smoke.

Smoke.—A smoke screen is a device for ob-

TABLE OF WAR GASES

Type	Properties	Odor	Physical Effects	Persistence	Function	Method of Use
Casualty Gases						
Mustard distilled (dichlorodithiylsulphide)	Oily liquid; colorless, volatile.	Garlic or horse-radish.	Injures eyes and lungs; blisters the skin.	3-4 days to 3-4 weeks.	Casualty.	Bomb, artillery, mine, spray.
Mustard	Oily liquid.	Same as above.	Same as above.	3-4 days to 3-4 weeks.	Casualty.	Same as above.
Nitrogen mustard	Same as above.	None or a faint fishy.	Same as above.	3-4 days to 3-4 weeks.	Casualty.	Artillery, mine, spray.
Lewisite (Chlorovinylchloroarsine)	Oily, colorless liquid and gas.	Geranium.	Same as above.	1 day = 1 week.	Casualty.	Same as above.
Choking Gases (lung irritants)						
Phosgene (carbonyl chloride)	Nearly colorless gas.	Musty hay.	Injury to lungs with accumulation of fluid.	5-20 minutes.	Casualty.	Bomb, mortar, rocket.
Blood, Nerve Poisons (paralysants)						
Cyanogen chloride	Colorless gas.	Bitter, irritating.	Injures lungs; causes paralysis.	1-10 minutes.	Casualty.	Bomb, mortar, rocket grenade.
Hydrocyanic acid	Same as above.	Bitter almonds.	Dizziness; paralysis; coma.	1 minute to several hours.	Casualty.	Same as above.
Arsine (hydrogen arsenide)	Same as above.	None or garlicky.	Slows respiration; headache, nausea; anemia, jaundice.	1-10 minutes.	Casualty.	Same as above.
Harassing Gases (sternutators; lacrimators)						
Adamsite (diphenylaminechloroarsine)	Gas or solid.	None or a coal smoke.	Headache, nausea; sneezing.	1-10 minutes.	Vomiting gas.	Candle, grenade.
Diphenylchloroarsine	Colorless solid.	Same as above.	Same as above.	1-10 minutes.	Same as above.	Same as above.
Chloracetophenone	White solid.	Apple blossom odor.	Causes crying; irritates skin.	1-10 minutes.	Tear gas.	Grenade; pot.
Tear gas solution (1) (chloracetophenone) solution	Colorless solution.	Sweetish; benzene odor.	Same as above.	1-50 minutes.	Same as above.	Bomb; mortar.
Tear gas solution (2) (chloracetophenone) solution	Same as above.	Same as above.	Same as above.	1-50 minutes.	Same as above.	Bomb; mortar; spray.

scuring the movements of combatants in warfare. In World War I smoke screens were laid on land by smoke shells or bombs containing phosphorus. Such screens can also be laid by planes flying low or on the water by navy destroyers. Destroyers are equipped with special burners for phosphorus or other chemicals such as chlorosulfonic acid. Both Zeebrugge and Ostend harbors were screened by British forces at the time they were blocked. In ancient times the use of smoke was probably directed more toward its asphyxiating action than to its value as a screen. However, in former days both smoke and fog have decided the issue of many a battle. The invention of smokeless powder came about as a result of the obscurity developing in battles of the Civil War, when only black powder was in use. The use of smoke may be offensive or defensive. When used as a screen it is generally produced by smoke candles, generating tanks, airplanes, and destroyers. As a confusing blanket it is laid by shells and bombs and denies the enemy information, reduces the effects of hostile fire, hampers hostile attacks, and may effect surprise. It may be used for local covering of small areas such as roads and bridges. Smoke is made up of solid or liquid particles and its effectiveness depends upon their size, concentration, color, and persistence. There are many screening smokes listed in the armamentaria of armed forces. Among these are: phosphorus, plasticized white phosphorus, sulphur trioxide, chlorosulfonic acid, titanium tetrachloride, and

hexachlorethane. The first two have an odor of burning matches and, while not poisonous, the solid particles burn the skin. These smokes are released by bombs, artillery, mortars, grenades, and rockets. The smoke persists until the source is consumed. The other agents mentioned have an acrid odor but are not harmful. Fog oil has an odor of oil and is discharged from a mechanical smoke generator. It has no ill effects. Phosphorus smoke shells for use in howitzers and mortars are calculated in rounds per minute per 100 yards of coverage, indicated by quarters of the clock. The smoke produced has both screening and casualty value. Smoke containers for military use are marked with yellow bands. In general, white or light colored smokes are more effective than dark colored or black smoke due to the higher degree of reflection in the former.

Biological Warfare.—This may be defined as the intentional use of living disease agents or their toxic products for the purpose of causing death in man, animals, or crops. It is an attempt to use the forces of nature in war and is directed essentially against persons and especially their food supply. This form of warfare, so naturally abhorrent to the minds of civilized nations, recognizes the possibility of man's using pathogenic organisms as agents in the furtherance of his grim purpose. Three types of agents are at hand, the antihuman, and antianimal, and the anticrop. Of the agents directed toward human beings, it is logical to consider the possibilities existing in

bacteria, viruses, and rickettsia, and perhaps in fungi. Many of these are airborne and are capable of initiating epidemics. Theoretically such agents could be disseminated far and wide by means of aircraft and dispersed in the form of infective clouds which would be colorless, tasteless, and invisible. A second method involves the clandestine introduction of these agents to cause contamination and spoilage of food, air, and water. Such attempts might well fail if attacks were made on well chlorinated water supplies or if foods contaminated were afterward well cooked. While it should never be forgotten that biological warfare could be utilized by enemy forces or by an enemy underground (secret agents, sabotage) it should also be realized that it is no secret super-weapon. While the term "germ warfare" is in a measure explanatory of the character of biological warfare, it is not all-inclusive and the latter term, often shortened to BW, is better. It can be divided into three parts: (1) attacks by living agents such as bacteria and viruses; (2) attacks by toxins and poisons produced by bacterial action; (3) attacks by chemicals known as artificial hormones or growth regulators, such as those used to kill weeds. It should be repeated that biological warfare signifies the *intent* to use these means and to spread epidemics to kill or disable populations. It should never be applied to epidemics occurring as a result of lack of proper sanitary and hygienic measures being taken in the presence of epidemic disease. Except on a limited scale biological warfare has not been used by any of the powers in war and it is to be doubted if this type of warfare could ever decide the issue of a war. Certainly no modern city or municipality could be destroyed by such means. So far as is known there are no mystery germs that could cause a devastating epidemic. In the present state of biological warfare it is well recognized that defensive measures such as regard for public health precautions are important elements in the protection of all communities of the civil population.

CHEMISTRY. Chemistry is a science which deals with the composition, properties, and changes of substances. The ancients possessed considerable factual knowledge of chemical changes brought about in such industries as the winning of metals from their ores, the extraction of dyestuffs from plants and their application to fabrics, the tanning of leather, and the production of glass and pottery, but this information was handed down by generations of craftsmen without either organization or a background of theories and principles.

Egypt was the home of arts involving chemical changes. Its black soil gave it the name of Khem, which became attached to those phenomena and their utilization that are now associated with the science of chemistry.

The contributions of the Greeks were largely confined to thoughts without any amount of experimental evidence. The elements of the Greeks, fire, water, earth, and air, were merely properties of matter.

In the Middle Ages the progress of chemistry owed its small advancement to the practice of alchemy, which had as an objective the transformation of base metals into gold. It has been pointed out by Dr. F. J. Moore in his *History of Chemistry* that the alchemists had logic on their side, since they had seen chemical changes and reasoned that if some substances could change, it should ultimately be possible to convert one metal into another more valuable metal. There was also a great deal of the mysticism of secret and religious orders about the practice of alchemy.

The interest in the search for the gold-transforming philosopher's stone and for the elixir of life shifted in the 15th century to the applications of chemicals in medicine. Georg Agricola (q.v.), a physician who became a metallurgist, was a notable exception in his age.

Robert Boyle, best known for his researches with gases, in 1661 defined an element as a form of matter that had not been decomposed. It was about this time that Georg Ernst Stahl proposed the "phlogiston theory" which explained such reactions as burning or rusting as the loss or gain of a mysterious invisible substance called phlogiston. Mikhail V. Lomonosov, the great 18th century Russian scientist, had ideas about atoms, molecules, and the conservation of matter that placed him a hundred years ahead of his time. The investigations of Henry Cavendish, Karl W. Scheele, and Joseph Priestley regarding hydrogen, chlorine, and oxygen were milestones in the progress of science. Antoine Laurent Lavoisier, who died under the guillotine in 1793, was the greatest figure in the history of chemistry in the 18th century's closing years. His insistence upon weighing and measuring banished the phlogiston theory and vindicated the idea of the indestructibility of matter.

With the beginning of the 19th century, the modern science of chemistry entered a period of growth and development that has continued with increasing vigor to the present day.

Properties of Substances.—In defining chemistry, the terms *substance* and *property* have been used. In the strict scientific sense a substance is more than a form of matter, and has been aptly defined as "a definite variety of matter, all specimens of which show the same properties." Color, taste, and odor are properties of substances. Determinations of the

"Medical Problems in Chemical Warfare," *Journal, American Medical Association*, vol. 144, pp. 606-609, April 21, 1950; "Chemical Warfare" issued by Armed Forces Chemical Journal, April 1952.

Colonel, Medical Corps, United States Army
(Retired); Editor of "Blakiston's New Gould
Medical Dictionary."

odors of some substances and the taste of many more are undertaken with considerable caution because of their possible poisonous character. The weight of a given volume under given conditions, otherwise called *density* or *specific gravity*, is a property of every substance. Water is the common standard of comparison of solids and liquids, while gases are generally compared with hydrogen or with air. The temperatures at which a solid melts and a liquid boils under a given pressure are physical constants that are also properties of these substances.

It is scientifically incorrect to speak of an "impure substance," and both incorrect and tautological to refer to a "pure substance." In the first instance the reference is to a mixture of two or more substances. Substance means only one form of matter, and "pure" is unnecessary.

States of Matter.—Before considering chemistry further, a review of some elementary physics will be helpful. Substances and mixtures of substances, or matter in general, exist in the three states, *solid*, *liquid*, and *gaseous*. The same substance may be in any one of the three states, depending on conditions.

What is commonly thought of as a solid is a form of matter that is sufficiently hard and rigid to retain its shape independent of its surroundings. If no other force than that of gravity is brought to bear on a solid, it shows no tendency to change its dimensions. True solids are crystals that have a definite internal and external pattern, but this distinction need not be made as yet.

A liquid does not change its volume, but it takes the shape of its container. Liquids flow more or less readily, and many of them change rapidly into gases with moderate increases in their temperatures.

Gases fill any container in which they are placed, being readily compressed to smaller volumes, and expanding when pressures are lowered.

Gases at ordinary pressures are regarded as being made up of infinitely small particles called molecules. At the temperatures to which we are accustomed, these molecules are in rapid and continual motion, colliding with the walls of the container and with each other. The temperature of a gas is a measure of the intensity of the motion of its molecules. Pressure of a gas is exerted by the continued bombardment of its molecules against retaining surfaces. The space occupied by gaseous molecules and the attractions between molecules may be neglected as long as only the gaseous state is considered and pressures are not high.

In the liquid state, the molecules are still in motion, but they are so close together that attractive forces prevent the distances between them from becoming appreciable. The molecules slide freely past each other, and thus the liquid flows and there is constant mixing of molecules.

There is motion in the solid state at ordinary temperatures, but this motion is a vibration so that individual molecules do not greatly change their relative positions to each other. In fact, as will be explained later, the distinction of individual molecules is more or less lost, and still smaller units are dealt with, which necessitate chemical rather than purely physical ideas.

The point at which all motion ceases is the *absolute zero*, which is 273 C. (460 F.) degrees

below the melting point of ice at atmospheric pressure (0° C. or 32° F.). At any temperature above absolute zero, there is some sort of motion of molecules or smaller units.

Molecules escape from the surface of a liquid, and in a closed container partially filled with liquid, the rate of escape is quickly equaled by the rate of return of the gaseous or vapor molecules to the liquid state. The higher the temperature, the more rapid is the rate of escape and of return, and the higher the pressure exerted by the molecules of the vapor. There is a similar escape and return from the surface of a solid, although for many solids the tendency is not measurably great.

When heat is applied to a solid, the vibrations of its particles increase in intensity, and at a certain point molecules escape from the surface to form a liquid. At this point the temperature does not rise further until all the solid disappears. Before this happens, if no heat is applied and its escape is prevented by insulation, there will be an equality in the number of molecules escaping or returning to the solid state, or what is known as an equilibrium.

A solution refers to a mixture of molecules of two or more substances. Ions, which are charged particles, made up of one or more atoms function like molecules in solution. Gases mix in all proportions and there are solid solutions, but the term *solution* is generally thought of as a mixture of molecules in the liquid state. Some liquids mix in all proportions, but there is usually a definite limit of the solubility of one substance in another. Solubility changes with temperature, but whether it decreases or increases depends on the nature of the substances involved.

When a membrane is interposed between a liquid that is a single substance and a solution of one substance in another, it often happens that one kind of molecule will pass through the membrane and another kind will not. For example, a solution of sugar in water divided by a membrane from water will lose water molecules from the solution. A definite pressure on the water side is required to cause the water molecules to pass at equal rates through the membrane. This *osmotic* pressure has the quantitative aspects of gas pressures. (See also **MATTER**.)

Characteristics of Chemistry.—Chemistry is primarily the science of the transformations of substances into other substances. Two or more substances may combine to form a new substance; a substance may decompose into other substances; and other changes may take place that seem more impossible and unexplainable. Iron and sulphur are substances with very marked and unmistakable properties. One is dense, gray, and insoluble, and is attracted by a magnet. The other is much less dense, is yellow, is soluble in certain solvents, and is not affected by a magnet. The two substances can be ground and mixed and then separated, either by dissolving the sulphur in carbon bisulphide or by drawing out the iron by a magnet. If the mixture is heated, it will remain hot for some time after the source of heat is withdrawn, and the product has none of the properties of iron or sulphur, but a new set of properties of its own. A red solid known as mercuric oxide is converted by heating into liquid mercury and gaseous oxygen. Metallic zinc dissolves and

CHEMISTRY

disappears in a solution of sulphuric acid in water; gaseous hydrogen escapes; and removal of the water leaves a white solid called zinc sulphate. In this case two substances are converted into two other substances. These are chemical transformations. The melting of iron and its crystallization from the liquid state; the dissolving of sulphur in carbon bisulphide; the passing of an electric current in a coil around a mass of iron to render it magnetic, all are thought of as physical changes. Only when new substances are formed is the field of chemistry really entered. However, there are so many close interrelations among the sciences that it is often very hard to draw sharp distinctions.

A second striking characteristic of all chemical changes is that definite quantities are always involved. Chemical reactions take place according to fixed proportions by weight, and in the case of gases, according to simple volume ratios. For example, slightly more than 2 grams of hydrogen will combine with 16 grams of oxygen to form approximately 18 grams of water. At the same time the volume of hydrogen that combines is just twice that of oxygen. If the two substances were present in different proportions from these, some of one or the other would remain uncombined. The quantities involved have been determined with the utmost care, and the same results have been obtained a great many times, so that the law of definite proportions has been thoroughly established. This law in turn depends on the law of conservation of mass, which is that in any isolated system, or portion of the universe set aside for observation, there is neither gain nor loss of matter. This also applies to energy. A small loss in weight has been observed in connection with atomic fissions and the formation of radioactive elements. This loss in weight is accompanied by evolution of enormous quantities of energy. Instead of considering the two, mass and energy, separately, modern science puts them together in the law of the conservation of mass-energy.

A third characteristic of chemical change is that definite quantities of energy are involved. Heat energy and electrical energy are the two types that are more commonly associated with chemical reactions, although other forms such as light energy or mechanical energy also accompany chemical changes. For example, 12 grams of carbon (graphite) combine with 32 grams of oxygen to form 44 grams of carbon dioxide with the evolution of 94,030 calories of heat.

Elements.—Certain substances cannot be decomposed by any ordinary chemical methods into other and simpler substances, nor can they be made by the combination of other substances. This generalization still holds in the common experience of chemists, and any modifications of this statement will be better understood after simpler and more basic ideas have been presented. These substances that are neither decomposed nor synthesized are called *elements*. Familiar elements are oxygen, sulphur, iron, carbon, hydrogen, and 15 or 20 others, although nearly 100 elements are known. Elements combine with each other to form compounds. On the other hand, compounds may break up into elements. One element may drive another out of a compound and take its place. Two compounds may exchange elements to form new compounds. A certain group of elements may

remain together through chemical changes while other elements in the compound are exchanged or replaced. Such groups are called *radicals*.

Two elements may combine in several different ways to form different compounds. However, it is a striking fact that in such cases, if the quantity of one element in these several compounds is fixed at a certain value, the quantities of the second element in these compounds bear a very simple relationship to each other. For example, 28 grams of nitrogen will combine with 16, 32, 48, 64, and 80 grams of oxygen to form 5 different compounds. There are respectively 2, 3, 4, and 5 times as much oxygen as in the first compound.

Thus it is possible to assign a numerical value to each element that will represent the quantity that will combine with another element. Thus if the value of 16 is given to oxygen, either 16 grams or some simple multiple of 16 represents the combining proportions of oxygen in all of its compounds. (See also **ELEMENTS**.)

Atomic Theory.—These remarkable quantitative relationships characteristic of chemical changes are satisfactorily explained by the atomic theory (q.v.), first proposed by John Dalton early in the 19th century and modified more than one hundred years later by other fundamental discoveries. In its simplest terms this theory may be stated as follows: The elements are made up of exceedingly small particles called atoms that are incapable of further subdivision. The word *atom* means indivisible. Incidentally, the idea of a limit to the subdivision of matter went back to the ancient Greek philosophers, but was without experimental proof. The atoms of one element are all exactly alike, but are different from the atoms of all other elements. Chemical reactions are between one atom of one element and one atom of another element or between very small numbers of each. This accounts for the simple and multiple proportions just discussed. If all atoms of iron have the same weight and this is true of the atoms of sulphur, and if one atom of iron combines with one atom of sulphur to form iron sulphide, then the same weight relations would hold good if a billion billion atoms of iron combined with a like number of sulphur atoms. Also, if 1 atom of oxygen combined in one instance with 1 atom of copper and in another with 2 atoms of copper, the relation between the weights of copper in the two compounds would be the simple ratio of 1 to 2. The atomic theory has had to be modified to a certain extent by the discovery that the atoms of an element are not all alike in weight. What is now called an element is a form of matter all of whose atoms have the same atomic number, that is, the same number of protons in the nucleus and the same number and arrangement of electrons outside the nucleus. These different forms of the same element are called *isotopes*. However, the isotopes of each element are so thoroughly mixed that a very precise value can be assigned to represent their average weight, and this is the value that is commonly given as the atomic weight of an element. This will be discussed more fully as individual elements are taken up. (See page 407b.)

Those values chosen to represent the relative weights of the atoms of the elements on the basis of a great many analyses of compounds have been further confirmed by an observation

first made by the French physicists, Pierre Louis Dulong and Alexis Thérèse Petit, that the products of the specific heats of many elements in the solid state and the weights commonly accepted as representing the combining proportions of these elements have the same value. It would appear reasonable that the same quantity of heat is required to raise equal numbers of atoms of elements in the solid state through the same temperature interval. This principle has been used in determining the correct value to be assigned to a new element.

X-rays are employed to determine the number and arrangement of atoms in crystals. The distance between atoms is of about the same order as the wave lengths of X-rays. By passing X-rays through a thin crystal or reflecting them from the crystal's surface and observing the deflections caused by the atoms, the distances between atoms and the ways in which they are spaced are accurately calculated. The weight of a given volume of metal is easily determined. If the number and spacing of the atoms are known, it is easy to calculate the weight of an individual atom. These weights are extremely small, and it is more satisfactory to assign an arbitrary weight to one atom and obtain values for other atoms that give the relative weights of each. These are known as *atomic weights*. Thus, if the relative weight of the oxygen atom is assumed to be 16 and it is known that an atom of molybdenum weighs exactly six times as much as an atom of oxygen, the value of 96 is assigned to the atom of that element. When definite units are required, that number of atoms is selected that would give the chosen value in a particular unit. The number of atoms of oxygen that weigh 16 grams is the same as the number of atoms of molybdenum that weigh 96 grams. This number is known and has been checked and proved by several independent methods. It is approximately 6×10^{23} , but this value enters into few chemical calculations.

Within the present century the great amount of new information gained about the structure of atoms makes very much more credible the regularities with which different kinds of atoms combine. The phenomena accompanying the discharge of electricity through gases under very low pressures led not only to the discovery of X-rays, or very short wavelength vibrations of the same nature as light, but also to the concept of the electron as one of the fundamental units of which atoms are composed. The discovery of the radioactive elements contributed further evidence to the knowledge of atomic structure. As radioactive elements disintegrate, particles are given off that have several thousand times the mass of the electrons that are also released from radioactive elements. These *alpha particles* are very powerful projectiles, and the extent and frequency of their deflections as they passed through thin sheets of different solid elements and recorded their impacts on a photographic plate gave a picture of the internal structure of atoms. All of this work is too complicated to be considered here, but is merely cited to show the nature of the evidence on which the modern picture of atomic structure is based.

While only very little understanding of subatomic phenomena can be had without abstruse mathematics (some of it specially devel-

oped to account for the behaviors of particles that have no analogy in the movements of objects that can be seen), chemists have made highly simplified pictures of different atoms that enable them to explain many of the facts of chemistry.

Only three kinds of particles are needed to make these pictures of atoms, although other kinds of particles have been discovered. These three are electrons, protons, and neutrons. The *electron*, as far as chemists are concerned, is a particle of about $1/1840$ the mass of a hydrogen atom that has a negative charge. This is the smallest charge that has ever been measured and is regarded as a unit of electrical charge. A current of electricity is a stream of electrons or negative electrical particles. Physicists have a much more complicated idea of the electron, involving the ideas of waves and vibrations, which fits the observed facts, but a very simple concept is enough to satisfy chemists for some time to come. The *proton* is a positive particle that has almost the same mass as the hydrogen atom, but has a positive charge exactly equal to the negative charge of the electron. For a long time chemists were content with these two particles, but a third kind of particle is now employed in describing the inner structure of the atom. A *neutron* also has about the same mass as the hydrogen atom, but has no charge whatever.

The simplest of all the atoms is that of hydrogen, since it is made up of a single proton and a single electron. The two make up a very simple "one sun and one planet" system, the electron moving around the proton as the earth moves about the sun. The distance between the two is relatively as great. The calculations describing the behavior of the one electron, however, would fill many pages.

Another type of atom is approximately twice as heavy as hydrogen but behaves exactly like hydrogen. It is made up of one proton and one neutron, which are very close to each other and which together make up the *nucleus* of the atom. Around this nucleus there moves a single electron just as in the hydrogen atom. As far as everyday chemistry goes, hydrogen as it is liberated from water, acids, or hydrocarbons, is a mixture of about 99.98 per cent of ordinary hydrogen and 0.02 per cent of this other kind of hydrogen called deuterium. The two are isotopes, a term whose meaning will be more apparent later.

The next heavier element is *helium* (q.v.). Evidence for the existence of this element was obtained from the spectrum of the sun some years before it was discovered on the earth. Some natural gas contains as much as 1 per cent helium, and it is now separated in commercial quantities. The helium atom is made up of a nucleus of 2 protons and 2 neutrons around which 2 orbital electrons move. This pair of electrons next to the nucleus represents a balanced and stable arrangement so that helium refuses to combine with any other element. An alpha particle, made up of 2 protons and 2 neutrons, is merely a helium nucleus which has escaped from the large nucleus of a radioactive element. Traveling 20,000 times as fast as a rifle bullet, it is a most powerful projectile. Once stopped, an alpha particle picks up from the abundant supply of stray electrons the 2 electrons that it needs and becomes a harmless

helium atom.

This pair of electrons next to the nucleus is present in all other kinds of atoms heavier than helium. Arranging the atoms in increasing order of numbers of electrons in their orbits, the nucleus of each is also made up of an exactly correspondingly increasing number of protons. The increase in the mass of the nucleus is not regular, but each element has an atom with one more proton and one more electron than the one next below it, and one less of each than the one next above it. After helium, which has 2 electrons, the next element, *lithium*, has a third electron which moves at a considerably greater distance from the nucleus than the other two. Eight electrons represent the limit of this second planetary system or state. A new system begins until the limit of the third orbit's capacity is reached. The number of neutrons is irregular, but in the heavier elements averages an increase of two from one element to the next. As many as 32 electrons may be in an inner orbit or shell; others have 18; but the innermost shell is always made up of 2 electrons; the second of 8 electrons; and never more than 8 electrons are found in the outermost shell. (For structure of typical elements see Table 1 under ATOMIC THEORY.)

The number of protons in the nucleus is always equal to the number of electrons outside the nucleus. This is the *atomic number* of the element. Isotopes have the same atomic number but differ in the composition of the nucleus. The hydrogen isotopes have been discussed. Nearly all other elements are made up of several isotopes. For example, neon always has 10 protons in its nucleus and 10 electrons in its two electron shells, there being 2 electrons in the first shell and 8 in the second. The three isotopes of neon have respectively 10, 11, and 12 neutrons in their nuclei. Assigning the value of 1 to both the proton and the neutron and neglecting the electron's weight, the atomic weight of an element made up of several types of atoms is the average weight of the different isotopes. Since there is very little of the 21 isotope, and about nine times as much of the 20 as the 22, the average weight of neon atoms is 20.2 in comparison with the standard of oxygen as 16. (See ATOMIC THEORY, Tables 2 and 3, for a list of the stable isotopes of the elements; ELECTRON THEORY.)

Symbols.—The symbol of an element is derived from the first letter or the first letter and one other letter of its name in some language. The symbols are not all derived from the English names. Sodium has the symbol Na, from the Latin word *natrium*. The Latin name for silver is *argentum* and for gold *aurum*. When more than one element begins with the same letter, a second letter is used to differentiate the symbols.

Radioactive Changes.—Radioactive disintegrations producing new and different elements involve nuclear changes. In one type of radiation a neutron appears to have broken up into a proton and electron, and the electron leaves the atom almost at the speed of light as a beta ray. To balance the additional positive charge on the nucleus, the atom adds an electron to its outermost electron shell. In a second type of radiation, 2 protons and 2 neutrons leave the nucleus as an alpha particle, which travels at about 1/10 the speed of light. The loss of

2 protons lowers the positive charge on the nucleus by 2 units, and 2 electrons are ultimately lost from the outermost electron shell. (See also RADIOACTIVITY.)

Transmutations.—Alpha particles were first used as projectiles to produce transmutation of elements by breaking up the nuclei of atoms. Protons from hydrogen and the nuclei of deuterium are driven by strong electric fields developed in a cyclotron at such high speeds that they are most effective projectiles. Neutrons released by such bombardments have very powerful effects because they are without charge and hence pass through electron shells with little difficulty. A neutron moving slowly enough to be retained in a nucleus causes profound change in the atom. Electrons travelling at nearly the speed of light and also gamma rays produce nuclear reactions.

By such bombardments it is possible to alter the nuclei of a number of elements so that other elements result. In some cases the resulting nucleus is stable, and in others the element made by the transmutation are radioactive and undergo further changes. Aside from great theoretical interest, these synthetic radioactive elements have practical value in treatment of disease and in the study of reactions in living matter. The production of plutonium from uranium with the intermediate formation of neptunium, and the chain reactions caused by capture of slow neutrons which lead to rapid fission of both plutonium and uranium 235 made possible the atomic bomb.

Valence and Chemical Combination.—Chemical reactions are now considered as being due to gain, loss, or sharing of the electrons from the outer shells of atoms. The number of atoms of an element that will combine with an atom of another element is called its *valence*. Hydrogen and chlorine have been employed for many years as valence standards. The valence of a given element is commonly defined as the number of atoms of hydrogen or of chlorine with which one atom of the element will combine or which it will displace. Thus oxygen has a valence of 2 since it combines with 2 atoms of hydrogen in water. Carbon combines with 4 atoms of chlorine and is given a valence of 4. According to the modern idea of the structure of the atom, hydrogen has one electron which enters into combinations. Chlorine has 7 electrons in its outermost electron shell and takes one more to make a stable shell of 8. Neon has 8 electrons in its outermost shell and is entirely unreactive.

A simple method of representing valence and depicting chemical reactions thereby is to allow the symbol of an element to stand for the nucleus and all of the electrons except those in the outermost shell. This part of the atom is often called the *core*. Thus oxygen has a nucleus of 6 protons and 6 neutrons, a first shell of 2 electrons, all of which constitute its core, and a second shell of 6 electrons. The outer electrons are shown as small circles beside the core, and the atom of oxygen written $\text{8}\overset{\circ}{\underset{\circ}{\text{O}}}\text{8}$. Similarly hydrogen is H[•]

sodium, Na[•]; calcium, Ca^{••}; aluminum, Al^{•••}; carbon, $\text{6}\overset{\circ}{\underset{\circ}{\text{C}}}\text{6}$; chlorine, $\text{17}\overset{\circ}{\underset{\circ}{\text{Cl}}}\text{17}$; and neon, $\text{10}\overset{\circ}{\underset{\circ}{\text{Ne}}}\text{10}$. There are two extremes in chemical combination

dors of some substances and the taste of many more are undertaken with considerable caution because of their possible poisonous character. The weight of a given volume under given conditions, otherwise called *density* or *specific gravity*, is a property of every substance. Water is the common standard of comparison of solids and liquids, while gases are generally compared with hydrogen or with air. The temperatures at which a solid melts and a liquid boils under a given pressure are physical constants that are also properties of these substances.

It is scientifically incorrect to speak of an "impure substance," and both incorrect and autological to refer to a "pure substance." In the first instance the reference is to a mixture of two or more substances. Substance means only one form of matter, and "pure" is unnecessary.

States of Matter.—Before considering chemistry further, a review of some elementary physics will be helpful. Substances and mixtures of substances, or matter in general, exist in the three states, *solid*, *liquid*, and *gaseous*. The same substance may be in any one of the three states, depending on conditions.

What is commonly thought of as a solid is a form of matter that is sufficiently hard and rigid to retain its shape independent of its surroundings. If no other force than that of gravity is brought to bear on a solid, it shows no tendency to change its dimensions. True solids are crystals that have a definite internal and external pattern, but this distinction need not be made as yet.

A liquid does not change its volume, but it takes the shape of its container. Liquids flow more or less readily, and many of them change rapidly into gases with moderate increases in their temperatures.

Gases fill any container in which they are placed, being readily compressed to smaller volumes, and expanding when pressures are lowered.

Gases at ordinary pressures are regarded as being made up of infinitely small particles called molecules. At the temperatures to which we are accustomed, these molecules are in rapid and continual motion, colliding with the walls of the container and with each other. The temperature of a gas is a measure of the intensity of the motion of its molecules. Pressure of a gas is exerted by the continued bombardment of its molecules against retaining surfaces. The space occupied by gaseous molecules and the attractions between molecules may be neglected as long as only the gaseous state is considered and pressures are not high.

In the liquid state, the molecules are still in motion, but they are so close together that attractive forces prevent the distances between them from becoming appreciable. The molecules slide freely past each other, and thus the liquid flows and there is constant mixing of molecules.

There is motion in the solid state at ordinary temperatures, but this motion is a vibration so that individual molecules do not greatly change their relative positions to each other. In fact, as will be explained later, the distinction of individual molecules is more or less lost, and still smaller units are dealt with, which necessitate chemical rather than purely physical ideas. The point at which all motion ceases is the absolute zero, which is 273 C. (460 F.) degrees

below the melting point of ice at atmospheric pressure (0° C. or 32° F.). At any temperature above absolute zero, there is some sort of motion of molecules or smaller units.

Molecules escape from the surface of a liquid, and in a closed container partially filled with liquid, the rate of escape is quickly equaled by the rate of return of the gaseous or vapor molecules to the liquid state. The higher the temperature, the more rapid is the rate of escape and of return, and the higher the pressure exerted by the molecules of the vapor. There is a similar escape and return from the surface of a solid, although for many solids the tendency is not measurably great.

When heat is applied to a solid, the vibrations of its particles increase in intensity, and at a certain point molecules escape from the surface to form a liquid. At this point the temperature does not rise further until all the solid disappears. Before this happens, if no heat is applied and its escape is prevented by insulation, there will be an equality in the number of molecules escaping or returning to the solid state, or what is known as an equilibrium.

A solution refers to a mixture of molecules of two or more substances. Ions, which are charged particles, made up of one or more atoms function like molecules in solution. Gases mix in all proportions and there are solid solutions, but the term *solution* is generally thought of as a mixture of molecules in the liquid state. Some liquids mix in all proportions, but there is usually a definite limit of the solubility of one substance in another. Solubility changes with temperature, but whether it decreases or increases depends on the nature of the substances involved.

When a membrane is interposed between a liquid that is a single substance and a solution of one substance in another, it often happens that one kind of molecule will pass through the membrane and another kind will not. For example, a solution of sugar in water divided by a membrane from water will lose water molecules from the solution. A definite pressure on the water side is required to cause the water molecules to pass at equal rates through the membrane. This *osmotic* pressure has the quantitative aspects of gas pressures. (See also **MATTER**.)

Characteristics of Chemistry.—Chemistry is primarily the science of the transformations of substances into other substances. Two or more substances may combine to form a new substance; a substance may decompose into other substances; and other changes may take place that seem more impossible and unexplainable. Iron and sulphur are substances with very marked and unmistakable properties. One is dense, gray, and insoluble, and is attracted by a magnet. The other is much less dense, is yellow, is soluble in certain solvents, and is not affected by a magnet. The two substances can be ground and mixed and then separated, either by dissolving the sulphur in carbon bisulphide or by drawing out the iron by a magnet. If the mixture is heated, it will remain hot for some time after the source of heat is withdrawn, and the product has none of the properties of iron or sulphur, but a new set of properties of its own. A red solid known as mercuric oxide is converted by heating into liquid mercury and gaseous oxygen. Metallic zinc dissolves and

disappears in a solution of sulphuric acid in water; gaseous hydrogen escapes; and removal of the water leaves a white solid called zinc sulphate. In this case two substances are converted into two other substances. These are chemical transformations. The melting of iron and its crystallization from the liquid state; the dissolving of sulphur in carbon bisulphide; the passing of an electric current in a coil around a mass of iron to render it magnetic, all are thought of as physical changes. Only when new substances are formed is the field of chemistry really entered. However, there are so many close interrelations among the sciences that it is often very hard to draw sharp distinctions.

A second striking characteristic of all chemical changes is that definite quantities are always involved. Chemical reactions take place according to fixed proportions by weight, and in the case of gases, according to simple volume ratios. For example, slightly more than 2 grams of hydrogen will combine with 16 grams of oxygen to form approximately 18 grams of water. At the same time the volume of hydrogen that combines is just twice that of oxygen. If the two substances were present in different proportions from these, some of one or the other would remain uncombined. The quantities involved have been determined with the utmost care, and the same results have been obtained a great many times, so that the law of definite proportions has been thoroughly established. This law in turn depends on the law of conservation of mass, which is that in any isolated system, or portion of the universe set aside for observation, there is neither gain nor loss of matter. This also applies to energy. A small loss in weight has been observed in connection with atomic fissions and the formation of radioactive elements. This loss in weight is accompanied by evolution of enormous quantities of energy. Instead of considering the two, mass and energy, separately, modern science puts them together in the law of the conservation of mass-energy.

A third characteristic of chemical change is that definite quantities of energy are involved. Heat energy and electrical energy are the two types that are more commonly associated with chemical reactions, although other forms such as light energy or mechanical energy also accompany chemical changes. For example, 12 grams of carbon (graphite) combine with 32 grams of oxygen to form 44 grams of carbon dioxide with the evolution of 94,030 calories of heat.

Elements.—Certain substances cannot be decomposed by any ordinary chemical methods into other and simpler substances, nor can they be made by the combination of other substances. This generalization still holds in the common experience of chemists, and any modifications of this statement will be better understood after simpler and more basic ideas have been presented. These substances that are neither decomposed nor synthesized are called *elements*. Familiar elements are oxygen, sulphur, iron, carbon, hydrogen, and 15 or 20 others, although nearly 100 elements are known. Elements combine with each other to form compounds. On the other hand, compounds may break up into elements. One element may drive another out of a compound and take its place. Two compounds may exchange elements to form new compounds. A certain group of elements may

remain together through chemical changes while other elements in the compound are exchanged or replaced. Such groups are called *radicals*.

Two elements may combine in several different ways to form different compounds. However, it is a striking fact that in such cases, if the quantity of one element in these several compounds is fixed at a certain value, the quantities of the second element in these compounds bear a very simple relationship to each other. For example, 28 grams of nitrogen will combine with 16, 32, 48, 64, and 80 grams of oxygen to form 5 different compounds. There are respectively 2, 3, 4, and 5 times as much oxygen as in the first compound.

Thus it is possible to assign a numerical value to each element that will represent the quantity that will combine with another element. Thus if the value of 16 is given to oxygen, either 16 grams or some simple multiple of 16 represents the combining proportions of oxygen in all of its compounds. (See also ELEMENT.)

Atomic Theory.—These remarkable quantitative relationships characteristic of chemical changes are satisfactorily explained by the atomic theory (q.v.), first proposed by John Dalton early in the 19th century and modified more than one hundred years later by other fundamental discoveries. In its simplest terms, this theory may be stated as follows: The elements are made up of exceedingly small particles called atoms that are incapable of further subdivision. The word *atom* means indivisible. Incidentally, the idea of a limit to the subdivision of matter went back to the ancient Greek philosophers, but was without experimental proof. The atoms of one element are all exactly alike, but are different from the atoms of all other elements. Chemical reactions are between one atom of one element and one atom of another element or between very small numbers of each. This accounts for the simple multiple proportions just discussed. If all atoms of iron have the same weight and this is true of the atoms of sulphur, and if one atom of iron combines with one atom of sulphur to form iron sulphide, then the same weight relations would hold good if a billion billion atoms of iron combined with a like number of sulphur atoms. Also, if 1 atom of oxygen combined one instance with 1 atom of copper and another with 2 atoms of copper, the relation between the weights of copper in the two compounds would be the simple ratio of 1 to 2. Atomic theory has had to be modified to a certain extent by the discovery that the atoms of an element are not all alike in weight. What is now called an element is a form of matter of whose atoms have the same atomic number, that is, the same number of protons in the nucleus and the same number and arrangement of electrons outside the nucleus. These different forms of the same element are called *isotopes*. However, the isotopes of each element are so thoroughly mixed that a very precise value can be assigned to represent their average weight, and this is the value that is commonly given as the atomic weight of an element. This will be discussed more fully as individual elements are taken up. (See page 407b.)

Those values chosen to represent the weights of the atoms of the elements on the basis of a great many analyses of compounds have been further confirmed by an obse

chemical reactions without themselves being changed are called *catalysts*. The effect of a catalyst is exactly the same on the two opposing reactions in a chemical equilibrium. Substances that function as catalysts are generally characterized by possessing large and active surfaces on which the reacting materials are attracted. Notable examples of catalysis are the effects of finely divided platinum on the oxidation of sulphur dioxide, of spongy iron containing small amounts of other elements on the combination of nitrogen and hydrogen, and of powdered manganese dioxide on the decomposition of potassium chlorate.

Ionization.—Reference has been made to that type of chemical combination in which electrons are completely transferred from one atom to another. Such substances, when dissolved in water, break up into charged particles known as *ions*, and this process of dissociation is called *ionization*. The water appears to insulate the ions from each other so that they can maintain a separate existence and function just as molecules in a solution. Water molecules also tend to combine with ions by virtue of either one of the pairs of unshared electrons which each water molecule has. A water molecule, for instance, will capture a proton, or the hydrogen nucleus, and with it form a complex

Those substances in which electron transfer is complete and also those which permit the removal of an atom or group of atoms by water are regarded as being completely ionized in solution. Their solutions readily conduct an electric current by this mechanism, as illustrated by copper chloride, CuCl_2 . This substance ionizes into copper ions, Cu^{++} and 2 chloride ions, Cl^- . If 2 electrodes of inert material that dip into a copper chloride solution are connected to a source of current such as a dynamo or battery, which may be thought of as an *electron pump*, electrons will be drawn out of one electrode and forced into the other. The deficiency of electrons in one and excess in the other is not great, but as soon as copper ions come in contact with the negative electrode, which has an excess of electrons, each copper ion will take 2 electrons ($\text{Cu}^{++} + 2 \ominus \rightarrow \text{Cu}^0$). At the same time 2 chloride ions will lose an electron each to the positive electrode and become chlorine molecules ($2 \text{Cl}^- \rightarrow \text{Cl}_2 + 2 \ominus$). The symbol \ominus indicates a free electron. The zero is the symbol of an element indicates that the element is neutral, or that it is without the excess of electrons indicated by a minus sign or above the symbol or without deficiency of electrons indicated similarly by plus signs. As copper metal is formed and deposited, the chloride ions will attract other copper ions. In the same way copper ions around the negative electrode will attract chloride ions. As long as there are any amounts of these two kinds of ions in solution, there will be a steady migration of ions, and a current will flow.

The fact that the quantity of electricity flows through a solution of an ionized compound is not as much as should be carried, on the basis of the number, charge, and speed of the ions was once interpreted as meaning that there is an equilibrium between the portion of the

compound that was not dissociated and the ions. Unless the discrepancy is very great, indicating only slight dissociation, the difference is explained by attractions between ions that slow down their movements and lessen the quantity of current.

Acids, Bases, Salts.—Those substances that ionize readily are grouped into three classes: acids, bases, and salts. The older definition of an *acid* is a substance that contains one or more atoms of hydrogen that become hydrogen ions in solution. Now it is generally agreed that free protons do not exist in solution. Water or some other substance must combine with the proton to form what is still often written H^+ , but which should be H_3O^+ or some other group of a similar nature. Hence acids are proton donors. A *base* is still very commonly thought of as a substance containing one or more hydroxyl (OH) groups that would give hydroxyl ions (OH^-) in solution. According to the more modern idea, hydroxyl and many other groups or even neutral compounds are bases because they accept protons. The hydrogen of an acid and the hydroxyl of a base combine readily to form water, which ionizes to the extent of only a few molecules out of every billion. The older way of expressing the reaction was $\text{H}^+ + \text{OH}^- \rightarrow \text{H}_2\text{O}$. The more modern way is $\text{H}_3\text{O}^+ + \text{OH}^- \rightarrow \text{H}_2\text{O} + \text{H}_2\text{O}$. *Salts* are made up of the same positive ions that are present in bases and the same negative ions that are in acids. Thus H_2SO_4 is sulphuric acid and $\text{Ca}(\text{OH})_2$ is calcium hydroxide, a base, while CaSO_4 is calcium sulphate, a salt. Most salts ionize completely. Even those that dissolve in water to a very slight extent are represented in the liquid phase solely by ions.

If a solution of sodium chloride, which is essentially a solution of sodium ions (Na^+) and chloride ions (Cl^-), is mixed with a solution of potassium nitrate containing potassium ions (K^+) and nitrate ions (NO_3^-), no reaction will take place. It is necessary that a substance be formed that is either not ionized or that is insoluble. If equimolecular quantities of an acid and a base, each in solution, are mixed, the hydrogen and hydroxyl ions will form water, heat will be evolved as an evidence of reaction, and the other two kinds of ions will remain as they were.

In the same way mixtures of a solution of silver nitrate and sodium chloride will result in the formation of insoluble silver chloride, and only sodium ions and nitrate ions will remain in solution.

Ionic Equilibria.—Many substances, especially compounds of carbon, show no evidence of appreciable ionization. Others, however, undergo a small but entirely measurable degree of ionization. These include mainly what are called *weak acids* and *weak bases*. Boric acid, H_3BO_3 , ionizes so slightly that a solution of it may be applied to the eye without injury. Even very dilute hydrochloric acid (HCl), will cause intense pain to the eye surface. It is certainly not an effect of the chloride ion, since a solution of sodium chloride contains chloride (Cl^-) ion and causes no pain. The difference is in the concentration of the hydrogen ions. Because of its familiarity this may still be written $[\text{H}^+]$ although $[\text{H}_3\text{O}^+]$ is understood.

In the case of weak acids and weak bases, there is a definite equilibrium between the compound and its ions. The product of the concen-

tration of the ions divided by the concentration of the unchanged compound is a constant value at a given temperature and is given the name *ionisation constant*.

Another striking fact is that in saturated solutions of very slightly soluble substances, the product of the concentrations of the ions present is a constant at a given temperature. Variations from this principle are due to interionic attractions, which are very slight with the small number of ions furnished by the more insoluble substances. The concentrations of the two types of ions may be very different and still the product is a constant. This *solubility product* principle is the basis of an important part of quantitative analysis. With it is coupled the concept of ionization constants. Thus, ammonium hydroxide in water solution dissociates slightly into ammonium ions (NH_4^+) and hydroxyl ions (OH^-). If considerable quantities of ammonium ions are added from an ammonium salt, the hydroxyl ion concentration is greatly suppressed, since it must change to compensate for the increase of the concentration of the other kind of ion. The concentration of the ammonium hydroxide cannot change much since it already represents most of what is in solution. Concentrations are expressed by inclosing symbols and formulas in brackets.

$$\frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3][\text{H}_2\text{O}]} = A \text{ constant.}$$

If a magnesium salt is added to a solution of ammonium hydroxide, insoluble magnesium hydroxide, $\text{Mg}(\text{OH})_2$, will be formed. If there is an excess of ammonium ions, there will be so few hydroxyl ions that the solubility product value of magnesium hydroxide is not reached and no precipitation takes place. Hydrogen sulphide in water solution is hydrosulphuric acid, and is a very weak acid. Many sulphides are quite insoluble. By employing varying amounts of other acids as a source of hydrogen ions and other substances that will act similarly, it is possible to separate, detect, and estimate a number of metals that form comparatively insoluble sulphides.

The solubility product principle represents an ideal solution. The actual concentrations should be corrected by factors in order to obtain the effective concentrations or activities of the ions involved. Some authors prefer to use the term activity product rather than solubility product. With these modifications the principle has wide applications both in chemical analysis and in manufacturing operations.

Electromotive Force.—The tendency of ions or of elements to gain or lose electrons may be measured as an electromotive force. Reactions involving electron transfers are also a commercial source of electric current. When zinc and bromine are brought into contact with each other, they combine with the evolution of heat and the reaction is written as $\text{Zn} + \text{Br}_2 \rightarrow \text{ZnBr}_2 + \text{heat}$. If metallic zinc as an electrode is in contact with a solution of zinc ions, and bromine is dissolved in a bromide solution in which there dips an inert electrode, and if the two solutions are connected by a column of liquid in which a salt is dissolved, and the electrodes are connected through electrical measuring equipment, a current will flow but no heat will be developed. The quantity of current will be proportional to the quantity of zinc and bromine used up just as the quantity of

heat is similarly proportional to the amount of each that has reacted in the case of ordinary combination. Exactly the same shift of electrons takes place, but instead of direct transfer, the electrons pass through a wire and are measured with instruments. The ion reactions are: $\text{Zn}^0 \rightarrow \text{Zn}^{++} + 2 \ominus$, and $\text{Br}_2 + 2 \ominus \rightarrow 2 \text{Br}^-$. Each reaction takes place entirely separate and apart from the other, and the reacting substances may never come in contact with each other.

The intensity of the reaction or the extent of the driving force, as electrons are gained or lost, is measured in volts, and the combined effect, together with quantities of materials that react, will determine the energy of the reaction. The electrical energy produced by two half cells, when the reactants are separated, is exactly the same as the heat energy produced when the reactants are in contact, if the same quantities are used up in each case.

Other types of reactions whose electromotive force may be measured are displacements and changes in valence. The tendency to gain or lose electrons is also a function of the concentration of the ions in a solution. Although the difference between the electromotive forces of two solutions of different concentrations of the same substance is not great, it may be measured readily and used as a method of analysis. The hydrogen ion concentration of a solution is often very important, and delicate instruments employing electronic tubes compare the unknown solution with a solution of known hydrogen ion concentration by measuring the electromotive force difference of the two solutions.

An important type of reaction is referred to as an *oxidation-reduction* reaction. Many of these can be carried out in cells as a source of current, so that the potentials or driving forces of each element or ion may be measured. Others can be described and explained on the same basis of electron transfer, even though electrical measurements cannot be made. The term *oxidation* originally meant combination with oxygen and *reduction* removal of oxygen, but similar reactions involve no oxygen. The terms now mean loss of electrons in oxidation and gain of electrons in reduction. The combination of zinc and bromine, involving no oxygen, was an oxidation-reduction reaction.

One of the oldest types of galvanic cell for production of an electric current was made up of zinc and copper dipping into a solution of copper sulphate. The electrode reactions were $\text{Zn}^0 \rightarrow \text{Zn}^{++} + 2 \ominus$, and $\text{Cu}^{++} + 2 \ominus \rightarrow \text{Cu}^0$. Zinc dissolved, copper plated out, while the sulphate ion (SO_4^{--}) remained unchanged. The modern dry cell is essentially a zinc-hydrogen cell. The source of hydrogen is the ammonium ion of ammonium chloride. Hydrogen does not escape because it is made to combine with the oxygen of manganese dioxide. Ammonia forms a complex compound with zinc chloride and remains. The cell is not dry, the solution being either in the form of a jelly or held by absorbent materials so that no liquid flows.

While many cells cannot be restored to their original condition and are thus called *primary cells*, there is an important place in the practical field for a type of cell in which the products of the reaction that produced the current can be converted by a reversal of the original reaction to the starting substances. The economy of these *secondary cells* lies in their portability and the

utility of small units that can be recharged when they are not in use. The lead-sulphuric acid storage battery is explained by this reversible reaction.

$\text{Pb} + \text{PbO}_2 + 2 \text{H}_2\text{SO}_4 \rightleftharpoons 2 \text{PbSO}_4 + 2 \text{H}_2\text{O}$. The electrode reactions are $\text{Pb}^0 \rightleftharpoons \text{Pb}^{++} + 2 \text{e}^-$, and $\text{Pb}^{++++} + 2 \text{e}^- \rightleftharpoons \text{Pb}^{++}$. The electrodes are lead grids containing at first spongy lead at the negative and lead dioxide at the positive. The electrolyte is a water solution of sulphuric acid containing about 30 per cent of this acid. When the grid material of both electrodes has been changed to lead sulphate, in which the lead atoms are minus 2 electrons (Pb^{++}), the battery is recharged by the passage of a current and the neutral lead and the lead minus 4 electrons (Pb^{++++}) of the lead dioxide are restored. The nickel-iron battery depends on the shift of electrons of this type: $\text{Fe}^0 \rightleftharpoons \text{Fe}^{++} + 2 \text{e}^-$, and $\text{Ni}^{+++} + 2 \text{e}^- \rightleftharpoons \text{Ni}^{++}$. See also ELECTROCHEMISTRY; ELECTROLYSIS.

Periodic System.—The elements may be classified and arranged according to their properties in what is known as the periodic system. This is more fully discussed in another volume. (See PERIODIC LAW). Briefly, the principle is expressed in the periodic law which states that "the properties of the elements are periodic functions of their atomic weights." When the elements are arranged in ascending order of their atomic weights, there is a regular or periodic recurrence of certain properties so that elements may be arranged in groups or families. Active metals, which are electropositive elements, are grouped together, and likewise active nonmetals or electronegative elements fall into separate groups. This principle has been of great value in leading to the discovery of new elements as well as to decisions as to the correct atomic weight and valence of others that have long been known. There were, however, several defects and discrepancies that could not be cleared up as long as the determining factor was atomic weight.

The modern periodic system shifts the emphasis to atomic number. It is therefore necessary to amend the periodic law thus: "The properties of the elements are periodic functions of their atomic numbers." It will be remembered that the atomic number of an element is the number of protons in its nucleus, which is also the number of electrons in shells or orbits around the nucleus. The electrons in the outermost shell are involved in chemical reactions, but the positive nucleus has a great influence on the reactivity of an element. By making this change, the difficulties of the older system vanish. These elements that are alike have the same types of electron shells as far as the outermost and next innermost shells are concerned. Thus sodium and potassium each have one electron in the outermost shell and 8 in the next underlying shell. The "rare earth" elements, which found no place in the old periodic system, are regarded as being alike in all respects except one electron shell and, of course, increasing size of nucleus. Each has the same number of electrons in the outermost or valence shell and hence they are very much alike. The fact that argon atoms on an average are heavier than potassium atoms, and tellurium atoms heavier than iodine atoms, while their positions are reversed in the old periodic system because of their properties, has no meaning under the new system. Potassium has an atomic number of 19 and argon of only 18,

while iodine's atomic number is 53 and that of tellurium is 52. The original discrepancy was due to the heavy isotopes of some of these elements.

Elements Found in Nature.—Since a number of new elements have been produced by the impact of various particles such as neutrons, hydrogen, deuterium, and helium nuclei as previously described, and since the isotopic composition of such elements varies with the method of production, the International Union of Pure and Applied Chemistry has voted not to include the atomic weights of these elements in their next official table. The most recent table approved by this organization is given above. It is probable that the value for Beryllium will be changed to 9.013.

The International Union of Pure and Applied Chemistry in 1949 adopted certain changes in official names, only three of which affect the above table. The spelling of "lutecium" is changed to "lutetium." The element given above as "Columbium" is to be known as "Niobium," a term common in England. The change which will require considerable time for Americans and English to adopt is "Wolfram" instead of "Tungsten."

Elements Artificially Produced.—The products of nuclear reactions include a large number of isotopes of elements found in nature and listed in the foregoing table. Following are elements whose existence in nature is not considered probable and which have been produced by the bombardment of nuclei of other elements by various particles.

Atomic number	Name	Symbol
43	Technetium	Tc
61	Promethium	Pm
85	Astatine	At
87	Francium	Fr
93	Neptunium	Np
94	Plutonium	Pu
95	Americium	Am
96	Curium	Cm

In 1949 Dr. Glen T. Seaborg and co-workers announced the production of Element No. 97 and early in 1950 of Element No. 98, and have proposed the names of Berkelium and Californium respectively for these two elements. Neptunium appears to be the first of a new series of elements resembling the "rare earth series."

Typical Elements.—A few typical groups will be discussed and some of the compounds of a few elements will be described.

What was thought to be nitrogen, when the other gases of the air had been removed, proved to be a mixture containing mainly nitrogen but also enough argon to constitute nearly 1 per cent of the air. This discovery was closely paralleled by finding a gas in very small amounts in the air and later in considerably larger amounts in natural gas whose spectrum was identical with a component of the sun. This element was named helium. The two representatives of a group necessitated the finding of other elements having the same properties, which led to the isolation of neon, krypton, and xenon from the air. The gas, radon, formed when radium disintegrates, was found to belong to this same group, and all the gaps in this group of the periodic table were thus filled. All of these gases but helium have 8 electrons in their outermost shell. Helium has only 2, but this arrangement next to the nucleus is also known to be very stable. None of these elements form compounds with other elements.

Hydrogen belongs to Group 1A and Period 1, being made up of a single proton as a nucleus

and a single orbital electron. The more common isotope, deuterium, has a nucleus of one proton and one neutron, but like hydrogen a single orbital electron. An atom of hydrogen may serve as a link between strongly electronegative atoms such as oxygen, nitrogen, and fluorine, the bond being weaker than a co-valent bond. The binding of water molecules together in this way accounts for some of the unique physical properties of this substance.

Lithium, sodium, potassium, rubidium, and cesium, each have one electron in their outer shells under which is a stable shell of 8 electrons, or in the lithium atom the stable innermost shell of 2 electrons. These elements are all electropositive, each losing their one valence electron in combining with other elements. Thus they all have a positive valence of 1. Their activity increases with increasing atomic weight, since the farther away the one valence electron is from the positive nucleus the more easily it is lost. All of these are metals, but their great chemical reactivity prevents their existence in the uncombined state unless they are protected from air and moisture. The salts of sodium and potassium are particularly important. Sodium chloride is a very abundant and useful compound. Their hydroxyl compounds are bases such as NaOH and KOH. Their oxides are called basic oxides, since they react with water to form bases. $\text{Na}_2\text{O} + \text{H}_2\text{O} \rightarrow 2\text{NaOH}$.

At the other side of the periodic table is the halogen family, fluorine, chlorine, bromine, and iodine. Each has 7 electrons in the outermost shell above cores that are like the complete atoms of helium, neon, argon, and krypton with respect to completed electron shells. It will be remembered that a core is the entire atom except the outer electron shell. In combining with most elements the halogens gain 1 electron to complete a shell of 8 electrons. The smaller the number of electron shells, the more active is the element, since the positive nucleus is nearer and attracts the single electron most strongly. Typical halides are: calcium fluoride, CaF_2 ; aluminum chloride, AlCl_3 ; potassium bromide, KBr ; and sodium iodide, NaI . The halogens except fluorine may lose one or more of their outside electrons to such a powerful electronegative element as oxygen. In this type of reaction, electrons are most easily lost from the element whose outer electrons are most distant from the positive nucleus. Chlorine liberates iodine from iodides, but iodine liberates chlorine from chlorates. Examples of compounds in which the halogen loses electrons are: chlorine monoxide, Cl_2O^+ ; chlorine dioxide, Cl_2O_2^+ ; sodium chlorate, $\text{Na}^+\text{ClO}_3^-$; and chlorine heptoxide, Cl_2O_7^+ . In so representing the positive or negative valences of atoms in compounds, it is not implied that the electrons are completely lost or gained or that the elements in these compounds form ions alone. It merely indicates that the element has lost or gained some of its electrons sufficiently to justify this method of marking its charge.

Oxygen is the most abundant of the elements in the earth's surface. It has 6 electrons in its outer shell and practically always acquires 2 electrons from other elements in combination. It is thus a powerful electronegative element. Oxygen alone does not form an ion in any measurable quantity. It is present in many negative ions such as hydroxyl, OH^- , Sulphate, SO_4^{2-} , nitrate, NO_3^- and phosphate, PO_4^{3-} . It combines

th most other elements. Sulphur resembles oxygen in having 6 electrons in its outer shell. Like the halogens it attracts enough electrons to make a shell of 8, but it also loses its electrons to very active negative elements. Typical sulphur compounds are the sulphides such as hydrogen sulphide, $\text{H}_2\text{S}^\ominus$, and copper sulphide, $\text{Cu}^\oplus\text{S}^\ominus$, and the acid oxides, $\text{S}^\oplus_4\text{O}_6^\ominus$ and $\text{S}^\oplus_6\text{O}_8^\ominus$ and their corresponding acids, sulphurous acid, $\text{H}_2\text{S}^\oplus_3\text{O}_3^\ominus$ and sulphuric acid, $\text{H}_2\text{S}^\oplus_4\text{O}_4^\ominus$.

Nitrogen has 5 electrons in its outer shell, it is the element, occurring as a gas whose molecule is made up of two atoms, N_2 , is extremely stable under rather severe conditions. Nitrogen takes up 3 electrons from 3 atoms of hydrogen to form ammonia, NH_3 , but loses one or more of its electrons in forming its oxides and oxyacids. The two most important nitrogen compounds containing oxygen are nitric oxide, NO^\ominus , and nitric acid, $\text{H}^\oplus\text{N}^\oplus\text{O}_3^\ominus$. Phosphorus, arsenic, antimony, and bismuth belong to the same family and form somewhat similar compounds. Antimony and bismuth have the physical properties of metals but their salts are not so stable in water as those of the more active metals, and even bismuth is associated with oxygen in negative ions.

Some metals such as chromium and manganese behave in their lower valences like the other metals. That is when they lose only 2 or 3 electrons, for example, they form positive ions. When a chromium atom loses all of its 6 electrons, its oxide, $\text{Cr}^\oplus_6\text{O}_4^\ominus$ is much like sulphur dioxide, $\text{S}^\oplus_2\text{O}_2^\ominus$. Both react with water to form strong acids. Manganese resembles chlorine in the oxide, $\text{Mn}^\oplus_2\text{O}_7^\ominus$ and in permanganic acid, $\text{H}^\oplus\text{Mn}^\oplus\text{O}_4^\ominus$.

Carbon is a most remarkable element because of the varied nature of its compounds and their enormous number. Several times as many carbon compounds are known as those of all the other elements put together, and an infinite number are theoretically and structurally possible. Carbon has 4 electrons in its outer shell. It combines by sharing these electrons with those of other elements so that it is surrounded by a shell of 8 electrons. For example, a compound with hydrogen may be represented thus:

These may be written $\text{C}^\oplus_4\text{H}_{10}^\ominus$ and $\text{C}^\oplus_4\text{H}_8^\ominus$, but only when changes of valence are necessary to account for reactions. The sharing of electrons does not leave any atom strongly charged positively or negatively in most carbon compounds. The pair of bonding electrons in carbon compounds is more conveniently represented by a single line called a bond. If there are two or three pairs of electrons joining 2 carbon atoms or a carbon atom with another atom such as oxygen or nitrogen, two or three lines are employed.

Carbon has the remarkable property of combining with itself to build up rings and chains, some of the latter being of great length and complexity. The large number of carbon compounds is mainly due to the different ways in which carbon and other atoms are linked to-

gether. Thus, there are two different carbon-hydrogen compounds that are made up of the same number of atoms of each element. The

have markedly different physical properties and react somewhat differently. Ethyl alco-

Another cause of difference is due to different geometrical structures of compounds which have the same linkage of atoms. If four different substituents are attached to a carbon atom, two structures are possible, one being the mirror image of the other. The two structures are like a right hand and a left hand. Crystals and solutions of such unsymmetrical substances turn the plane of polarized light either to the right or the left, and are called *optically active* compounds.

Those compounds in which carbon atoms are linked together in straight or branching chains, and in which the maximum valence of 4 for carbon is always realized are called *aliphatic* compounds. Those compounds in which all the valences of carbon are not satisfied are referred to as *unsaturated*. A single line represents a pair of electrons, while two and three parallel lines indicate two and three electron pairs between atoms. Rings of six carbons in which each carbon apparently has the valence of 3 are known as *aromatic* compounds. Heterocyclic compounds are characterized by oxygen, sulphur or nitrogen atoms in rings.

For purposes of simplification all other compounds may be regarded as derived from hydrocarbons (made up only of carbon and hydrogen) by the replacement of one or more atoms of hydrogen by other elements or groups. Following are some common types of monosubstituted derivatives. In these the symbol R represents any hydrocarbon from which one hydrogen has been removed. ($-\text{CH}_3$ is methyl or methane less one hydrogen; and $-\text{C}_2\text{H}_5$ is ethyl from ethane.) $\text{R}-\text{OH}$, Alcohols; $\text{R}-\text{Cl}$, Alkyl chlorides; $\text{R}-\text{O}-\text{R}'$, Ethers; $\text{RH}(\text{C}=\text{O})$, Aldehydes; $\text{R}-(\text{C}=\text{O})\text{R}'$, Ketones; RCO_2H , Acids; $\text{RCO}_2\text{R}'$, Esters; $(\text{R}-\text{CO})_2\text{O}$, Anhydrides; RCONH_2 , Amides; RCOCl , Acid Chlorides; RNH_2 , R_2NH , and R_3N , Amines; RNO_2 , Nitro Compounds; RSO_3H , Sulphonic Acids.

The symbol  represents benzene, or C_6H_6 .

Several of these rings may be linked together with or without the sharing of carbons.

Many carbon compounds of infinite complexity such as rubber, cellulose, and protein may be broken up into units of relative simplicity. This tendency of many similar or identical units to

join together is peculiarly characteristic of carbon compounds.

Until well into the 19th century, carbon compounds were considered as entirely the product of some sort of life process, and the whole field of carbon chemistry was called organic chemistry. The term still remains in use, but the synthesis of many substances changed its meaning to the "chemistry of carbon compounds." In addition to all manner of products of animal and vegetable growth and of such fossil remains as coal, natural gas, and petroleum, a vast number of carbon compounds have been synthesized from simple sources.

Aliphatic and alicyclic hydrocarbons are found in nature primarily in petroleum and natural gas. A number of such hydrocarbons have been synthesized, but only when such syntheses added to the knowledge of chemical theory or when substances of special properties were needed. Those hydrocarbons in this class in which all four valences of the individual carbons are fully satisfied are relatively unreactive, and comparatively little use of these hydrocarbons was made as the original source of other substances until their abundance and further knowledge have made them more attractive as synthetic reagents. On the other hand, unsaturated hydrocarbons containing one or more double or triple bonds, that is two or three pairs of electrons, are quite reactive, and either add elements or groups or combine with each other to satisfy the condition of chemical saturation. Halogens, halogen acids, and other acids, such as sulphuric acid, add to unsaturated compounds most readily. For example, sulphuric acid adds to the simple olefin, ethylene, CH_2CH_2 , to form ethyl hydrogen sulphate, $\text{CH}_3\text{CH}_2\text{HSO}_4$, which is readily hydrolyzed to produce ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}$, identical with "grain alcohol" resulting from the fermentation of sugar. The addition of a saturated to an unsaturated hydrocarbon, both of low molecular weight, is the basis of the "alkylation" process for making particularly efficient motor fuels. The combination of a number of molecules of the same unsaturated compound is the basis of the production of most modern plastics.

In those substances in which there is a ring of six carbons with three alternate double bonds, referred to above, the arrangement of binding electrons is such that there is not the same type of reactivity as in ordinary unsaturated hydrocarbons, and the reactions and compounds containing the "benzene ring" have appeared sufficiently different to chemists to justify a separate class of substances which are referred to as "aromatic" hydrocarbons. Modern theories, however, account for these differences so that all hydrocarbons can be considered together.

Although the direct action of an active halogen such as chlorine on an aliphatic hydrocarbon is a practical and commercial method for introducing an alkyl group into a compound, it is more common to begin with an alcohol in which the hydroxyl group (OH) replaces one of the hydrogens of the hydrocarbon. A number of the simpler alcohols are products of fermentation, notably ethanol or ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}$. The simplest alcohol, methanol, CH_3OH , is readily made by the action of hydrogen on carbon monoxide at high pressure in the presence of a catalyst, and is also one of the products of the heating of wood in the absence of air. Other alcohols, notably those in which the carbon to which the

hydroxyl group is attached is linked to two or three other carbon atoms instead of one, are obtained from unsaturated hydrocarbons. Petroleum hydrocarbons are now being oxidized directly to form a variety of compounds. Alcohols are quite reactive and are the sources of most of the substances whose formulas were given in an earlier paragraph.

The term "carbohydrate" refers to a class of compounds made up of oxygen, hydrogen, and carbon, in which there are twice as many hydrogen as oxygen atoms. These were considered in the earlier years of organic chemistry as "hydrates" of carbon. They are now regarded as ring compounds with an oxygen atom taking the place of a carbon atom in the ring, and with hydrogen and hydroxyl groups attached to the carbon atoms. The simpler carbohydrates, whose structures are reasonably well known, are the sugars. More complex carbohydrates, in which a number of rings are linked together, include dextrin, starch, and cellulose. Such cellulose derivatives as nitrocellulose, cellulose acetate, and rayon are the results of reactions involving the hydroxyl groups, and are similar in their method of formation to the derivatives of the simpler alcohols.

Natural fats, oils, and waxes, both of animal and vegetable origin, are for the most part derivatives of acids, esters in which both glycerin, a trihydroxyl alcohol and monohydroxy alcohols are combined with fatty acids. A large part of this class of substances are foods, such as butter fat, lard, olive oil, soybean oil, and cottonseed oil. Breaking up of the esters results in soaps, fatty acids, and glycerin as commercial products.

An important class of substances, the proteins, are used both as foods and in commerce in the form of casein plastics, gelatin, and leather. Proteins are regarded as made up of one or more of the 24 naturally occurring amino acids by the elimination of water between the individual molecules by life processes. Substances analogous to the partial decomposition products of proteins in which the molecules are split and water is added have been synthesized. In the processes of metabolism, food proteins are broken down and the amino acids recombined to form the particular proteins of the body.

Still more complex substances such as dyes, plastics, and pharmaceuticals are the results of organic syntheses, in which relatively simple substances are progressively combined. On the other hand, natural products such as vitamins, hormones, and enzymes have been broken down so as to indicate their structures, and some have been synthesized. The whole field of carbon compounds is being explored with increasing thoroughness.

Silicon has the same outer electron shell as carbon, $\cdot\text{Si}\cdot$. Compounds of silicon are present

in clay, shale, and rocks of every sort except such materials as limestone and marble. This element resembles carbon in many ways, but forms relatively a much smaller number of compounds. Its hydrogen compounds are not stable and its atoms do not combine with each other as do carbon atoms. It is found mainly in combination with oxygen as SiO_2 and in silicates or salts of oxygen acids of silicon.

Colloids.—While almost any substance may exist in what is called the *colloidal state*, it is

so common in the field of carbon and silicon compounds that the topic may properly be introduced at this point. A colloidal *sol* refers to a dispersion of very small particles in a fluid medium of some sort. These particles contain many molecules, but their surfaces are so large in proportion to their masses that surface forces assume great importance. Colloidal particles are small enough to be deflected by the impact of molecules. They are also electrically charged, probably by having charged atoms or groups of atoms attached to them. For these reasons the particles remain dispersed in a fluid for an infinitely long time, whereas larger particles will ultimately settle. A colloidal jelly is made up of particles that attract and hold large amounts of solvent. When the solvent is driven out the remaining porous and quite rigid solid is known as a *gel*. Surfaces, particularly those which are greatly enlarged because of microscopically fine pores, are capable of attracting and holding other substances, a phenomenon known as *adsorption*.

Metals.—The salts of the metals of other groups behave in much the same way as those of the active metals. Many occur in natural deposits along with the oxides of these metals. The metals themselves, particularly those that have great mechanical strength, high electrical conductivity, and other desirable physical properties, are liberated from their compounds for industrial use. Some metals are deposited either from water solutions of their compounds or from molten salts by the use of the electric current. Still larger quantities are obtained as the free elements by removing other elements from their compounds under the influence of high temperatures. Carbon and carbon monoxide, CO, are the chief substances by which oxygen is commonly removed from metals. These procedures are discussed in other articles. See also ELECTRO-CHEMISTRY.

Divisions of Chemistry.—The science of chemistry is divided more or less arbitrarily into a variety of fields. The lines between them are often far from sharp. One major division is between carbon and its compounds and all other elements and their compounds. These two fields are still erroneously called organic chemistry and inorganic chemistry. The detection and determination of the quantities of elements and groups of elements as ions or compounds is the subject matter of analytical chemistry, which is further subdivided into qualitative analysis and quantitative analysis, depending on whether identification or measurement of quantity is involved. The terms biological, physiological, electrochemical, and metallurgical chemistry are largely self-explanatory. Physical chemistry refers primarily to a study of fundamental theories and principles with the help of the techniques and methods of the physicist. The major divisions of these five fields have been published by the National Roster of Scientific and Specialized Personnel with the advice of leading chemists specializing in each of these fields, and are as follows:

Physical Chemistry.—Thermodynamics and thermochemistry. Chemical kinetics (homogeneous and heterogeneous systems, catalysis, tracers). Chemical equilibria (homogeneous and heterogeneous equilibria, phase rule, alloys). Structure of gases, liquids, and solids (crystallography, the metallic state, X-ray and electron diffraction). Atomic and nuclear structure (isotopes, atomic fission, valence). Colloids and surface phenomena. Solutions (aqueous and nonaqueous, electromotive force,

ionic equilibria, conductance, diffusion, viscosity). Photochemistry (Raman spectra, infrared spectra, spectroscopy, effect of light on chemical reactions).

Theoretical physical chemistry (applications of quantum theory, statistical mechanics, physical applications of organic chemistry). Miscellaneous fields (polymers and polymerization, biophysical chemistry, low temperature phenomena).

Analytical Chemistry.—Qualitative analysis. Quantitative analysis (determination and measurement of properties by common methods, and separation of substances by volatilization, precipitation, extraction, and electro-deposition).

Special instrumental methods (polarizing microscope, refractometer, polariscope, turbidimeter, nephelometer, colorimeter, spectrograph, spectrophotometer, mass spectrograph and spectrophotometer, X-ray and electron diffraction equipment, potentiometer, polarograph, photoelectric cell, colorimeter, pyrometer, molecular still).

Microanalytical methods.

Analytical chemistry is also often divided according to the types of substances analyzed such as metals, oils and fats, foods, etc.

Inorganic Chemistry.—Mineral acids and their salts. Oxides, hydroxides, and hydrous oxides of metals.

Nonmetals and their compounds.

Iron and iron alloys.

Nonferrous metals and alloys.

Rare elements.

Radioactive elements.

Organic Chemistry.—Aliphatic and alicyclic compounds.

Aromatic and polynuclear hydrocarbons.

Alcohols, aldehydes, ketones, ethers, acids and acid derivatives.

Carbohydrates (sugars, starch, cellulose).

Organometallic compounds.

Organic compounds containing sulphur, halogens, phosphorus and other nonmetals.

Heterocyclic compounds (purines, quinolines, alkaloids).

Nonheterocyclic nitrogen compounds (nitro, diazo, amino derivatives, amino acids, proteins).

Miscellaneous organic compounds.

Biochemistry.—Physiological chemistry (animal).

Agricultural chemistry.

Foods, composition and processing.

Nutritional biochemistry.

Enzymes and microorganisms (fermentation, moulds, water, sewage, sanitation).

Pharmaceutical chemistry.

Toxicology.

Chemical Adviser, General Staff, Department of the Army; Former Dean, School of Chemistry, Rutgers University.

CHEMITYPE, a term used in engraving to include various relief processes by which a drawing or impression from an engraved plate may be produced in relief to fit it for printing on an ordinary printing press. One of these, devised by C. Pül in 1843, depends on filling up the lines of the engraved zinc plate with some metal or alloy, and etching away the zinc.

CHEMNITZ, or **KEMNITZ**, Martin, German Protestant theologian: b. Treuenbrietzen, Brandenburg, Nov. 9, 1522; d. Brunswick, April 8, 1586. He received his early education at Magdeburg and Frankfurt on Oder, and later studied at Wittenberg. A follower of Melancthon, he wrote *Loci Theologici* (1591), a valuable commentary on Melancthon's system of dogmatics. Later he embraced the Lutheran doctrines and did much to spread them among Saxon and Swabian churches. In 1562 he attacked the

Jesuits in his *Theologiae Jesuitarum Praecipua Capita*, and, when the Council of Trent thought itself assailed in this work, he wrote *Examen Concilii Tridentini*, a work of great historical value. His *Corpus doctrinae Prutenicum*, drawn up with Joachim Morlin (1567) was also studied as a work of great authority.

CHEMNITZ, kēm'nīts, city, Germany, Circle of Saxony, at the base of the Erz Gebirge, and at the confluence of the Chemnitz River with three other streams 43 miles south-southeast of Leipzig. The city consists of an older inner town, almost circular in form, intersected by narrow streets, completely surrounded by modern suburbs. Among its numerous squares and public places are the Hauptmarkt, which contains the old Rathaus; the Neumarkt; the Königsplatz; with the Church of St. Peter and the Technical Schools. The city owns its water, gas, and electric works. Its educational institutions include a gymnasium, schools of agriculture, commerce, engineering and the various crafts. There is also a municipal library of over 35,000 volumes. Its manufactures and industries include: textiles, carpet, hosiery, machinery, chemicals, musical instruments, bicycles, automobiles, and electrical equipment.

Created a free imperial city as early as 1125, Chemnitz suffered much during the Thirty Years' War; but later in the century the introducing of cotton manufacturing revived its prosperity. Its growth before World War I was phenomenal. During World War II it was occupied by American forces in April 1945. Pop. (1939) 334,563; (1946 est.) 250,188.

CHEMOSH, kēm'mōsh, the national god of the Moabites, who were on that account called "the people of Chemosh" (Numbers 21:29; Jeremiah 48:46). In Judges 11:24, Chemosh is mentioned as the god of the Ammonites, but the whole narrative here applies to Moab, and not to Ammon. Milcom was the national deity of the Ammonites. The Moabite Stone was erected to commemorate victories achieved by the aid of Chemosh. In the inscription upon it Ashtar-Chemosh is mentioned, apparently a goddess associated with Chemosh. Human sacrifices seem to have been occasionally offered up to Chemosh (II Kings 3:26, 27). The worship of Chemosh was introduced among the Hebrews by Solomon, who "built an high place for Chemosh, the abomination of Moab, in the hill that is before Jerusalem" (I Kings 11:7). Some have identified Chemosh with the sun, others with Saturn, while still others have regarded him as a war-god. These identifications are valueless. Chemosh doubtless bore the same relation to the Moabites as did Yahwe to the Hebrews.

CHEMOSURGERY, kēm-ō-sūr'jēr-ī, the removal of tissue, such as malignant, gangrenous or infected tissue, after it has been fixed by chemical means. In the treatment of external cancer the purpose of the fixation *in situ* is to facilitate the systematic microscopic control of excision through the use of frozen sections.

FREDERIC E. MOHS, M.D.,
The University of Wisconsin-State of Wisconsin
General Hospital.

CHEMOTHERAPY, kēm-ō-thēr'a-pī, a term applied to the utilization of chemical agents

in combating disease. While serum, vaccine, and toxin therapies depend on stimulating the body's efforts to fight invading organisms, drugs used in chemotherapy directly attack the invaders and kill or inhibit them without serious damage to the body cells. Effective chemotherapeutic agents must be more toxic for the infecting organism than for the body. Mercury is such an agent, used in Europe to treat syphilis as early as 1500; other metal agents are arsenic, antimony and bismuth. Quinine, ipecac, the sulfa drugs (sulfonamides), and the antibiotics (q.v.) are also used in chemotherapy.

CHEMOTROPISM, kē-mōt'rō-pīsm, orientation (q.v.) by diffusing molecules, as where animals are mechanically attracted to their food by the sense of smell. This is positive chemotropism. Negative chemotropism consists in movements away from some reagent. Odoriferous particles are diffused or radiate from a center; chemotropism is thus analogous to heliotropism (q.v.).

CHEMULPO, chē-mūl'pō, Korea. See IR-CHON.

CHEMUNG, in geology a group of nearly 1,000 feet of Upper Devonian sandstones and shales named by James Hall in 1839 from the Chemung River in western New York. The rocks form the upper division of the Seneca Series, overlying the Genesee and Naples or Portage, and being succeeded by the Chautauquan Series; the corresponding time has been called the Chemungian Stage. The typical Chemung is of fossiliferous marine sands laid near shore, grading eastward into stream-laid red beds, part of the great delta that spread westward from mountains formed in western New England in the Acadian or Shickshockian orogeny. Westward, Chemungian rocks become finer-grained, more muddy, and pass into black bituminous shales of deeper water origin in Ohio. Shales near Rockford, Iowa, are noted for their abundant well-preserved fossils, particularly the brachiopods; similar forms are known from localities from Arizona to the Mackenzie River. See also DEVONIAN SYSTEM; GEOLOGY.

CHEMUNG, shē-mūng', Battle of the, in the Revolutionary War, Aug. 29, 1779, the decisive battle in Gen. John Sullivan's campaign to harry the Iroquois country. The Indians and their Tory allies made a stand in force at the Chemung River, about a mile southeast of Newtown (Elmira), N. Y.

CHEMURGY, kēm'ūr-jī, the name used for a comparatively new agricultural concept. It has to do with extending the industrial utilization of farm-grown raw materials through applications of science. More specifically, chemurgy is concerned with nonfood uses of farm crops, with new crops, and with utilization of farm wastes.

The term *chemurgy* is correctly used to describe this concept, rather than to define a science. Although often loosely called "the science of chemurgy," such use is inexact, since chemurgy involves not only chemistry, but also physics, agronomy, engineering, and still other sciences and arts. The term was coined the Egyptian root word *chem* and the Greek word *ergon*, with a literal meaning of "putting chemistry to work." Frequently the phrase

is "farm chemurgy," or putting chemistry (and allied sciences) to work for agriculture.

The idea had its origin in 1926 after a flood of legislative proposals had been offered to rescue agriculture from the surplus problems which had plagued farmers since the 1921 depression. Techniques of farm production appeared to be enlarging food output faster than population was growing. Foreign markets were not increasing. None of the political schemes promised permanent advancement of agricultural living standards.

In the face of these conditions note was taken of the rising chemical industry, in that decade making tremendous forward strides both in research and production. The possibility was suggested that since the human stomach was of limited elasticity, and since effective food demand could hardly be expected to consume all the potential production, nonfood industrial markets might be developed. The thought was advanced that if such markets could be adequately increased, an expanding and improving agriculture would still be possible and a strong rural population of independent, home-owning farmers might be maintained on the American land.

Farm raw materials, of course, had long before been used for inedible and nonwearable purposes. The Egyptians had included straw in making bricks. Cordage, charcoal, and ethyl alcohol were existing examples of what are now described as chemurgic products. However, the concept of an organized effort to develop industrial uses for farm materials had never been expressed until the appearance of an editorial in *Farm and Fireside*, October 1926. Since then the idea of chemurgy has become widely accepted, not only as a program for improving agricultural wealth and well-being in the United States and in conditions but as a means of advancing popular other nations.

An organization for promotion of the chemurgic idea was set up at Dearborn, Mich., in May 1935, following a conference of farmers, manufacturers, and scientists. Active since then, the National Farm Chemurgic Council has members in all states and in more than 30 foreign countries.

Three prime factors opened the way for chemurgy to emerge at this particular time. These were (1) organic chemistry; (2) plant genetics; and (3) power machinery.

Before the rise of organic chemistry at the close of the 19th century, farmers had little opportunity to market crops for other purposes than for food or for such fibers as could be processed mechanically or by hand. The organic chemical industry created huge demands for cellulose, proteins, starches, oils, sugar, and other natural chemical compounds available from plant life. Many of these compounds are produced by nature, through plant growth, more cheaply than they can be synthesized in the factories. The chemical industry thus became a wholly new outlet for agricultural raw materials, with the factory "stomach" supplementing the human stomach as a source of demand.

The science of plant genetics came into being just before the turn of the century. With this new knowledge plant breeders found themselves able to change the composition of farm crops, to improve their quality and yield, and to adapt them to specific purposes. As an example, soybean varieties have been bred with larger yields of oil. The sugar content of the sugar beet has been increased from 11 per cent to 17 per cent or more.

Geneticists are able to modify plants to make them more suitable as crops for industrial consumption.

The advent of internal combustion and electrical power machinery has lowered the cost of producing most crops. Consequently farmers are now able to grow crops as industrial raw materials and to offer them, with profit to themselves, at price levels competitive with alternative sources. Power machinery is playing an increasing part not only in the preparation and cultivation of the soil itself, and in harvesting the crops, but in their transportation, compressing, dehydration, maceration, and in various forms of partial processing and adaptation for industrial consumption.

Soybean.—Undoubtedly the soybean has become the most widely known chemurgic crop. First brought to the United States early in the 19th century, for more than 100 years it received little attention. By 1914 production amounted to 50,000 bushels and by 1920 had grown to 1,000,000 bushels. Research then rapidly developed better growing methods; mechanical methods for cultivation and harvest were improved, and as additional uses were found demand increased. By 1935 the crop reached 100,000,000 bushels; by 1950 this figure had been trebled.

The soybean has an oil content of around 20 per cent. The United States had long been deficient in production of vegetable oils, both edible and inedible. Soybean oil, found by chemists to possess exceptional versatility, was welcomed in industry as a complement to the insufficient supplies of flaxseed, cottonseed, palm, and other oils. At first soybean oil was regarded as ill suited for paints because it dried somewhat more slowly than flaxseed oil. This problem was overcome and substantial quantities are used in paint. Industrial products into which soybean oil enters include lacquer, enamel, resins, putty, calking compounds, linoleum, oilcloth, printing inks, and many others. Most of the soybean oil is consumed in cooking fats, margarine, and salad oils.

The meal which remains after the oil is extracted has a protein content of 53 per cent. Manufacturers of livestock feeds consume nearly the whole output. Refinement of the meal, however, has resulted in the extraction of various materials of higher value. One of these is lecithin, a phosphatide formerly obtained from the yolks of eggs. Soybean protein has had a large market in the manufacture of glue. Efforts to produce textile fibers from soybean protein have so far not been commercially successful. Plastic makers utilize soybean meal to some extent.

The consumption of soybeans for food and feed considerably exceeds their strictly chemurgic uses; the 15 per cent to 20 per cent of the crop demanded by nonfood industries has been a major factor in keeping the farm prices of the beans at more satisfactory levels than most other crops have maintained during the past two decades.

Corn.—United States farmers produce nearly 3 billion bushels of corn annually, and four fifths of it is utilized as feed on or near the farms where it grows. The 20 per cent which is sold for cash and enters industry finds more than 200 different end uses. Starch is the principal chemical component of corn. The grain also contains protein and oil. The textile industry, laundry operations, and papermaking are the three largest nonfood consumers of cornstarch. The quantity used in food is second to that consumed in textile manufacture.

Dextrin, made by further processing of starch, meets many kinds of needs for adhesives and binders, from postage stamps to battery compounds. Corn sugar and sirup serve for many sweetening purposes. Conversion of corn sugar into sorbitol, mainly used as a moistening agent, has become a large industry, with other sugar forms as byproducts. The oil from the corn germ is extracted for cooking and salad oils.

Industrial alcohol ranks among the important products of corn, especially since large quantities are required in the manufacture of synthetic rubber. A new and special variety of corn, known as waxey maize, is grown extensively for tapioca and adhesives. Its particular value arises from the differing molecular structure of its starch. The protein of corn, known as zein, has become an important industrial product. First widely used as a coating for paper to wrap grease- and oil-bearing materials, zein has become the source of a fiber which, under the trade name of Vicara, is blended with other fibers in numerous popular fabrics to which it lends desirable qualities.

Corn cobs.—Each bushel of corn yields about 14 pounds of cobs which formerly were a complete waste, undesirable even for soil conditioning. Before World War II ground cobs came into considerable demand for use in sandblast machines to polish delicate machine parts. Furfural, however, has become the main outlet for cobs.

Furfural was first produced commercially from oathulls, and still consumes practically all of these which are available. Requirements for furfural, however, have increased until oathulls are no longer in sufficient supply. Furfural found its first large uses in the refinement of lubricating oils and in resinous adhesives. Then it was found to be a desirable source for a nylon intermediate, and a large factory was erected to process it for that purpose. A large percentage of nylon fiber now derives from furfural.

Castor Bean.—Profitable new crops are sought by chemurgists. Out of some 300,000 species of plants known to botanists, less than 1 per cent are turned to human account. While not new, the castor bean has been grown in increasing acreages, mainly in the Southwest. The primary value lies in the oil which, when dehydrated, becomes a superior drying oil, and finds important uses as a lubricant and in brake fluids. It has special values because of its properties for withstanding extreme temperatures, both high and low.

Flax Straw.—Formerly straw was a farm waste which, like corn cobs, had no use on or off the farm and had to be disposed of. The straw is left after the seed has been threshed. Large quantities from Minnesota and California are now used to make cigarette paper. Formerly nearly all cigarette paper was made in France from old linen rags collected from central Europe. The American industry now meets all requirements. Paper for currency and for books such as Bibles also is made from flax straw.

Chlorophyll.—Chlorophyll has achieved various uses in the pharmaceutical trades. In the United States the extract is derived mainly from alfalfa, although broccoli and some other green plants are excellent sources.

Dehydration.—Markets for perishable fruits and vegetables have always been limited both in time and area, except as preservative methods have been developed. Canning does not materially

reduce weight or bulk; freezing requires refrigerated storage. New successes have been obtained in efforts to reduce perishable foods to powdered forms that may be conveniently packaged, will remain stable over long periods, and be palatable when reconstituted. An orange powder which, after standing months in a can at room temperatures, will make excellent orange juice, has been manufactured on a small scale after meeting military requirements. It promises to open markets where refrigeration is unavailable and at distances where oranges or canned juice cannot be shipped economically. Promising results also have been obtained with tomatoes. Experiments with other fruits and with potatoes, milk, and eggs, indicate that the new processes of dehydration will solve the former difficulties which made dried products unpopular because of unpalatability. If these efforts succeed they will help to stabilize farm prices of perishable items, extend their markets, and improve food supply and variety in several areas.

Research.—As the possibilities of chemurgic approaches to plant raw materials have become better understood, research has steadily pursued new developments. The United States government has established four large regional laboratories which are devoted to finding new uses for farm products and better processes for their utilization. Out of these laboratories have come such advances as frozen citrus juice concentrates, now widely used; the new orange powder previously mentioned; a process for deriving plasticizing materials from animal or vegetable fats, already in extensive commercial use; tanning materials from canaigre, a root which grows wild in the Southwest; and many improvements in processes using farm materials. A notable achievement was a practicable commercial process for making penicillin cheaply in quantity. Private industrial research into the chemurgic uses of farm materials has advanced even more extensively.

Chemurgic research in its continual examination of farm materials has taken into account the food needs of an enlarged population. Numerous processes have resulted in improvements in food manufacture and total supply.

Chemurgy has increased the number of uses and enlarged the markets for many farm products, and has helped to introduce new products into agriculture. It has found profitable uses for several farm wastes. It has created new markets, new jobs in processing products of the soil, new markets for industrial activity, and some new products for the American standard of living.

The National Farm Chemurgic Council, which serves as a continuous clearing house for chemurgic information, is located at 350 Fifth Avenue, New York 1, N. Y.

WHEELER McMILLEN,
Chairman of the Board, National Farm Chemurgic Council.

CHENAB, chē-nāb' (ancient ACESINES) river, in India, Kashmir, and West Pakistan, of the "five rivers" of the Punjab. Affluents are the Jhelum and the Ravi. It rises in the Himalayan ranges of Kashmir, and, entering West Punjab, Pakistan, near Sialkot, flows in a south western direction until it unites with the Sutlej River after a course of about 675 miles. The combined stream flows 50 miles further to Indus. The Chenab is of great importance to West Punjab because of its huge irrigation sy

tem: the Lower Chenab Canal (completed in 1892) and the Upper Chenab Canal (completed in 1912) irrigate some 2,500,000 acres of land in the Rechna Doab area.

CHENEDOLLE, shân-dô-lâ', Charles Julien Lioult de, French poet: b. Vire, Normandy, 1769; d. castle of Coisel, 1833. The French Revolution forced him to emigrate in 1791; later he served in the corps of the prince of Condé, and did not return to Paris until 1799. He was a friend of Mme. de Staël and a devoted admirer of René de Chateaubriand. His poetry, considered transitional between classicism and romanticism, is best known through *Le Génie de l'homme* (1807), *L'Esprit de Rivarol* (1810), and *Études poétiques* (1820). Charles A. Sainte-Beuve published in 1864 Chénedolle's complete works.

CHENERY, ché'nér-ī, Thomas, British publicist and Orientalist: b. Barbados, West Indies, 1826; d. London, England, Feb. 11, 1884. He was a correspondent for *The Times* of London in Istanbul from 1854 to 1856. After his return to London he remained on the staff of the paper as a writer and reviewer, until in 1877 he succeeded John T. Delane as editor. He is mainly remembered, however, for his scholarship in Semitic philology, as he mastered both Hebrew and Arabic. He was lord almoner's professor of Arabic at Oxford until 1877 and was one of the revisers of the Bible until shortly before his death.

CHENEY, ché'nī, Ednah Dow Littlehale, American abolitionist, woman suffragist, and author: b. Boston, Mass., June 27, 1824; d. Jamaica Plain, Mass., Nov. 19, 1904. She was an organizer in educational, religious, and social causes, and was particularly active in welfare work during the Civil War. Besides several novels, she wrote a biography of her husband, Seth Wells Cheney, one of Louisa May Alcott, and her own reminiscences.

CHENEY, John Vance, American poet and essayist: b. Groveland, N. Y., Dec. 29, 1848; d. San Diego, Calif., May 1, 1922. He was librarian of the San Francisco Public Library, 1887-1894, and of the Newberry Library in Chicago, 1894-1909. His volumes of verses include *Thisle-Drift* (1887) and *Poems* (1905); the finest of his critical essays were *The Golden Guess* (1892) and *That Dome in Air* (1895).

CHENEY, Seth Wells, American engraver and crayon artist: b. South Manchester, Conn., Nov. 26, 1810; d. there, Sept. 10, 1856. With his brother, John Wells (1801-1885), he became an engraver in Boston, Mass., in 1829; his finest plate was *Mother and Child*, engraved after the painting by Washington Allston. In 1833 he joined his brother in Paris where, while studying art, they supported themselves by engraving for American publishers. In 1838 the two brothers were associated with a third, Ward Cheney (1813-1876), in organizing a silk manufacturing company at South Manchester. From 1840 Seth had an art studio in Boston, where he proved highly successful in executing crayon portraits. He never attempted historical or genre subjects, and only rarely would he group two or more figures. His portrait studies included those of George Parker, William Cullen Bryant, and Charles Russell Lowell. Among popular crayon

drawings were *Rosalie* and *A Roman Girl*. In 1853 he married Ednah Dow Littlehale Cheney (q.v.).

CHENEY, Sheldon (Warren), American dramatic and art critic: b. Berkeley, Calif., June 29, 1886. After graduating from the University of California in 1908 he was associated with several periodicals as dramatic or art critic, and in 1916 founded the *Theatre Arts Magazine*, which he continued to edit until 1921. He spent the next few years in New York City, principally associated with Equity Players (The Actors' Theatre). Thereafter he devoted himself to lecturing and writing on modern art; opposed to academism in all fields of art, he maintained that creative vision and spiritual experience were the most practical elements in preparation for living. Most often reprinted of his numerous books was *A Primer of Modern Art* (1923), and *The Theatre: 3000 Years of Drama, Acting, and Stagecraft* (1929; revised and enlarged ed., 1952) became a standard history of the subject. Later books included the highly controversial *Expressionism in Art* (1934), *Art and the Machine* (1936), written with his wife Martha Candler Cheney, and *Men Who Have Walked with God* (1945).

CHENGTEH, chŭng'dŭ, or **JEHOL**, jě-hōl', city, China, capital of Jehol Province, in southwest Manchuria, 110 miles northeast of Peiping, to which it is connected by railroad. The gateway to Manchuria, Chengteh is enclosed by walls and is an important commercial center with a trade in wool, hides, and furs; silk weaving is carried on. The name Jehol is derived from Je Ho, "Hot River," a stream flowing nearby, the waters of which are said to be lukewarm. Chengteh has long been noted as the summer residence of Chinese emperors. The imperial palace, built around 1700, is located in a large walled park containing also several pavilions, a lake, a theater, and even lamaseries. The city was taken by the Japanese in 1932 and was restored to China in 1945. Pop. (1947 est.) 60,000.

CHENG TU, chŭng'dōō', city, China, capital of Szechwan Province and river port on the Min River, a tributary of the Yangtze, is located 170 miles northwest of Chungking. Its importance is mainly that of an agricultural trade center, as it lies in an exceedingly fertile plain, one of the most populous areas of China. An irrigation system, first devised in the 3d century B.C. and still in use, has added greatly to the natural fertility of the alluvial soil. Tea, tobacco, rice, wheat, potatoes, and sugar are raised in great quantities. Salt, produced in the vicinity, is also traded on a large scale, and cotton and silk textiles and matches are manufactured. One of the oldest cities of China, Chengtu is a flourishing cultural center, having two universities, a college of sciences, and other educational institutions. During World War II United States air bases were built nearby. Pop. (1948) 647,877.

CHENIER, shā-nyā', André Marie de, French poet: b. Istanbul, Turkey, Oct. 30, 1762; d. Paris, France, July 25, 1794. The son of Louis de Chénier (1722-1795), consul general in Istanbul and Morocco, André was secretary to the French ambassador in London from 1787 to 1790, and thereafter devoted himself to literary pursuits. Though at first an ardent supporter of

the French Revolution, he protested vigorously against the excesses of the Reign of Terror, helped prepare the defense of the king, and became an anti-Jacobin. He was arrested at a friend's house March 7, 1794, imprisoned and guillotined July 25, only two days before the fall of Maximilien de Robespierre. Although little known in his day, Chénier has long been regarded as one of the finest French poets of neoclassicism, his chief characteristics being purity of form combined with vigor of thought and of expression. He wrote idyls, elegies, odes (including one to Charlotte Corday), and dithyrambs. Of his love poems, the finest are those dedicated to Fanny. Among his best known compositions are *L'invention*, *Jeu de Paume*, *A la France*, and his *Bucoliques* and *Épîtres*. In prison he composed a beautiful elegy *La Jeune captive* and the *Iambes* which, owing to their spiritual affinity, are often likened to the poems of John Keats. His complete works were first published in Paris in 1819; several editions followed. Umberto Giordano's opera *Andrea Chénier* is based on the life of the poet.

CHENIER, Marie Joseph de, French dramatist and politician: b. Istanbul, Turkey, Feb. 11, 1764; d. Paris, France, Jan. 10, 1811. He was the younger brother of André Marie de Chénier. A whole-hearted Republican, he was a member of the National Convention, of the Jacobine Club, and of other revolutionary organizations. His tragedies—*Charles IX* (1789), *Henri VIII* (1791), *Caius Gracchus* (1792), *Fénelon* (1793), *Timoléon* (1794)—brought him fame and success more for their revolutionary tone than for their intrinsic value. The last tragedy, *Tibère*, however, is considered one of the best of the old classical school. Chénier also wrote the words for national songs: the *Chant du Départ* gained immense popularity. His works, collected in 8 volumes, appeared in Paris in 1824–1826.

CHENILLE, shě-nēl', a round fabric or trimming, made by uniting with two or more sets of warps, either by weaving or twisting, a fine filling or weft, which is allowed to project beyond the warps. This filling is cut at its outer edges and the fabric is then twisted, assuming a cylindrical shape with weft projecting radially from the central line of warps. Chenille may be of silk, worsted, wool, or cotton.

CHENNAULT, shě-nōlt', **Claire Lee**, United States Army Air Force officer: b. Commerce, Texas, Sept. 6, 1890. During World War I he served with the aviation section of the signal corps reserve, and in 1920 he was commissioned 1st lieutenant in the army's air service. He commanded a pursuit squadron in Hawaii from 1923 to 1926, and thereafter varied duties included teaching assignments at flying schools. By 1935 he had reached the temporary rank of major, and two years later, having resigned his commission, he went to China as adviser to the Chinese Air Force. In 1941 he organized a group of American volunteer fliers in China (the Flying Tigers) for service against the Japanese, and the next year, following entry of the United States into World War II, he was recalled to duty with the United States Army Air Force. With the rank of brigadier general he was given command of the China Air Task Force, and in 1943, promoted major general, he became com-

manding officer of the 14th United States Air Force. He relinquished his air command on July 15, 1945, and on October 31 retired from the air service. Returning to China in 1946, he organized an airline to carry relief to stricken areas of the country. In March 1948 he appeared before the House Foreign Affairs Committee urging United States military aid to Nationalist China. His autobiographical *Way of a Fighter* was published in 1949.

Consult Mims, S., *Chennault of the Flying Tigers* (Philadelphia 1943), and Ayling, K., *Old Leatherface of the Flying Tigers* (New York 1945).

CHENONCEAUX, shě-nōn-sō', village, France, in Indre-et-Loire Department, on the Cher River, 18 miles east-southeast of Tours. Its fame is due to the château, started in 1515 by Thomas Bohier, tax receiver under Francis I. It came into the hands of Henry II, who gave it to his mistress Diane de Poitiers, later dispossessed by Catherine de' Medici. The castle lies on an islet in the river, and in 1560 Philbert Delorme, celebrated French architect, built a wing spanning the river, about 200 feet wide at this point. A later owner, Madame Dupin, held here a literary salon. Pop. (1946) 220.

CHENOPODIACEAE, kē-nō-pō-dī-ā'sē, a family of herbaceous dicotyledons containing the garden vegetables beet, spinach, and Swiss chard as well as many common weeds. The family comprises about 102 genera and 1,400 species.

CHENOPODIUM, kē-nō-pō-dī-ūm, **GOOSEFOOT**, a genus of about 250 species of herbs belonging to the family Chenopodiaceae and distinguished by its usually mealy texture, its small green, apetalous, usually perfect flowers and its fruit consisting of a membranous coat containing a flat, shining black seed. The common name derives from the fancied resemblance of the leaves of some of its species to the webbed foot of a goose. The genus is primarily known for its weedy members, but a few species have positive economic value. *C. album* (lamb's-quarters or pigweed), a common, white-mealy weed of cultivated areas and waste ground. Young plants are commonly used as a pot herb. *C. amaranticolor*, large annual grown as an ornament for its bright violet-red top foliage and as a pot herb. *C. brodiaeoides* (American wormseed, Mexican teal), strong-smelling herb of tropical America yielding an oil that is used medicinally as a remedy for intestinal worms. *C. bonus-henricus* (Good Henry or wild spinach), a weed of churches and waste places in Europe and America which sometimes used as a pot herb. *C. botrys* (feather geranium, Jerusalem-oak), an annual grown for its strong, aromatic odor and its attractive flower appearance. *C. quinoa* (the quinoa of Peru, large perennial of Central America where it has been cultivated for centuries for its seeds which are extensively used to make soups and bread and, when fermented with millet, a mildly alcoholic drink.

DONALD G. HUTTLES

CHEOPS. See **KHUFU**.

CHEPSTOW, chěp'stō, urban district, Wiltshire, a river port in Monmouthshire, on the River, two miles above its junction with the Severn and 14 miles northeast of Newport. It has

aved and well-lighted streets. The principal edifices are the church, a fine specimen of Norman architecture, and the old castle, the ruins of which crown a lofty cliff overhanging the Wye. The ruins of Tintern Abbey are in the vicinity. There is a river and coastal trade. The beauty of the environs is an attraction to visitors. Both the town and the castle are referred to in *Domesday Book*. Pop. (1951) 5,285.

CHEQUE, the British usage for *check*. See **COMMERCIAL PAPER—Checks**.

CHEQUEEN, or **CHEQUIN**, more correctly **SEQUIN** (It. *seccino* from *secca*, the mint), an obsolete Italian gold coin which originated in Venice. See **SEQUIN**.

CHEQUERS, chĕk'ĕrz, an official country residence for British prime ministers, presented for that purpose by Sir Arthur Lee, K.C.B., M.P., in 1921. In 1917, the actual transfer of the property to the nation was not to have taken place during the lifetime of the owners; however, the plans were changed in 1920. The place is maintained in perpetuity as the official country residence of the prime minister for the time being, or, failing him, the full privileges of residence to be offered in turn to the chancellor of the exchequer, the foreign secretary, the American ambassador, the speaker and four other Cabinet ministers. Chequers stands in a sheltered hollow of the Chiltern Hills, about 36 miles from London. The history of the mansion goes back to the 12th century; it contains a number of Cromwell relics, a fine library and a valuable collection of manuscripts and autographs, among which are the letters of Napoleon, Washington, Charles I, Pitt, and Franklin. The area of the estate is about 1,000 acres, consisting of gardens, grounds, farms, woods and Coombe Hill. The hill, 852 feet high, was presented to the nation in 1913.

CHER, shâr, inland department, France, having on the north Loiret, east Nièvre, south Allier Creuse, west Indre and Loir-et-Cher, and formed of parts of Berry, Bourbonnais, Nivernais, and Orléanais. It is named from the river Cher, which traverses it southeast to northwest. Area, 2,200 square miles; capital, Bourges.

This department is included in the basin of the Loire, which forms the greater part of its eastern boundary. The climate is mild and pleasant. The place is generally flat but is diversified in the north by chains of inconsiderable hills. The soil is fertile but is fertile in the neighborhood of the Loire and Allier. Heath and sand prevail in the northern districts. The forests occupy about one-sixth of the area and furnish large quantities of fuel for the ironworks and timber for shipbuilding. Pastures are extensive and sheep very numerous. Grains, chestnuts, hemp, vegetables, and wines are among the important products. Beets, buckwheat, and flax are also grown. Minerals consist of iron, lithographic stones, building- and grind-stones, flint, marble, and potter's earth. The preparation and manufacture of iron is the principal branch of industry. The manufactured articles are metal ware, fine and common cloth, woolen goods, porcelain and earthenware, sacking, beet sugar, nut oil, paper and glass. The department is divided into two arrondissements, 29 cantons and 893 communes. Pop. (1946) 286,070.

CHER, a river of central France, rising in Auvergne in the department of Creuse and joining the Loire from the left near Tours; length, about 220 miles. It is navigable to Vierzon. This river gives name to the department of Cher.

CHERAGAS, shâ-râ-gâs', village, Algeria, in Alger Department, 6 miles west of Algiers. Table grapes are grown. Pop. (1948) 3,418.

CHERAN, châ-rân', town, Mexico, 23 miles north of Uruapan. Corn, sugar, tobacco and fruit are grown. Pop. (1944) 3,388.

CHERASCO, kâ-râs'kô (ancient CLARASCUM), commune, Italy, in Piedmont, in the province of Cuneo; near the confluence of the Stura di Demonte and Tanaro; 36 miles south of Turin. Its fortifications, once of great strength, were demolished by the French in 1801. It was repeatedly the object of contest between the French and Austrians in the wars of Italy, terminated in 1631 by a peace concluded here; and in 1796 Napoleon, by what is called the Armistice of Cherasco, obtained a free passage for his troops through the Sardinian states. The town is well built and has several silk mills. Founded in 1243, it has a castle, domed church, two triumphal arches, a gymnasium, and a technical school. It markets grain, wine, and truffles, and produces silk, flour, lumber, kilns, and cheese. Pop. 9,312.

CHERAW, chĕ'rô, town, South Carolina, in Chesterfield County; altitude 150 feet; 88 miles northeast of Columbia; on the Atlantic Coast Line and Seaboard Air Line railroads; on the Pee Dee River; and served by federal and state highways. Cotton textiles, lumber, and brick are the main manufactures. During the Civil War the Confederates maintained a supply depot here until captured by Gen. W. T. Sherman in March 1865. Some fine old residences and St. David's Episcopal Church and cemetery are interesting. Government is by mayor and council. Pop. (1940) 4,497; (1950) 4,836.

CHERBOURG, shâr'-bôorg, a seaport, France, in the department of Manche, 196 miles west-northwest of Paris, on the north coast of the peninsula of Cotentin, and nearly due south of Southampton. It has a strongly fortified arsenal, and consists of the old or civil town and the new or military (Port Militaire), the latter quite distinct from the former, and separated from it by the fortifications with which it is surrounded.

Cherbourg is a popular port for the embarkation and debarkation of transatlantic passengers, but it was its transformation into a great naval station that gave it its special importance. This was chiefly carried out under Napoleon I, Louis Philippe, and Napoleon III. The foremost port improvement was the breakwater, stretching across the entrance to the roadstead, which was formerly open to heavy seas from the north. It is more than two miles in length, of very massive construction, covers an area of 3,700 acres and consists of a longer (western) and a shorter (eastern) portion, forming at their junction a very obtuse angle pointing toward the north. There are a fort and lighthouse there at either end. The eastern entrance to the harbor, between the breakwater and the island of Pelée, is about 500 yards wide; the western entrance, between the breakwater and

Fort Chavagnac (on a rocky islet), is about 1,000 yards. Large ships of war enter through the western approach.

Cherbourg, an old Norman center, is probably of Roman origin, called in antiquity CAESARIS BURGUM or CORIALIUM. The English held possession of the place until about 1200 and again during the Hundred Years' War, when finally taken by the French in 1450. It was after leaving Cherbourg that an end was put to the career of the Confederate cruiser *Alabama*, when it was sunk by the Union cruiser *Kearsarge* (q.v.) in June 1864.

During World War II, on June 26/27, 1944, United States troops under Licut. Gen. Omar N. Bradley recaptured the city from the German occupation forces. Cherbourg suffered heavy damage during this engagement. Pop. (1946) 34,034.

CHERBULIEZ, shĕr-bŭ-lyă', **Charles Victor**, Swiss-French author: b. Geneva, Switzerland, July 19, 1829; d. Combs-la-Ville, Seine-et-Marne, France, July 1(2), 1899. Belonging to a family noted for literary attainments, he first achieved distinction as an art critic and political writer, publishing some of his essays under the pseudonym of G. Valbert. In 1864 he became one of the editors of the *Revue des Deux Mondes*, and was elected to the French Academy in 1881. His novels, equally successful in France and abroad, are characterized by a fine social and psychological analysis, with a marked bias for description of odd characters. Among these are *Le Roman d'une honnête femme* (1866); *L'Aventure de Ladislas Bolski* (1869); and *Samuel Brohl et Cie* (1877).

CHERBURY, LORD **Herbert of**. See **HERBERT**, **EDWARD**.

CHEREMKHOVO, chĭ-ryĕm'kŭ-vŭ, city, USSR, in southern Irkutsk Region (oblast) of the Russian SFSR, about 80 miles northwest of Irkutsk. It is located on the Trans-Siberian Railway, southwest of Lake Baikal. The center of a major coal basin, its development in the 20th century has been rapid. Apart from coal mining, there are chemical, synthetic rubber, machinery, brick, and processing industries. Pop. (1939) 65,907.

CHERIBON or **TJIREBON**, chĕr-ĭ-bŏn', town, Indonesia, on the north coast of Java, about 125 miles east-southeast of Djakarta. A seaport on the Java Sea, at the mouth of the Cheribon River, it has a good harbor that ships sugar cane, coffee, indigo, copra, rice, and teakwood. Industries include textiles, chemicals, cigars and cigarettes. Cheribon is the site of a Moslem shrine to Gunung Djati. It was the capital of a former sultanate, abolished by the British in 1815. Under the Dutch administration it was the center of a residency of that name. Pop. (1950) 51,732.

CHERIMOYA, chĕr-ĭ-moi'ă, the fruit of *Annona cherimola*, a plant of the family Annonaceae, native of South America and related to the custard-apple. It is a heart-shaped fruit with a scaly exterior and numerous seeds buried in a delicious pulp. Both flowers and fruit emit a pleasant fragrance. This fruit is now cultivated in various tropical regions.

CHERKASSY or **CHERKASI**, chĕr-kăs'sĭ, town, USSR, in the Ukrainian SSR, 90 miles

southeast of Kiev. It is situated near the right bank of the Dnieper, on the railway line connecting Chernigov and Odessa. Beet sugar, tobacco, and lumber are the main products of the surrounding region. Cherkassy was an important town of the Ukraine in the 15th century. It remained under Polish rule until the revolt of the Cossacks in 1648. Russia annexed it in 1795. During World War II German troops occupied it in 1941, but the Russians recaptured it, Dec. 14, 1943. Pop. (1939) 51,693.

CHERKESS AUTONOMOUS REGION, chĕr-kĕs', oblast, USSR, in the RSFSR and the southwestern Stavropol Territory of the western Caucasus. The capital is **CHERKESSK** (1939 pop. 28,646). Its inhabitants are largely of Circassian stock, who were for long under Turkish rule. The region achieved its present status in 1928. It covers approximately 1,500 square miles; pop. (1946 est.) 150,000.

CHERNIGOV, chĭr-nyĕ'gŭf, administrative region (oblast), USSR, in the Ukrainian SSR, along the Desna River, is predominantly agricultural, yielding flax, cereals, potatoes, hemo, sugar beets, tobacco, livestock, and dairy products. Natural resources include lumber and peat. The region covers approximately 12,200 square miles; pop. (1946 est.) 1,700,000.

CHERNIGOV, city, capital of Chernigov Region (oblast), about 85 miles northeast of Kiev. It is a river port on the Desna, a tributary of the Dnieper, and is on the railroad from Odessa to Byelorussia. Among its chief manufactures are flour, spirits, leather goods, footwear, textiles, and lumber.

One of Russia's oldest cities, it is mentioned as a flourishing center in the early 10th century. From that time stem the numerous tumuli in the city's vicinity. Its Byzantine Cathedral of the Saviour, destroyed in World War II, dates back to 1024. In the 11th and 12th centuries Chernigov was the capital of Syever'sk principality. It was burned by invading Mongols in 1239. In the 14th century it was annexed by Lithuania, then captured and held by the Poles until taken by Russia in 1686. During World War II it was occupied by the Germans in 1941, but recaptured by the Russians, Sept. 21, 1943. Pop. (1939) 67,356.

CHERNOVTSY, chĕr-nŏf'tsĭ (Ger. CZERNOWITZ; Rum. CERNAUTI), administrative region (oblast), USSR, in the Ukrainian SSR, is located in the western part of the Ukraine, north of Rumania and northwest of the Moldavian SSR. The Dniester River bounds it on the north and east. Annexed by the USSR from Rumania in 1940, the region was formed from northern Bucovina and northern Bessarabia. On the eastern lowlands, wheat and sunflowers are the main crops, and cattle is raised both for meat and dairy products. In the west, there are large herds of sheep in the Carpathian Mountains. These highlands are wooded, containing much valuable timber. The population is predominantly Ukrainian. The region covers approximately 3,200 square miles; pop. (1947 est.) 900,000.

CHERNOVTSY, city, capital of Chernovtsy Region (oblast) about 140 miles southeast of Lvov, along the south bank of the Pruth River and on the Lvov-Bucharest railroad. It is an im-

portant railway center. Industries include textile mills, food-processing plants, breweries, and machine shops. Chernovtsy is an Orthodox archbishopric and has a university, founded in 1875. The city is ancient and was in the Middle Ages under the rule of the Russian principality of Kiev. From the 14th to the 17th centuries Poland controlled it. Austria, which came to occupy it in 1774, later made it the capital of the separate crownland of Bucovina (1849-1919). Following World War I, Chernovtsy was granted to Rumania until forcibly annexed in 1940 by the USSR, which thus gained control of strategic Carpathian passes. Recaptured by Rumania during World War II in June 1941, it was taken by the Soviet armed forces in March 1944. Of its once large Jewish population, few survived German persecution. Pop. (1941) 87,000.

CHERNOZEM. See BLACK EARTH.

CHERNYSHEVSKI, chër-nî-shâf'skû-i, -skî, **Nikolai Gavrilovich**, Russian radical thinker and critic: b. Saratov, Russia, July 12, 1828; d. there, Oct. 17, 1889. A disciple of Vissarion Grigorievich Belinski, he was greatly influenced by the French pre-Marxist Socialists and the materialistic philosophy of Ludwig Feuerbach. His early political writings called for mild reforms in Czarist Russia, such as universal education, railway construction, and freeing of serfs. Later he bitterly assailed the onerous terms on which the serfs were actually freed. During the 1860's he became one of the first Russian revolutionary publicists to participate actively in anti-Czarist secret societies, and thus led the Russian Populist (*Narodniki*) reform movement from philosophy into action. As result of his association with the radical "Land and Freedom" campaign, he was arrested (1862). In prison he wrote the influential utopian novel, *What Is To Be Done?* (1863). Sentenced in 1864, he spent most of his remaining life in Siberian exile. Chernyshevski is held in high esteem in modern Russia and is often described as the greatest scholar and thinker among Russian pre-Communist radicals. Among his critical works are *The Aesthetic Relations of Art to Reality* (1855) and *Lessing, His Time, Life, and Activities* (1856). He also did translations from Adam Smith, John Stuart Mill, and the German historian Georg Weber.

CHEROKEE, chër-ô-kê' (possibly from Creek *tsiloki* "people of a different speech"). The Cherokee of the southern Appalachians were historically and culturally one of the most important and numerous Indian peoples of the United States. If we take the population of aboriginal America north of Mexico to be about a million, the Cherokee with some twenty thousand comprised a considerable part of the total. Linguistically they are of Iroquoian stock, but culturally they are to be classified with their neighbors in the southeast. Physically they were a mixture of the Algonquian-Iroquois dolichocephalic type and the Eastern and Southern brachycephals.

The Cherokee "Nation" was a confederacy of towns which according to dialects may be divided into three groups. The Eastern or Lower dialect (characterized by an "r" which takes the place of "l" in other dialects) was originally spoken in the towns situated on the headwaters of the Savannah River. The tribal name of this group, *Tsa rage*, was corrupted by the English into the

form we know, while the Spaniards, meeting the Central and Western towns, wrote the name *Chalague*. The Middle or Kituhwa dialect was spoken in the towns on the Tuckaseegee and the head of the Little Tennessee in the very heart of the Nation, and it is spoken by the North Carolina (*Qualla*) remnant today. The Western dialect was spoken in eastern Tennessee, northern Georgia, and on the Hiwassee and Cheowa rivers in North Carolina. It has been the literary dialect and is the language of the Western Band.

The total number of towns was probably 50 or more, but not infrequently locations were changed and their populations varied greatly according to the seasonal patterns. Although Echota or Itsati on the Little Tennessee was the most important town, it cannot be regarded as a true capital.

Cherokee life was laid in a setting of woods, stream valleys, and mountains. Numerous species of evergreens and hardwoods sheltered deer, bear, buffalo, elk, wolf, panther, wildcat, turkey, pheasant, and rattlesnake. There seems to have been no living creature that was not sought out for its meat, pelt, or feathers. Maize, beans, squash, and tobacco were the chief cultivated plants. The diet was augmented and diversified by the collecting of nuts, seeds, and berries.

The Cherokee economic organization, based on a pre-sedentary agriculture, was characterized by a division of work between the sexes. Routine cultivation was largely the province of women, although land-clearing and ground-breaking were common enterprises. The crafts of conservation pertaining to agriculture also were performed by women, who were the principal makers of baskets, mats, and sieves. These were made from cane which abounded on the banks of the lower rivers, and from splints of the oak. Here we find the northernmost extension of the double weave technique, but Cherokee basketry and pottery were inferior to similar products of the Gulf peoples. Smooth ware was common, but a distinctive pottery was characterized by paddle-stamped designs which are possibly to be related to basketry patterns. There is some sign of intrusion of effigy motives from the Mississippi area. Mortars and pestles were of wood rather than stone.

The usual variety of stone knives, axes, celts, awls, and heads was available, and these of course were augmented by tools and weapons of wood and cane. The latter, an important material, was commonly fashioned into knives.

The preparation of skins and clothes seems to have been the woman's task, although man indulged in the more gratuitous forms of ornamental fabrication. The invariable article of male attire was a deerskin breechclout augmented with skin robes, moccasins and leggings as the terrain and weather required. Women wore a short deerskin skirt as a basic garment. The use of feather cloaks was probably more ceremonial and decorative than utilitarian. Headbands of feathers, skins, or metal were common. Cloaks were "finger-woven" of the inner bark of the mulberry, and belts, garters, and the like were made from bison and opossum hair. Quill work was lacking or rare.

Tattooing was a universal practice, and the southern Indian wore identification tags and cuff jottings which J. R. Swanton calls bulletin boards. Both face and body were painted in preparation for ball games, war, and other social functions. Extravagant ear decorations were common, although the Cherokee did not join the Creek and Chickasaw in ornamenting the nose. Perhaps they practiced artificial head-flattening as did other southern tribes. The men wore their hair shaved or plucked to a roach or crest, but the women did not cut theirs.

Ancient dwellings were circular structures of logs, poles, and bark, frequently faced with earth. Ramsey speaks of a conical windowless town hovel 30 feet in diameter and 20 feet high which was used as a council hall and for ceremonials. "Within it were beds, made of cane, rather tastefully arranged around its circumference . . . [it] had a single entrance. . . . There was neither window nor chimney." There is some mention of a square house of poles, probably of

Iroquoian derivation. During the summer, meetings and social functions were held in open lounging pavilions, the more elaborate of which had porches. Corncribs, granaries, and storage houses for skins, weapons, and valuables were common in the more populous towns.

Transportation aids were rare. Rafts and canoes made from hollowed logs were paddled along less precarious river passages. Sometimes dogs were used to carry burdens.

Hunting, particularly of deer, was managed by stalking and surrounds. Fish were secured by spear, bow, dams, and poisoned pools. The simple hand drill was used to make fire.

Man was the hunter, seeking deer for both its meat and pelt. Hunting was done chiefly with the bow and arrow, although the blowgun, fashioned from cane, was used for small game.

Social organization was characterized by matrilinear totemic clans. There were seven exogamous clans: *Ani-Wa ya* (Wolf), *Ani-Kawi* (Deer), *Ani-Tsi skwa* (Bird), *Ani-Gilahi* (Long-haired People), *Ani-Gatagevi* (obscure), *Ani-Saha ni* (obscure, perhaps Blue People), *Ani-Wa di* (Paint).

Political organization was bifurcate in form. The "Red" hierarchy consisted of a high priest of war and his assistants, scouts, surgeons, and a number of "pretty women," clan ladies of high position and considerable influence, devoted to the prosecution of war. The "White" hierarchy was devoted to the maintenance of peace and had its separate organization. Some towns were classified as Red or White, and the latter were places of refuge.

The Cherokee had been established in the southern mountains at least two or three centuries before their first contacts with Western civilization during the incursions of Hernando de Soto in 1540, and later 16th century explorers. Their early contacts with the white settlements in the southern colonies were characteristically those of frontier trading, and exploratory and skirmishing relations. Among the important 18th century explorers who have left records of travels among the Cherokee are William Bartram, James Adair, and Henry Timberlake.

At the outset the chief effect of white settlement on Cherokee society was indirectly through the coastal tribes and through the displacement of neighboring populations. Trade in animal hides, especially deerskins, became a part of the Cherokee economy. The gun was the most important addition to tribal technology. In the middle of the 18th century a disastrous smallpox epidemic weakened the tribe. It was, therefore, ill-equipped for the serious conflicts with the Carolina settlers which broke out shortly thereafter.

Displacement of the Cherokee occurred with great rapidity, and the frontier moved forward well ahead of land settlement. Between 1721 and 1783 ten treaties were made with the colonies or states, and ten cessions were made; and between 1785 and 1835 twelve treaties were executed with the United States, and the Cherokee holdings east of the Mississippi were obliterated.

By the time of the American Revolution, Cherokee claims had so narrowed and the game supply had so declined, that a completely sedentary economy could be foreseen.

Following the Revolutionary War the Cherokee were well supplied with horses, cattle, hogs, poultry, peach trees, potatoes, and bees.

native arts of pottery and basketry were pursued, and dress and housing were little changed from the aboriginal habit although of course augmented by borrowed items. Traders begot a numerous offspring; persons of mixed blood intermarried, and an influential half-breed population grew up.

Moravian missionaries worked among the Cherokees during the latter part of the 18th century, but it was not until the close of the century that mission activity can be regarded to have made a heavy impact on Cherokee life.

Undoubtedly the most remarkable achievement in the Cherokee history occurred in the early 19th century with the invention of a syllabic alphabet by Sequoya or Sequoyah (George Guess). The syllabary was so constructed that it could be mastered in a matter of days, and thus the Cherokee became a literate people almost immediately after the alphabet's formal adoption by the tribe in 1821. Type was cast in the characters and in 1827 the first Indian press north of Mexico was established. On Feb. 21, 1828 the first number of the Cherokee *Phoenix*, printed both in English and in the Sequoya syllabary, was published in New Echota. As a consequence of these events the Cherokee achieved a closer integration which led to a constitutional form of government. Sequoya visited the Arkansas émigrés to instruct them in the alphabet.

Toward the close of the 18th century the first of the voluntary migrations occurred which continued until the forceable removal in 1838. Some emigrants went to Louisiana, several thousands settled north of the Arkansas, and some even penetrated Mexico.

Pressures against the Cherokee lands persisted through the first quarter of the 19th century, although the tribe vigorously resisted further encroachment. The discovery of gold in the Cherokee country, however, lent the final impetus to the pressure for displacement, and in 1828-1830 Georgia passed laws extinguishing the government of the Cherokee and distributing their land, just as it had done with the Creeks a little earlier. Although this was in direct violation of the numerous treaties between the tribe and the United States, and although the United States Supreme Court found in favor of the Cherokee, no effective protection intervened. On Dec. 29, 1835 a part of the tribe, under the leadership of Major Ridge, Elias Boudinot, and Stand Watie, signed a treaty ceding all tribal lands in exchange for other land in Indian territory and a sum of \$5,700,000. This group, which came to be known as the Treaty or Ridge Party, agreed that removal of the tribe would be accomplished within three years. This treaty was vigorously opposed by a majority of the tribe under the able, if sometimes ruthless, leadership of Chief John Ross, and the consequent cleavage weakened the tribe for more than half a century.

In 1838 the forceable removal to Indian Territory of the bulk of the tribe was accomplished by armed forces of the United States, after resistance and some loss of life. Many more died on the march, which was apparently poorly planned and badly administered, and a few hundred eluded the net and escaped into the Great Smoky Mountains in western North Carolina where their descendants, now called the Eastern Band, remain more than a century later.

Conflict immediately developed between the Treaty Party and the Ross Party. Hopes for a peaceful settlement were impaired by the weakness

and vacillation of the United States government, which recognized both groups by treaty. The uneasy truce was finally shattered by the assassination in 1839 of three members of the Treaty party, Major Ridge, his son John, and Elias Boudinot. Intermittent fighting then ensued for more than a decade.

Despite these destructive events a formal constitution providing for a head chief, a bicameral legislature and a judiciary was adopted in 1839 by a constitutional convention of about 2,000. The instrument was based on the constitution of 1727. With amendments it remained the organic law of the Nation until the end of tribal government at the beginning of the 20th century. Relations with the United States government were never well worked out, M. L. Wardell says, since the federal government considered the Indian problem a minor one. Certainly army garrisons in Indian Territory often did more harm than good and the Washington government showed little understanding of Cherokee problems.

In 1844 the *Cherokee Advocate* began publication under the editorship of W. P. Ross, a Princeton graduate and the nephew of John Ross. It was printed both in English and the Sequoyia syllabary for about ten years and began publication again after the Civil War, continuing into the 20th century.

The Civil War once more precipitated internecine conflict, for the Cherokee held several thousand slaves and their lands lay in an area of active combat. John Ross, still chief of the Nation, negotiated an advantageous treaty with the Confederacy. Hundreds of Cherokee fought on both sides during the conflict which devastated much of the Indian territory. Following the war the Cherokee were required to give lands to the freed slaves.

In 1891 the Cherokee Outlet (or Strip) was sold in response to demands of the United States. This did not for long relieve the pressures on the common tribal lands and in 1906 a comprehensive act provided for the dissolution of the tribal government and the final disposition of lands. By the middle of the 20th century there were more than 40,000 persons of varying degrees of Cherokee ancestry west of the Mississippi.

The remnant who escaped the Removal and fled to the highlands of western North Carolina, after many vicissitudes were able to cling to a small area which was made into a reservation. By the mid-20th century there were over 3,000 names on the rolls of this Eastern Band of whom about two thirds actually resided on the reservation. Few surviving Cherokee are full-blooded.

CHEROKEE, city, Iowa, seat of Cherokee County, 48 miles northeast of Sioux City, on the Little Sioux River and the Illinois Central Railroad. The Sanford Historical Museum, the Sioux Valley Hospital, and a state hospital for

the insane are here. There are farm machinery works, creameries, and railroad repair shops. Settled in 1850, Cherokee was incorporated in 1873. Nearby is a huge glacial boulder known as Pilot Rock, a famous landmark. Pop. (1950) 7,705.

CHEROKEE, city, Oklahoma, county seat of Cherokee County. The city is a processing center for the wheat, alfalfa, corn, and sorghum of the district. Pop. (1950) 2,635.

CHEROKEE DAM, Tennessee, dam on Holston River, completed in 1942.

CHEROKEE NATION v. GEORGIA, a celebrated case in the Supreme Court of the United States concerning relations of the federal government with Indian tribes, decided in 1831. By terms of the Holston Treaty of 1791 the Cherokee Nation made a large cession of land in return for the government's guarantee of the territory retained by the Indians. Eleven years later, when Georgia ceded her western lands to the federal government, she obtained a promise that all Indians should be removed from her confines as soon as it could be done peaceably and on reasonable terms. This vague promise not having been fulfilled after more than a quarter of a century, the Georgia legislature by six successive acts—from Dec. 20, 1828 to Dec. 22, 1830—extended state laws and jurisdiction over the Cherokee lands, and ordered that they be distributed by lottery among Georgia citizens.

Early in 1829 the Cherokees appealed to President John Quincy Adams. He left the settlement to his successor, Andrew Jackson, a veteran Indian fighter whose sympathies were on the side of the Georgians. Despite all legal efforts to prevent them from carrying their case to the highest court, the Cherokee finally obtained a writ of error in a murder case from the Supreme Court, citing the state to appear. Georgia ignored the summons, as also a later one to respond to a request for an injunction against Georgia's interference with the Cherokee Nation's laws.

Chief Justice John Marshall and the majority of the Supreme Court decided on March 18, 1831 that the Cherokee were not a foreign nation in the meaning of the Constitution, since, for instance, an attempt by any other foreign nation to form a connection with them, or to trespass on their land, would be held an invasion of the rights or of the territory of the United States; that they were a domestic or dependent nation, in a state of pupillage, their relation to the United States being like that of a ward to its guardian; that their title to their land was only that of occupancy, the United States succeeding to it whenever their own possession lapsed; that their appeal lay to the president; and that the Supreme Court could not call out force to resist the extension of Georgia laws over territory claimed as its own.

A related case, *Worcester v. Georgia*, concerns the law restricting white men's residence in the Cherokee territory without Georgia's permission. Under this law, 11 missionaries were arrested and sentenced in September 1831 to four years' imprisonment. Nine accepted a pardon. However, the Rev. Dr. Samuel A. Worcester brought suit for a habeas corpus in the Supreme Court, which gave decision March 3, 1832. Here the court seemed to reverse itself, holding the state's acts violated treaties and

laws of the United States, and ordered the prisoner released as condemned on a void statute. The State refused to comply; but in place of waiting till the next term of the Supreme Court, to see if it would call on the United States authorities to enforce the decree, the prisoners made submission and were released. It is probable that Jackson's famous "John Marshall has made his decision—now let him enforce it," would have prevented them from regaining freedom till their term was up. Consult Hodge, F. W., *Handbook of American Indians* (Washington 1907).

CHEROKEE RIVER, the early name for the Tennessee River (q.v.).

CHERRY, the name of various species of trees and shrubs of the genus *Prunus*, family Rosaceae, closely related to the almond, peach, apricot and plum, thus comprising one of the most important groups of fruits—the drupaceous or stone fruits. Cherries are characterized by white flowers, usually in umbel-like fascicles, or in racemes, and subglobular, mostly red, yellow or black fruits, without bloom, and containing nearly globular, smooth stones. Few of the native species have attracted horticultural attention except for ornamental purposes, but some, especially, the wild black cherry (*P. serotina*), are highly prized as cabinet woods and for interior decorating.

The cultivated cherries have been derived almost wholly from two European species, *P. avium* and *P. cerasus*. The varieties of *P. avium* belong to three groups: hearts, heart-shaped, soft, light or dark, sweet fruits; bigarreaux; heart-shaped, firm, light or dark, sweet fruits; and dukes, light, somewhat acid fruits. Of these three groups the bigarreaux are the most important; they are largely grown in California and shipped to the Eastern markets. The hearts are somewhat grown for home use on both the Atlantic and Pacific coasts, in Europe and in Australia. The varieties of *P. cerasus* are divided into amarelle (light-colored) and morello (dark-colored) groups. The amarells are the leading acid cherries and most popular in the eastern United States, especially in western New York and Michigan, where they are largely canned and frozen. Most of them are used in pie making. The Montmorency is by far the leading acid or sour cherry variety. The leading sweet varieties (*P. avium*) are Lambert, Bing, Schmidt, Napoleon, and Windsor.

Besides these important species and their varieties, a few others have horticultural value, notably, *P. Mahaleb*, a hardy, rather small European species, which is used as a propagating stock; *P. pennsylvanica*, the pin, wild red, or bird cherry; *P. besseyi* and *P. pumilla*, the sand or dwarf cherries, which seem to grade into one another, the former producing sweet fruit, the latter acid, and which, being natives of the plains region, have been used by the hybridizers.

Cherries are propagated by budding upon either mazzard or mahaleb seedlings, the latter being in more general favor, especially in the West, because they are hardier, easier to grow, easier to bud and are freer from blight in the nursery. Sweet cherries succeed best upon well-drained light loams where the moisture is abundant but not excessive; sour kinds will stand

heavier but not wet land; neither prove profitable upon very rich soils. The ground should be thoroughly and deeply plowed and harrowed; the sweet kinds, which are large spreading trees, set 25 to 30 feet apart, and the sour kinds 15 to 20 feet. The land should be kept clean by frequent cultivation until midsummer, when a cover crop should be sown. This should be turned down the following spring, and the land treated as before. The principal fertilizer needed is nitrogen, which for most soils, should be applied in the late fall or early spring every year. The trees and fruits should be protected from attacks of insects and fungus diseases by systematic spraying.

The most serious insects of the cherry are the cherry aphid and the curculio. The cherry aphid is a small black insect that causes curling of the young leaves, and is controlled by spraying with nicotine sulphate. The plum curculio (see PLUM) is a small beetle whose larvae, or grubs, feed in the young fruits. It is controlled by lead arsenate spray.

The main fungus diseases of the cherry are brown rot of the fruit and leaf spot of the leaves. These are usually controlled with wettable sulphur sprays. For further information consult local state agricultural experiment station or Extension Division, United States Department of Agriculture.

Consult Hedrick, U. P., and others, *Cherries of New York* (Albany 1915); Havis, Leon, "Growing Cherries East of the Rocky Mountains," *Farmers' Bulletin* 776, U.S. Dept. of Agriculture (Washington 1948).

LEON HAVIS,
Plant Industry Station, Beltsville, Maryland

CHERRY, Wild, the bark of *Prunus serotina* collected in autumn. This is very extensively used in medicine as a vehicle basis, the syrup of the bark being used extensively in cough remedies. It contains a small amount of hydrocyanic acid.

CHERRY LAUREL (*laurocerasus officinalis*), a shrub closely allied to the common cherry, but having evergreen leaves, and is well known as an ornamental shrub.

CHERRY ORCHARD, The. Chekhov's realistic drama of Russian life, *The Cherry Orchard*, was first performed, with enormous success, at the Moscow Art Theatre in 1903, only a few months before the death of the author. Chekhov's literary activity was coincident with the deep depression that in the eighties of the last century spread over the "intelligentsia" of Russia, owing to the disappointing reaction following the war with Turkey. As a trained physician, Chekhov understands the diagnosis of this almost universal distemper and depicts it in his stories and plays. The title of *The Cherry Orchard* has a double meaning: It refers both to the actual orchard on the destruction of which hinges the plot of the play, and to Russia itself. The people of the play represent various types of Russian character. Madame Ranievskaya through weakness and mental inertia sacrifices her great estate and its chief glory, the famous cherry orchard; her daughter Vavara is alike inactive; Lopachin is the prosperous grandson of a former serf, into whose hands the estate passes;

the uncle Gayey is a type of the Russian who talks but who does nothing. The student Trofimov is a dreamer and idealist who sees what is the matter with Russia, and asserts that "in order to live in the present we must first redeem the past, and that can only be done by suffering, by strenuous, uninterrupted labor." With the faithful, unselfish old serf Fiers is contrasted the selfish young footman, Yasha.

Though the play ends with the prospect of a gloomy future for Madame Ranevskaya and her daughter, Trofimov sees the vision of a regenerated Russia; "Mankind goes on to the highest truth, and to the biggest happiness possible on earth, and I go in the very van." But the poor old serf Fiers is left behind forgotten and soon to die, and the sound of axes is heard in the cherry orchard. In its sincerity, its truth, its subtle characterization, and its idealism, *The Cherry Orchard* is representative of the best in modern Russian drama. It was first translated into English by George Calderon in 1912 and by Julius West in 1916.

NATHAN HASKELL DOLE.

CHERRY VALLEY, village, New York, in Otsego County, altitude 1,800 to 2,000 feet on the Delaware and Hudson Railroad, 54 miles west of Albany, and on state and federal highways. On Nov. 11, 1778 it was the scene of a massacre by Indians, Tories, and English, led by Joseph Brant and Walter Butler. The village has a "massacre monument," and many markers of historic spots.

It has good schools and churches, and a memorial library. The village was first settled in 1740. It is governed by a board of trustees, and owns its water system. Pop. (1940) 704, (1950) 90.

CHERRY VALLEY MASSACRE The Nov. 11, 1778), a surprise attack during the American Revolution on a frontier fort and surrounding settlement in the upper Susquehanna valley (Otsego County, N. Y.), led by the Tory Capt. Walter N. Butler, son of Col. John Butler, with Indian allies under Joseph Brant (q.v.).

General Lafayette, concerned over the exposed situation of Cherry Valley, had fortified it with a blockhouse the preceding spring; and Col. Peter Gansevoort, an experienced officer of high reputation, solicited the command. For some reason, however, it was given to Col. Ichabod Alden, a Massachusetts officer, not used to Indian warfare. During the summer the inhabitants lived in the fort and went warily; but by November they had returned to their dwellings. On the 8th, Colonel Alden received a message through a friendly Indian that at a great meeting of Tories and Indians at Tioga it was resolved to attack the place; and the people begged to be permitted to take refuge in the fort again. Alden ridiculed the report as an idle Indian rumor, assured them that he would guard against a surprise and sent out scouting parties. The party that should have beaten up Butler's went to sleep by a campfire on the night of the 9th, and awoke as prisoners of the enemy. Butler obtaining a company of his father's rangers, induced Brant, the great Mohawk chief, to join him with a few hundred of his Indians, picked up a band of Senecas and other straggling Indians and Tories as he went on, and with about 800 men approached Cherry Valley. Securing from the

prisoners, under threat of torture, all information as to the conditions there—as that the officers of the garrison lodged with families near the fort, instead of in it—the expedition camped about a mile southwest of the village on the night of the 10th. It snowed in the night, turning to rain in the morning. As the enemy approached under cover of the thick mist, an Indian fired on a stray settler and wounded him, but he escaped and warned the colonel, who thought the assailant only a straggling Indian, and paid no attention to the matter. The rangers stopped near the village to examine their guns, and the Indians sprang forward, the ferocious Senecas in advance, under their chief, Sayenqueraghta. In the massacre that ensued, 32 settlers, mostly women and children, the colonel and 15 soldiers, were slain; 30 to 40 prisoners were taken, also nearly all women and children; and the village was reduced to ashes. Most of the prisoners were released the next day, and sent back to effect an exchange for Butler's mother and younger brothers and sisters, in the power of the Americans.

CHERRYVALE, city, Kansas, in Montgomery County, altitude 837 feet, 150 miles southwest of Kansas City, on the Santa Fé and Saint Louis and San Francisco railroads. In a farming country with oil and mineral resources, the city manufactures flour, zinc oxide, garments, butter, oils and greases, farm equipment, brick and cement. It was settled in 1871 and incorporated as a town in 1879 and as a city in 1883. It is governed by a mayor and two commissioners. Pop. (1940) 3,185, (1950) 2,952.

CHERRYVILLE, chër'i-vîl, town, North Carolina, in Gaston County, 10 miles northeast of Shelby. Its industries are cotton milling, and machinery. Pop. (1950) 3,492.

CHERSKOGO RANGE, chër-skô'vû, mountain range, Soviet Russia, in the northeastern part of the Yakutsk Republic, Asia.

CHERSO. See CRES.

CHERSONESE, kûr'sô-nêz, The (Greek, peninsula). This name has been given to several peninsulas: (1) CHERSONESUS CIMBRICA, now Jutland, Denmark; (2) TAURICA (ancient CHERSONESUS), the peninsula formed by the Black Sea and the Sea of Azov—the Crimea; (3) THRACICA CHERSONESUS, the great peninsula in Thrace, now Gallipoli Peninsula; (4) CHERSONESUS AUREA or GOLDEN CHERSONESUS, in India beyond the Ganges, the Malay Peninsula.

CHERT, a cryptocrystalline (not visibly crystalline) variety of quartz closely related to flint, but less translucent and having a more splintery fracture. In geology the term is applied to a considerable range of siliceous rocks, from the impure flints largely formed from the siliceous remains of organisms, sponges and diatoms, found in limestones and other stratified rocks, to the jaspered quartz formed by the alteration of limestones or limy sandstones.

CHERTSEY, chûrt'sî, town, England, in the county of Surrey, 22½ miles southwest of London, on the London and Southwestern Railway, is pleasantly situated on the right bank of the Thames, over which there is

an 18th-century bridge. Charles James Fox lived nearby for a time and Abraham Cowley spent here the last years of his life. Of the great Benedictine monastery, founded in 666, only the ground plan is now traceable; the Abbey fell into decay in the 17th century. Noted in the Middle Ages for its fairs, Chertsey is a busy market town for garden produce shipped to London; it has manufactures of electrical equipment. Pop. (1951) 31,029.

CHERUB, chër'üb (pl. CHERUBIM), one of the order of heavenly beings (see ANGELS) which in the angelic hierarchy are next to the seraphim. Originally, in Mesopotamia, the word referred to a winged sphinx with human head and animal body, placed at the entrance of sanctuaries and palaces as divine intercessors and guardians. Their use in Hebrew religion came from that of the Canaanites. (See II Samuel 22:11, I Kings 6:23, I Chronicles 28:18, Ezekiel 28:14, Psalms 18:10, Exodus 25:20, where they now symbolize the power and majesty of Israel's God, Yahweh.) In the New Testament (Revelation 4:6) the four "Living Creatures" are derived from later Jewish apocalyptic literature, all of which derived this feature from Ezekiel 1:4-28.

Consult Charles, R. H., *Commentary on the Revelation of St. John*, vol. 1, pp. 118-123 (New York 1920).

FREDERICK C. GRANT,
Union Theological Seminary.

CHERUBINI, kār'ōō-bē'nē, **Maria Luigi Carlo Zenobio Salvatore**, Italian composer; b. Florence, Sept. 14, 1760; d. Paris, March 15, 1842. At 13 he had written a mass and other sacred music, and between 1780 and 1784 he wrote 7 operas, which were performed in various cities of Italy. In 1784 he was invited to London, where he wrote for the King's Theatre *La Finta Principessa* (1785), which was well received, and the less-successful *Giulio Sabino* (1786). He received there the title of court composer. In 1786 he moved to Paris. The opera *Ifigenia in Aulide* was first performed in Turin in 1788, and that same year the Paris Opera staged *Démophoon*. His operas—*Lodoiska* (1791), *Elisa* (1794), *Médée* (1797)—succeeded one another at a fast pace, showing progress toward broader forms and more complex orchestration. The musical comedy *Les deux Journées*, first performed in Paris in 1800, gained great popularity in Germany and Austria under the title *Der Wasserträger*. In 1795 Cherubini was named inspector of the Paris Conservatoire, a poor post for his talents; this was due to Napoleon's dislike for him because of a sarcastic remark on the emperor Cherubini had once made. During his sojourn in Vienna, where he produced *Faniska* (1806), he met Ludwig van Beethoven, who greatly admired his work. After his return to Paris, Cherubini resolved to give up music and retired to the castle of the prince of Chimay. His friends later convinced him to produce a composition for a local religious festival: he wrote the great *Mass in F* for three voices and orchestra. From now on he devoted more and more of his time to liturgical compositions, although he did not give up opera entirely—his last one, *Ali Baba*, being produced in 1833. His religious works include 10 masses, the great *Requiem in D Minor*, a Te Deum, litanies, etc. He also excelled in chamber music: his six string quartets and his quintet are still performed. In 1822

Cherubini was made permanent director of the Paris Conservatoire. His *Treatise on Counterpoint and Fugue* became a classic and was translated in several languages.

Consult Bellasis, E., *Cherubini: Memorials Illustrative of His Life* (London 1874); Crowest, F. I., *Cherubini* (London 1890).

CHERUEL, shā'rū-ël, **Pierre Adolphe**, French historian; b. Rouen, Jan. 17, 1809; d. Paris, May 1, 1891. He taught at Rouen and in Paris, and later was rector of the academy at Strasbourg, then at Poitiers. Of interest are his *Dictionnaire historique des institutions, mœurs et costumes de la France* (1855), and his three essays on the Duc de Saint Simon. On Mazarin whose letters he also published, he wrote *Histoire de France pendant la minorité de Louis XII* (1880) and *Histoire de France sous le ministère de Mazarin* (1883).

CHERUSCI, kê-rūs'i, people of Germany mentioned in Caesar's *De bello gallico* as living next to the Suevi, between the Elbe and Weser rivers. As one of the strongest and most numerous of Germanic tribes, they played a prominent role in the resistance against Rome. They were submitted by Drusus and Tiberius, but continued to exert a sort of hegemony over the smaller Germanic tribes. In the general uprising against Rome a few years later their great leader Arminius (q.v.) won a decisive victory over Varus and his legions in the Teutoburg Forest (9 A.D.). In 16 A.D. however, Germanicus indicated Varus' defeat. Internecine warfare and the struggle against Rome and the neighboring tribes greatly weakened the Cherusci, who had to yield their prominent position to the Chatti. In Tacitus' times they had already lost their importance.

CHERVEN BRYAG, chër'ven bri-äk', city, Bulgaria, in Pleven district, 5 miles north-north-west of Lukovit, on the Panega River. The city is an agricultural center and rail junction. Pop. (1946) 5,268.

CHERVIL, name applied to two kinds of herbs grown in the vegetable garden, both belonging to the Umbelliferae or parsley family, native of Europe. Salad chervil (*Anthriscus cerefolium*) is an annual herb, of simple culture, the sweet-scented leaves used like parsley for garnishing and for flavoring soups and stews. Also called curled chervil, it is chiefly grown as a spring or fall crop, since it does not thrive well during the summer. It does best in rich, well prepared soil. Similar to curled parsley but of more delicate texture, its leaves bright rich green, finely divided and curled, chervil has a pungent, aromatic flavor. The black seeds produce seedlings two to four weeks after planting, and the leaves are ready for use in eight to ten weeks after the seed is sown. Plants produce a rosette four to five inches tall, with a spread of 10 to 12 inches, and later a branched flowering stem, commonly 15 to 18 inches tall. Turnip-rooted or tuberous chervil (*Chaerophyllum bulbosum*) is a hardy biennial, producing carrot-like small gray or blackish edible roots, eaten either like beets, or used as flavoring for soups and stews. Since its seeds lose their vitality very quickly, they should be sown in the autumn (as soon as the seeds are ripe), or else stratified until spring. The cultivation resembles that of carrots.

CHESAPEAKE AND DELAWARE CANAL, connecting Chesapeake and Delaware bays. Its overall length, including approaches, is 19.1 miles, although the actual distance from bridge to bridge is 14 miles. See **CANALS**.

CHESAPEAKE AND LEOPARD, Affair of the, June 22, 1807. *Chesapeake* was a 38 gun frigate destined to relieve the *Constitution* in the Mediterranean. Capt. James Barron was to go out in her as commander of the Mediterranean squadron. She had been refitted at the Washington Navy Yard, and made final preparations at Norfolk, reporting ready for service on June 19. On the 22d she got under way, but expecting no attack from powers at peace with this country, was in no shape for immediate action, and being four months behind time, could not wait. The gun deck was obstructed with various lumber, sick seamen were lying on the upper deck, the cables were not stowed away, the powder horns were not filled and the crew was raw and not exercised at the guns. At this time, in the heart of the Napoleonic wars, the high wages and relatively safe employ of the American merchant and even naval service, with the rights of American citizenship immediately obtained, raised the normal rate of desertion from the British Navy so much that its officers were much embarrassed and greatly incensed; and Great Britain claimed, as for many years afterward, the right of searching neutrals for deserters and contraband. At the same time, her press gangs crimped for service any strays who could be caught, of any nationality, and rarely gave any redress. Early in 1807 a British fleet lay off Norfolk watching to intercept some French frigates in the Chesapeake; and a boat's crew deserted bodily and escaped to Norfolk. The captain was told that they had enlisted on the *Chesapeake*—which was true of only one, and he under an assumed name; and meeting the latter and another deserter in the streets of Norfolk, was defied. Another vessel, the *Melampus*, reported three deserters gone to the *Chesapeake*, but it was proved that they were native Americans illegally pressed. Admiral Berkeley, at Halifax, on complaint of his officers, ordered any of his vessels to overhaul and search the *Chesapeake* on meeting her outside the United States jurisdiction. The order was carried out by the 52-gun flagship, *Leopard*. Captain Humphreys, after consulting with the local commandant at Lynnhaven, followed the *Chesapeake* out beyond Cape Henry, hailed her, and sent a boat with a copy of Berkeley's order. Barron, who believed that he had no deserters aboard except the *Melampus*, which were not really such, honestly denied having any, but refused the right to search; the messenger lieutenant at once left and within five minutes the *Leopard* came closer, and Humphreys announced that he should carry out his orders. Barron at once called his men to quarters, and did everything that skill, coolness and courage could do to prepare for action, but the *Leopard* almost at once poured one whole broadside into the *Chesapeake*, and then two more in rapid succession, without the possibility of her opponent replying. Three of the latter's men were killed, Barron and 17 others wounded, and it was certain that the vessel would be sunk in a short time if the fire kept up, and Barron, to stop a useless

massacre, struck his flag. The one English deserter was hunted out and hanged, the three Americans taken and imprisoned. The mass of the country was on fire with indignation; the extreme Federalists at first justified the English course, but were compelled by public feeling to exhibit some patriotism. Even Jefferson, whose unwise course had brought on the catastrophe, interdicted British cruisers from American ports, and demanded disavowal and reparation from Great Britain, which were not given; but he did nothing to prevent the recurrence of such outrages. The unfortunate Barron, who had behaved like a brave man and good officer, and whose instructions had bound him to do nothing to bring on collisions, was made the scapegoat of the popular fury. His own captain screened himself by accusing him, and a court-martial on board his own vessel from Jan. 4-8, 1808, Capt. John Rodgers president, after acquitting him of all blame in every respect but one, found him guilty in not preparing for action as soon as he read Admiral Berkeley's order, and sentenced him to five years' suspension without pay or emoluments. The gross injustice of this is now admitted. One of the judges was Stephen Decatur (q.v.), who never ceased reflecting on Barron till the latter challenged and killed him.

CHESAPEAKE AND OHIO RAILWAY COMPANY, The, a railroad which had its origin in the charter of a company by the legislature of Virginia on Feb. 18, 1836, to build through the county of Louisa, Va., to the eastern base of the southwest mountains in Virginia, and was styled The Louisa Railroad Company. Under this title construction was completed from Hanover Junction (now Doswell, Va.) to Shadwell, Va., 64.50 miles (1836-1850). Operation was by the Richmond, Fredericksburg and Potomac Railroad Company until 1847. As of Feb. 2, 1850 the name of the Louisa road was changed to the Virginia Central Railroad Company. Construction was completed into Richmond, Va., from Hanover Junction in 1851. Westward the road was extended and operated in short sections reaching Jackson River, approximately two miles west of the present Clifton Forge, Va., by 1857; with an approximate mileage of 292 miles. Of this mileage 16.81 miles through the Blue Ridge Mountains was built by the State of Virginia and incorporated in 1849 as The Blue Ridge Railroad Company. Virginia Central and Chesapeake and Ohio operated this property until it was acquired by Chesapeake and Ohio in 1870. The Virginia Central was built to Covington, Va., in 1868.

In 1853, the state authorized the construction of the Covington and Ohio Railroad, from Covington, Va., to the Ohio River. After about \$3,000,000 was expended with no line completed, work was stopped by the War Between the States. When the war ended, the state having been dismembered, Virginia and West Virginia united in efforts which resulted in combining the Virginia Central and the Covington and Ohio Railroad Company in 1868 under the corporate name of Chesapeake and Ohio Railroad Company. Completion of the road westward to Huntington, W. Va., on the Ohio River, was achieved in 1873. In 1878 the road was sold under foreclosure and reorganized as The Chesapeake and Ohio Railway Company.

Under legislative authority, the road was extended from Richmond to Newport News, Va., operating as of 1882, and to Fort Monroe in 1890. In the meantime it had been built from Huntington to the Big Sandy River, the western boundary of West Virginia, where it established connection with the Elizabethtown, Lexington and Big Sandy Railroad Company in October 1880, opening up through service to Lexington, Cincinnati and the west and south. In 1888 the road was again reorganized, forthwith securing control, through stock ownership of the Maysville and Big Sandy Railroad Company and the newly built bridge at Cincinnati, of operation into Cincinnati, with an approximate mileage from Newport News to Cincinnati of 664 miles.

In 1892, the Elizabethtown, Lexington and Big Sandy Railroad Company, extending to Lexington, Ky., was acquired, and in 1895 through service to Louisville, Ky., was established by an agreement with the Louisville and Nashville for the joint use of its line from Lexington to Louisville.

The Richmond and Alleghany Railway Company, located in the James River Valley, operating the 230 miles between Richmond and Clifton Forge, Va., was conveyed to Chesapeake and Ohio in January 1890, thereby affording a low-grade route to tidewater for the company's heavy coal tonnage. Through acquisition of the Richmond and Alleghany and allied canal properties Chesapeake and Ohio established its original antecedent as The James River Company (canal and turnpike), incorporated 1785, with George Washington as first, though inactive, president.

Chesapeake and Ohio's entrance into Washington, D.C., was secured in 1891 under lease and trackage agreements for the joint use of tracks of the Virginia Midland Railway Company (now Southern Railway Company) and the Washington Southern Railway Company. (A number of subsidiary lines and branches had been built or acquired penetrating mineral and timber regions. Among these were the Big Sandy in Kentucky; the Guyandot Valley; Coal River; Cabin Creek; Paint Creek; Gauley; Loup Creek; Piney Creek; the Greenbrier, in West Virginia and branches in Virginia.)

In 1910 the Chicago, Cincinnati and Louisville Railway Company was purchased under foreclosure proceedings and reorganized as The Chesapeake and Ohio Railway Company of Indiana, the property of the latter being acquired in 1934. This afforded an outlet to Chicago and Lake Michigan.

To obtain a connecting link with the Hocking Valley Railway Company, controlled through stock ownership as of 1910, the Chesapeake and Ohio Northern Railway Company caused to be constructed 30 miles between Limeville, Ky., and Waverly, Ohio, in 1917, and the Chesapeake and Hocking Railway was constructed in 1927, a distance of 63 miles between Greggs and Valley Crossing, Ohio. The properties of these two companies were acquired in 1921 and 1930, with the Hocking Valley and Chesapeake and Ohio being merged as of 1930, thereby giving the Chesapeake and Ohio the much desired main line operation to Toledo and the Great Lakes.

Stock control of the Pere Marquette (PM) was acquired in 1929. The plan of consolidation announced by the Interstate Commerce Commission in 1929, and modified in 1932, provided for a Chesapeake and Ohio-Nickel Plate System.

This was delayed. Robert R. Young, Chairman of Chesapeake and Ohio's Board of Directors as of 1942, continued the plans for a C&O, NKP and PM merger. With NKP stockholders and directors in control as opposed, NKP was dropped and in 1946 C&O and PM signed an agreement of merger. This was consummated June 6, 1947. The two lines are identified as the Chesapeake District and the Pere Marquette District of The Chesapeake and Ohio Railway Company.

The eastern termini of the Chesapeake and Ohio are Washington, D.C., Newport News, and (by ferry transfer) Norfolk, Va. From these places it extends westward, passing through the agricultural, and historical tidewater and Piedmont regions, crossing the Blue Ridge Mountains and the Shenandoah Valley of Virginia, thence through the iron ore regions, across the Alleghany Mountains to and through the coal and timber fields of West Virginia to the Ohio River, at Huntington. One of its lines continues along the Ohio River within the north boundary line of Kentucky to Cincinnati, Ohio, and thence across Indiana to Chicago; another extends from Ashland, Ky., through the Blue Grass region to Louisville, Ky., and another northward to Lake Erie at Toledo. From Toledo over the Pere Marquette District the system serves Detroit, Flint, Lansing, Saginaw, Grand Rapids, Chicago, Milwaukee; two other Lake Michigan ports in Wisconsin through its fleet of modern car ferries; a prosperous and industrial territory in Ontario; and one in the vicinity of Buffalo, N. Y.

The Pere Marquette Railway Company was a combination of something over forty individual Michigan railroad companies which, prior to 1900, had been merged into three small systems—the Flint and Pere Marquette Railroad Company, the Chicago and West Michigan Railroad Company, and the Detroit, Grand Rapids and Western Railroad Company. In 1903 this mileage was increased by the acquisition of The Lake Erie and the Detroit River Railroad Company, in Canada, a line which runs easterly from Windsor and is reached by car ferry operation over the Detroit River.

The Flint and Pere Marquette Railroad Company was probably the pioneer of all of the companies, the consolidation of which went to make up the Pere Marquette Railway Company. That company filed its articles of association in 1857 and operations began in 1862. The 170 miles from Flint to Pere Marquette (now Ludington) required 17 years to build. Michigan was then timberland, with construction through heavily timbered forests, with rivers to cross and grades to subdue. Most of the 40-odd railroads later merged with Pere Marquette were built during the big timber days.

In 1890 the Flint and Pere Marquette effected an entrance into Detroit. Prior to 1897 freight carried to Ludington, destined to Wisconsin points, was unloaded from the freight cars and transferred to boats for transportation across Lake Michigan. In 1897 a car ferry was constructed which was capable of carrying 30 small freight cars across the lake, and so, in effect, the rails of the Flint and Pere Marquette were extended across Lake Michigan. From this beginning came the modern car ferry service of the Pere Marquette District today. An airplane

view of the Marquette District would show two lines of railroad spanning Michigan from west to east: one line running from Ludington on the west coast, through Saginaw and Detroit to the Toledo Gateway, with a fork from Saginaw to Port Huron on the east coast; the other line from Chicago, in the State of Illinois, through Grand Rapids to Detroit, with a line branching out from Grand Rapids and running north to Petoskey near the Strait of Mackinac, and one north to Saginaw. The Canadian line, through the medium of car ferries operating on St. Clair and Detroit rivers, not only lengthens the haul to Buffalo but with car ferry operations on Lake Michigan, provides a short route between the northwest and the Atlantic seaboard. WALTER J. TUOHY,
President, The Chesapeake and Ohio Railway Company

CHESAPEAKE AND SHANNON, Battle of, June 1, 1813. In the War of 1812, the former vessel (See CHESAPEAKE and LEOPARD, AFFAIR OF THE), cruised to no purpose from December 1812 till April 1813, and arrived at Boston, April 9. Her captain, Evans, left her on account of ill-health, and about the middle of May was replaced by Capt. James Lawrence, famous for the brilliant victory of the *Hornet* over the *Peacock*. He accepted against his will; nearly all the officers and crew were new, and the latter second-rate, totally untrained and glibly over questions of prize money. On May 25 Captain Broke of the *Shannon*, lying outside, sent away his consort, the *Tenedos*, to have a fair chance to fight the *Chesapeake* alone, and repeatedly urged Lawrence to arrange a duel between the ships. In theory they were evenly matched; they were of almost exactly the same length; the *Chesapeake* now carried 50 guns, the *Shannon* 52; the *Chesapeake* had 379 officers and crew against the *Shannon's* 330, but the latter had been trained for seven years under Broke himself, kept in constant artillery and other practice, and was a thoroughly disciplined fighting machine, men used to each other and the officers. On June 1, however, Lawrence sailed out to meet his enemy, and at 5.30 p.m. they engaged. After a couple of broadsides, the *Shannon's* shot cut the *Chesapeake's* stays, and the latter drifted helplessly stern foremost toward her adversary. There was no salvation but to make sail forward or to board, and both were impossible. The *Shannon's* broadsides and the musketry fire from her tops swept the *Chesapeake* diagonally from stern to stern, without the latter being able to fire a shot in reply, beating in the stern ports and killing or wounding every man on the quarter-deck and the after part, including the men at the wheel. Just before the vessels struck, Lawrence ordered up his boarding party; but almost at the same instant he fell mortally wounded by a musket ball, and was carried below. Not a living person was on the quarter-deck, and Broke, with 50 boarders, rushed on board unresisted just as the vessels parted. So fierce was the resistance from that 30 or so of the American crew who had rallied at the fore-castle, that 37 of the boarding party were killed or wounded, including Broke himself. The *Chesapeake* lost 61 killed and 85 wounded; the *Shannon* 33 killed and 50 wounded. The former was

towed into Halifax as a prize, turned into a British war vessel and in 1820 was broken up.

CHESAPEAKE BAY, in Maryland and Virginia, and dividing the former state into two parts, is the largest inlet on the Atlantic coast of the United States, being 200 miles long and from 4 to 40 miles wide. Its entrance, 12 miles wide, has on the north Cape Charles, and on the south Cape Henry, both promontories being in Virginia. The bay has numerous arms, which receive many navigable rivers such as the Susquehanna on the north, the Potomac, Rappahannock and York on the west, and the James on the southwest. Extensive oyster beds are to be found in this bay; and game fowl are plentiful.

CHESAPEAKE BAY DOG. See Dog.

CHESELDEN, chës'el-dën, William, English surgeon and anatomist: b. Somerby, Leicestershire, Oct. 19, 1688; d. Bath, April 10, 1752. At the age of 22 he began to give lectures on anatomy, and in 1712 he was chosen F.R.S. In 1713 he published a treatise on the *Anatomy of the Human Body*, long a favorite manual of the science. He continued to read his lectures for more than 20 years, during which he gradually rose to the head of his profession. In 1723 he published a *Treatise on the High Operation for the Stone*; in 1727 was appointed surgeon to Queen Caroline. One of the greatest British surgeons, he once performed his celebrated operation for the stone in 54 seconds. His *Osteographia* was published in 1733.

CHESHIRE, or **CHESTER**, England, a maritime county, bounded by seven other counties in England and Wales, by the estuaries of the Dee and Mersey and by the Irish Sea. Its area is 1,026 square miles, of which the greater part is under cultivation. The surface is generally level, the soil mostly a rich reddish loam variously clayey or sandy. There is some of the finest pasture land in England; and cheese, the main product of the Cheshire farmer, is made in great quantities. Extensive tracts of land are cultivated as market gardens, the produce being sent to Liverpool, Manchester and other cities. Minerals abound, especially rock salt and coal, which are extensively worked. Cotton manufacture is carried on at Stockport, Stalybridge and in the northeastern district, shipbuilding at Birkenhead and other places. There are numerous railroad lines and a splendid system of canals, among them the famous Manchester Ship Canal. The various divisions of the county return nine members to the House of Commons. Pop. (1938) 729,400.

CHESHUNT, chës'ent, England, town in Hertfordshire, seven miles south of Hertford, and 14 miles north of London, on the Lea. From 1792 to 1905 it was the seat of Cheshunt Theological College. Pop. (1938) 16,940.

CHESNEY, chës'nî, Charles Cornwallis, English soldier and author: b. near Kilkeel, Down, Sept. 29, 1826; d. March 19, 1876. He was a well-known military engineer, but was still better known as a writer on military themes, publishing *Campaigns in Virginia and Maryland* (1863); *Waterloo Lectures* (1868); and *Essays in Military Biography*. (1874).

CHESNEY, Francis Rawdon, British soldier and explorer: b. Annalong, County Down, Ireland, March 16, 1789; d. Mourne, Jan. 30, 1872. Designated for a military career, he became a cadet, and in 1805 was gazetted to the royal artillery. On a tour of inspection in Egypt and Syria in 1829-1831 he proved the Suez Canal to be a feasible project, and on the strength of his report Ferdinand Marie de Lesseps undertook the great enterprise. At the same time he developed a plan for the opening of a route to India through Syria and the Persian Gulf, and headed two expeditions to the Euphrates River. The first, in 1835, proved that the Euphrates was navigable for steam vessels from a point about 120 miles from the Mediterranean to the Persian Gulf. The second expedition, in 1856, had the purpose of examining the possibilities of a railway through the Euphrates valley. The result was highly satisfactory, but the plans were never realized. He became a general in 1868.

Chesney published *Expedition for the Survey of the Rivers Euphrates and Tigris* (1850); *A History of the Past and Present State of Firearms* (1852); and *Narrative of the Euphrates Expedition* (1868).

CHESNEY, Sir George Tomkyns, British Indian Army officer and author: b. Tiverton, England, April 30, 1830; d. London, March 31, 1895. Wounded in the assault on Delhi (1857), he had a brilliant army career, attaining the rank of full general in 1892, when he was also elected to Parliament. He planned the Royal Indian Civil Engineering College at Cooper's Hill, Staines, and returned from India to serve as its first president in 1871. That year he contributed to *Blackwood's Magazine* his famous skit, "The Battle of Dorking, or Reminiscences of a Volunteer," republished in pamphlet form and translated into many languages. It described an imaginary German invasion and conquest of England, and was the prototype of the many warning novels issued in England on the eve of World Wars I and II. The keynote of his novel *The True Reformer* (1874) was army reform. Other novels include *The Dilemma* (1876) and *The Private Secretary* (1881).

CHESNUT, chēs'nūt, Victor King, American chemist and botanist: b. Nevada City, Calif., June 28, 1867; d. August 1938. Upon graduation from the University of California in 1890, he pursued postgraduate work at the University of Chicago and Columbia (now George Washington) University, Washington, D.C. In 1894-1904 he was assistant botanist in charge of the poisonous plant investigations carried out by the Bureau of Plant Industry, United States Department of Agriculture. From 1907 to 1916 he was assistant chemist of the division of drugs and from 1924 to 1933 associate chemist of the department's Bureau of Chemistry.

His works include *Principal Poisonous Plants of the United States* (1898); *The National Museum in Drug Research* (1908); and several monographs on the odorous constituent in different fruits and plants.

CHESNUTT, Charles Waddell, American Negro educator and lawyer: b. Cleveland, Ohio, June 20, 1858; d. there, Nov. 15, 1932. While still a child he was taken to North Carolina where he was educated at the State Normal

School at Fayetteville, of which school he became principal in 1881. Later he removed to New York City, where he practiced journalism while studying law. Returning to Cleveland, he was admitted to the Ohio bar in 1887.

He is best known as the author of *The Conjure Woman* (1899); *The Wife of His Youth and Other Stories* (1899); *Life of Frederick Douglass* (1899); and *The Colonel's Dream* (1905).

CHESS, chēs, a game for two contestants, played on a square board consisting of 64 squares of alternating colors, arranged in 8 rows of 8 squares apiece. Each contestant has 16 chessmen of 6 different designs, which he moves on the board in accordance with prescribed procedures. Since the board is the same as that for checkers (q.v.), the two games are often compared and contrasted; there are, however, fundamental differences.

The date of origin of chess is disputed by various researchers. Some consider that it was known as far back as Homer's time. More maintain that the game was not developed until some 600 years after the start of the Christian era. Other students hold that the time of its birth cannot be fixed, since it was evolved from much older games. Most authorities agree that its roots probably stem from remote antiquity in India, undergoing along the way many alterations. The last changes governing the moves and rights of the different chessmen were made in Europe in the 16th century. Since then the game has remained unchanged, except for tournament rules.

Chess is played in all civilized countries, and its great popularity has made it one of the most generally permitted recreational activities among prisoners of war.

Chessmen and Their Moves.—The chessboard and the location of the different kinds of chessmen at the beginning of a game are illustrated in the accompanying diagram.

The opponents in a chess game are customarily designated as "white" and "black." Each contestant has 8 "pieces," as they are called, on the row nearest him, consisting of 1 king, 1 queen, 2 bishops, 2 knights, and 2 rooks; and in front of the pieces a row of 8 "pawns." The board should always be set up in such a position that there is a single "white" square at the near right-hand corner of each player. The squares on many boards are of other colors than black and white, but technically the lighter ones are considered "white" and the others "black."

White always moves first, then the moves are taken alternately. The legal moves of the pieces and pawns are as follows:

KING—One square only, forward, backward, to either side, or diagonally.

QUEEN—Any number of squares, forward, backward, to either side, or diagonally.

ROOK—Any number of squares, forward, backward, and to either side.

BISHOP—Any number of squares diagonally. Hence a bishop may never be on a square of different color from that on which he started.

KNIGHT—This is the only chessman which does not travel in a simple move, either forward, or backward, or to the side, or diagonally, but has a peculiar movement that combines 2 steps (squares) forward, backward, or to either side, and thence 1 step (square) to either side.

PAWN—Only straight forward, 1 square at a time, except for its first move which may be of 1 or 2 squares at the player's option.

In addition to the different movements, some chessmen have other powers and limitations:

Left: Chessboard, as it appears at the start of a game, with the 32 pieces in their original positions, illustrated by their conventional symbols. Right: Corresponding diagram showing the standard abbreviations for the names of the pieces, with the rows numbered for the purpose of designating the squares. Thus: the square marked X is White's K14, while it is also Black's KB5.

BLACK

8	QR	QK1	QB	Q	K	KB	KK1	KR	1

1	QR	QK1	QB	Q	K	KB	KK1	KR	8

WHITE

(1) Any of the pieces may capture an opposing piece or pawn located on any square to which it legally moves, thereby causing removal of the opponent's man from the board.

(2) A pawn captures only by moving 1 square diagonally forward to its right or left. The French term *en passant* is applied to the following capturing privilege of the pawns. When, for example, a black pawn has advanced to a position where a white pawn's first move of 2 squares brings the two pawns side by side on the same row, the black pawn may capture this white one by moving forward diagonally 1 square into position behind the white pawn.

(3) If a pawn reaches the last row nearest the opponent, the owner may exchange it for any piece.

(4) A knight's move is not impeded by the presence of other men on intervening squares; in effect, it leaps over them. No other piece (or pawn) may move over an occupied square, but may move onto it if that square is occupied by an opponent's chessman, thus capturing the latter.

(5) The king and either rook together have a special right, called "castling" because "castle" was an earlier name for the rook. Castling can be applied only once by each player during a game, and consists of the following movement: The king is moved 2 squares toward the rook, which then leaps over the king laterally to the adjoining square. This is the only time during a game of chess that a player may move 2 chessmen at the same time. Castling is possible only if neither king nor rook has been previously moved, if there is no other chessman between king and rook, and if the king is not in check and does not have to move over a square that is threatened by an opponent's man.

Check and Checkmate.—The king can never be captured. It can never move into a position where an opponent's man could capture it in one move, that is, move into "check." If the aggressor puts the opposing king in check, he must state so, saying "Check!" The endangered king must be brought "out of check" by moving the king, by capturing the attacking man, or (except in the case of check by a knight) by interposing one of its own men. If it is impossible to bring the king out of check, it is "checkmated," and the game is won by the opponent.

Capturing the opponent's men and outmaneuvering him in position are the two main devices available for winning the game. Besides games which result in a checkmate—hence victory for one or the other player—there are "drawn games," or ties. Very often games among the greatest players produce a surprising percentage of draws. (In a match between José Raoul Capa-

blanca and Alexander Alekhine in 1927, out of 34 games no less than 25 were draws.) A draw may result from several factors:

(1) Inadequate forces: This is the case when the men left on the board are insufficient to assure the power of one player to force a checkmate.

(2) Perpetual check: This applies if a position is attained where one player may repeatedly check the opponent's king as often as he wishes without being able to force a checkmate.

(3) Stalemate: This results from a situation where a king is not in check, but where its player cannot make a move without putting it in check.

A draw may also be claimed in no fixed time acceptance of the claim between the players.

Notation and Competitions.—In order to express the moves of chessmen on the board in writing, for example for textbooks, newspapers, magazines, and long-distance games, as well as to chronicle the games of a tournament, a special mode of notation has been adopted. The chessmen are indicated by abbreviations; in the case of two pieces with the same name, they are distinguished as king's or queen's pieces in conformity with their original positions on the king's or the queen's side.

King	K	Queen	Q
King's bishop	KB	Queen's bishop	QB
King's knight	KKt	Queen's knight	QKt
King's rook	KR	Queen's rook	QR

Each pawn is indicated by relation to the piece in front of which it stood at the beginning of the game. The pawn in front of the queen's bishop, for instance, is called the queen's bishop's pawn, though it is represented merely with the symbol P, since it is easy to keep track of the pawns.

Also clearly identified are the squares of the board: The rows extending horizontally from the left to the right, with the board in playing position, are called ranks. Those extending vertically between the two players are called files. Each file is designated according to the piece originally posted on its first rank (again distinguished by the prefix K or Q if necessary), and the ranks are numbered from 1 to 8, each player counting from his side.

If, therefore, "white's" first move advances the king's pawn 2 steps, it would be described

as follows: P—K4; and accordingly, KKt—B3 would indicate that the king's knight moved to the 3d square in the (king's) bishop's file (since it could not have moved to the queen's bishop's file, the prefix K can be left out).

A succession of moves is therefore chronicled in this fashion:

White	Black
1. P—K4	1. P—K4
2. KB—B4	2. KB—B4
3. Q—K5	3. KKt—B3
4. Q takes BP (checkmate).	

A capturing move may be indicated by the symbol X, while the following sign may be used for castling: O—O if the king's rook is involved, and O—O—O for castling with the queen's rook. To mark the best move, (!) is sometimes used; for a weak one, (?).

Many experts can keep in mind the exact situation in a number of games played simultaneously. The featured star usually goes from table to table, making his moves after having seen the opponent's move, while the latter has time to ponder his move until the star returns. In other cases a great player may even play blindfolded, being told which moves the opponents have made, and indicating his moves in code. Up to 45 games have been played blindfold and simultaneously by great masters of the game. Almost invariably in such a contest, the featured star wins appreciably more games than he loses, and to score a draw against him is usually considered a moral victory by his little-known opponents.

We know the names of many brilliant chess-players, especially in Italy, France, and Spain, as far back as 1500 A.D., but with the first international chess tournament in London in 1851, the era of the "world champions" began. The winner of that tournament, Professor Adolf Anderssen of Germany, was recognized as the world's greatest player, and when he was defeated in 1866 by the Austrian player, William Steinitz, the latter claimed the title of world champion. Subsequently other stars of various nations rose to fame. Such masters of chess as Paul Charles Morphy, Harry Nelson Pillsbury, Emanuel Lasker, Alexander Alekhine, Siegbert Tarrasch, and José Raoul Capablanca, to name some of the outstanding ones, have competed in international tournaments.

Highest ranking among American players were doubtlessly P. C. Morphy (1837–1884), the first United States champion, and Frank James Marshall (1877–1944), who is said to have been unable to make an ordinary move if he could see an unusual one that bore the slightest promise of success.

Hints on Play.—Throughout the literature on chess, strategy and tactics are treated under three broad divisions: openings, mid-game tactics, and end-game play; but since the variety of possible moves is immense, the multitude of theories on chess is equally great. However, some of the fundamental principles, helpful to every beginner, may be briefly summarized:

(1) At all stages the player should plan ahead, giving heed to both his attack on the opponent and the defense against the opponent's campaign as it develops.

(2) A player should not stress the mobilizing of his "big" pieces (the rooks and the queen, as distinguished from the "small" bishops and knights) too early.

(3) Pawns should be moved so as to protect one another and their pieces. It is most important that the player should keep two or three in position to protect the king.

(4) As a rule, one should castle early. It serves two

purposes: to guard the king, and to bring the rook into a useful position.

(5) In order to improve his "chess thinking," a player should study the different openings, mid-game tactics, and end-game plays given in all sound books on chess.

(6) Solving chess problems and reconstructing famous games, trying to analyze every movement, is indispensable for a player who wants to succeed.

Chess has always attracted the interest of various people with different talents, and some curious products resulted:

A sensation was created when the Austrian mechanic Wolfgang von Kempelen (1734–1804) introduced his "Automaton," a picturesque figure of a Turk seated at a chessboard. This figure could play as any human being, and was thought to be entirely mechanical. Later exposed, it was shown that a very skillful player was concealed inside the base upon which the ensemble was erected; this player, by a very ingenious device, could operate the figure on top.

Another remarkable feature of chess consists of mammoth games with costumed human beings as chessmen. The largest-scale game of this kind is said to have been played in Stockholm, Sweden, in the late 1890's on a board of 4,305 square feet.

At all times master craftsmen have devoted their work to the creation of elaborate sets—precious pieces of art—using such materials as bone, ivory, rare woods, mother of pearl, gold, and jewels.

SHEPARD BARCLAY.

Bibliography.—The earliest book on chess was *Liber de Moribus Hominum et Officiis Nobilium Super Ludo Scacorum*, written before 1300 by the Italian Dominican friar Jacobus de Cesolis. The book was later translated into several European languages, and in 1474 William Caxton translated it from a French version and printed it in 1479 under the title *The Game and Playe of Chess*, one of the earliest incunabula in English. Other works include: Capablanca, J. R., *Chess Fundamentals* (London 1942); Fine, Reuben, *Chess the Easy Way* (New York 1942); Lasker, Emanuel, *Manual of Chess* (New York 1947); Reinfeld, Fred, *The Treasury of Chess Lore* (New York 1951); and Hollings, F., *The Beginner's Book of Chess* (New York 1953).

CHEST, in man and the higher vertebrates the cavity formed by the breast bone or sternum anteriorly, the ribs and spine laterally and posteriorly. The diaphragm separates it from the abdominal cavity below. It contains such vital organs as the heart (within the mediastinal cavity), the great vessels of the heart, the lungs, the trachea or windpipe and its branches the bronchi, many important nerves and ducts, and the esophagus or gullet. Diseases affecting the organs of the chest are many, while chest deformities are encountered often, as a result of pulmonary and pleural infections, infantile paralysis (poliomyelitis), postural scoliosis, and congenital malformations. See also **ANATOMY**, **COMPARATIVE**; **DISEASE**; **HEART**; **LUNGS**; **THORAX**.

HAROLD WELLINGTON JONES, M.D.,
Editor, "Blakiston's New Gould Medical Dictionary."

CHEST, a large box of wood or metal with a hinged top. Chests have always been widely used and were part of the earliest furniture almost everywhere. Mainly used as a receptacle for clothes and valuables, the chest in former days served sometimes as seat, table, or even bed. Used by the rich of the Middle Ages as a portmanteau, it was sometimes covered with leather. Like other furniture, chest designs changed with the architecture; craftsmen of all epochs have decorated them with paint or wood-carving, chisel-

ing or inlay, according to the current style and the material used.

CHESTER, Colby Mitchell, American naval officer: b. New London, Conn., Feb. 29, 1844; d. Rye, N. Y., May 4, 1932. He graduated at the United States Naval Academy in 1863, and in the American Civil War served at the Battle of Mobile Bay and in the capture of Fort Morgan (1864) and Mobile (1865). Subsequently he was engaged on naval coast survey work (1877-1885) and became commandant of the Naval Academy (1891-1894), commander in chief of the South Atlantic Squadron (1897-1898), and superintendent of the Naval Observatory (1902-1906). He reached the rank of rear admiral in 1903, and three years later he was retired. After retirement he headed the Ottoman Development Company, which secured from the government of the Ottoman Empire the "Chester concession" to construct a railroad through Anatolia and the Mosul oil region. The successor government of the Republic of Turkey raised objections to the concession, and at the Lausanne Conference in 1923 it caused complications because of its conflict with other concessions and with British interests in Mesopotamia and French interests in Syria. Soon after the Lausanne Conference Turkey annulled the concession on the ground that certain preliminary conditions had not been complied with.

CHESTER, George Randolph, American novelist and short-story writer: b. Ohio, 1869; d. New York City, Feb. 26, 1924. After engaging in various occupations he turned to journalism, first working as a reporter on the *Detroit News*; subsequently he transferred to the *Cincinnati Inquirer*, eventually becoming Sunday editor. He gave up journalism to write magazine stories; and with Lillian de Rimo, his second wife, he collaborated in writing several novels, among them *Cordelia Blossom* (1914; play, 1914), *Runaway June* (1915), *The Enemy* (1915), and *On the Dot and Off* (1924). It was, however, his invention of the fictional character Get-Rich-Quick Wallingford, a shady company-promoter, that brought him great fame and financial success. His numerous books included *Get-Rich-Quick Wallingford* (1908); *Cash Intrigue* (1909); *The Making of Bobby Burnit* (1909); *The Art of Short Story Writing* (1910); *Young Wallingford* (1910); *The Early Bird* (1910); *Wallingford and Blackie Daw* (1913); and *Wallingford in His Prime* (1913). After World War I he entered the motion picture industry as writer and director, and continued to contribute stories to the *Saturday Evening Post* and other periodicals.

CHESTER, Joseph Lemuel, American genealogist: b. Norwich, Conn., April 30, 1821; d. London, England, May 26, 1882. He was musical editor of *Godey's Lady's Book* from 1845 to 1850, and in 1852 he became one of the editors of the *Philadelphia Inquirer*. From 1858 he made his home in London, where he made special researches into the ancestry of American families and investigated the English descent of noted Americans, especially that of George Washington. He was a founder in 1869 of the Harleian Society, which published his greatest work, *The Marriage, Baptismal, and Burial Registers of the Collegiate Church or Abbey of Saint Peter, Westminster* (1876). Other writings included *Edu-*

cational Laws of Virginia: the Personal Narrative of Mrs. Margaret Douglas (1854); *John Rogers, the Compiler of the First Authorised English Bible* (1861).

CHESTER, city, England, county seat of Cheshire, 15 miles south of Liverpool. The two main streets cross each other at right angles and were cut out of the rock by the Romans, 4 to 10 feet below the level of the houses. The houses in these streets were curiously arranged; the front parts of their second stories, as far back as 16 feet, form a continuous paved promenade or covered gallery, open in front, where there are pillars and steps up from the street below, with private houses above, inferior shops and warehouses below, and the chief shops of the town within. These arcades, called the "Rows," together with the walls and the half-timbered construction of many of the houses, with ornamental gables of the 16th century, render Chester perhaps the most picturesque city in England. St. John's Church (later [1075] St. John's Cathedral), now partially in ruins, is supposed to have been founded in 698. The cathedral church of Christ and the Virgin Mary, formerly the church of the abbey of St. Werburgh, embraces Norman to Late Perpendicular styles of architecture; it is surmounted by a central tower 127 feet high, and has a splendid Perpendicular west window. Henry VIII founded the King's School in 1541. Chester still preserves its old walls, two miles in circuit in their entirety. They date from the 14th century, replacing Norman and Roman ones, but the gates are of the 18th century. Many modern improvements have been made in the city, but with due regard to the quaint architectural features. Leather goods and paint are manufactured, as well as chemicals and boots and shoes.

Chester, which is situated on a rocky eminence on the river Dee, was known to the Romans as *DEVA*, or *DEVANA CASTRA*. The military station was founded there about 48 A.D., and subsequently it became the station of the famous 20th Legion. It was destroyed by Ethelfrith during the first decade of the 7th century, and lay in ruins until Ethelfreda rebuilt it about 907. Chester was, in 1070, the last place in England to succumb to William the Conqueror. In 1255 it suffered devastation by Llewellyn. It espoused the cause of the royalists in the English Civil War, and after a two-year stubborn siege (1644-1646) it was starved into capitulation. Pop. (1949 est.) 47,850.

CHESTER, city, Illinois, seat of Randolph County, on the Mississippi River 58 miles south-southeast of East Saint Louis; it is served by the Missouri Pacific and the Saint Louis and Southwestern railroads. It is a shipping center for iron, lead, sand, and coal; and there are manufactures of shoes, hosiery, and flour. It is the seat of the Southern Illinois Penitentiary. Fort Kaskaskia State Park is on the site of an early trading post and the first capital of Illinois. Government is by mayor and council. Pop. (1940) 5,110; (1950) 5,388.

CHESTER, city, Pennsylvania, a port of entry on the Delaware River, in Delaware County 14 miles west-southwest of Philadelphia. It is served by the Pennsylvania, the Baltimore and Ohio, and the Reading railroads and by

steamship lines. The city is the trade and shipping center of a highly developed industrial district, and has one of the largest shipyards and drydocks in the country. Chester's huge industrial interests comprise great steel mills, munitions and locomotive works, oil refineries, automobile assembly plants; manufactures of textiles, chemicals, paper products and floor coverings; and many smaller enterprises. Chester's retail trade area covers more than half of Delaware County, with a population tripling that within the city limits, and there are suburban industrial activities of major importance, greatly extending the metropolitan area. The city has excellent public parks; the Deshong Memorial Art Gallery; the J. Lewis Crozer Library; Pennsylvania Military College; and Crozer Theological Seminary (Baptist). Near by are Haverford, Swarthmore, and Villanova colleges. Of especial interest are the Caleb Pusey House (1683), the oldest building standing intact in Pennsylvania; Old Court House (1724); and Washington House (1747), where Washington wrote his report of the Battle of Brandywine, Sept. 11, 1777. Settled by the Swedes in 1644, and called Upland, Chester is the oldest town and second settlement in the state, the first settlement at Tinicum Island having disappeared. It came under Dutch control in 1655, and English in 1664, and its name was changed to Chester by William Penn when he landed here Oct. 28, 1682 on his way to Philadelphia. Chester became a borough in 1701 and was Delaware County seat from 1789 to 1851; it received a city charter in 1866. It has a mayor and council. Pop. (1940) 59,285; (1950) 65,824.

CHESTER, city, South Carolina, seat of Chester County, 18 miles south-southwest of Rock Hill; it is served by the Southern, the Carolina and Northwestern, the Lancaster and Chester, and the Seaboard Air Line railroads. There are granite works and manufactures of cotton textiles, yarn, flour, pulp wood, fertilizer, and novelty furniture. It lies in a cotton, farming, and livestock region, and also manufactures dairy products. The city was settled and named by Pennsylvanians about 1756. Pop. (1940) 6,392; (1950) 6,891.

CHESTER, city, West Virginia, in Hancock County at the northern tip of the West Virginia panhandle. Largely a residential city, there are manufactures of pottery, china, and roofing materials. The water works are owned and operated by the city government. Pop. (1940) 3,805; (1950) 3,767.

CHESTER STAGE, the youngest of the limestones laid down in the interior sea that covered in Lower Carboniferous or Mississippian time, much of what is now the Mississippi Valley. Limestones of this stage are found in Texas, Arkansas, Kentucky, Tennessee, and Alabama, and in places reach a thickness of 1,500 feet. Some of the Lower Carboniferous limestones of West Virginia correspond in age to the Chester. The characteristic fossils include several genera of crinoids and brachiopods. See also CARBONIFEROUS.

CHESTERFIELD, 4TH EARL OF (PHILIP DORMER STANHOPE), English statesman and man of letters: b. London, Sept. 22, 1694; d. there,

March 24, 1773. He was educated at Trinity Hall, Cambridge, and in 1715, after a tour in Europe, he was appointed a gentleman of the bed-chamber to the Prince of Wales. From 1716 to 1726 he sat in the House of Commons as a Whig, representing Saint Germans, Cornwall, and there displayed his considerable talents as an orator. In 1726 he succeeded his father as earl, and in the House of Lords soon exerted considerable influence. From 1728 to 1732 he was ambassador to The Hague, a post which he filled with great dexterity. His natural son, Philip (1732-1768), was born to him by a Mlle. Elizabeth du Bouchet. In 1730 he had been appointed lord high steward, but he was dismissed from this post in 1733 by Sir Robert Walpole because of his opposition to the prime minister's excise bill. Thereafter he led the opposition in the House of Lords, and in 1733 he caused deep offense to George II by his marriage to the countess of Walsingham (Melusina von der Schulenburg), illegitimate daughter of George I; he adopted his godson, a distant cousin named Philip Stanhope (1755-1815), as heir to his title and estates. He waged a bitter campaign against George II and his government, writing satirical letters under the name of Geoffrey Broadbottom. In 1744 he joined the ministry of Henry Pelham and shortly was sent as ambassador to The Hague; there he succeeded in persuading the Dutch to join in the War of the Austrian Succession. He went to Ireland in 1745 as lord lieutenant, a post which he filled with notable success, and from 1746 to 1748 he served as one of the principal secretaries of state. Retiring from public affairs in 1748, he devoted the remainder of his life almost entirely to study and the society of his friends. Because of his belated eulogy of Samuel Johnson's *English Dictionary*, in 1755 the great lexicographer rebuked him in a famous reply: "... had it been early, had been kind; but it has been delayed till I am indifferent, and cannot enjoy it; till I am solitary and cannot impart it; till I am known, and do not want it." His talents as an author were displayed in several moral, critical, and human essays, in his parliamentary speeches, and particularly in a collection of letters to his son (see CHESTERFIELD'S LETTERS TO HIS SON) which recommended grace of manners as the most essential quality for a man of the world. Another series of letters addressed to his godson showed Chesterfield in a more favorable light. To the charms of wit and grace he united good sense, a thorough knowledge of the manners, customs, and political condition of Europe, and a polished style.

CHESTERFIELD, municipal borough, England, in Derbyshire 11 miles south of Sheffield. It is situated within rich coal and iron fields, and has manufactures of steel, textiles, and pottery. The beautiful 14th century Gothic church is remarkable for its crooked wooden spire, 228 feet high and six feet out of the perpendicular. There is a grammar school founded in 1538; and Stephenson Memorial Hall was built in 1879 in memory of the English inventor, George Stephenson, whose last years were spent in the vicinity. An ancient and historic place, Chesterfield figured in several important battles of the feudal and civil wars. Pop. (1949 est.) 67,960.

CHESTERFIELD INLET, Canada, an inlet of Hudson Bay in the eastern part of the

Keewatin District, Northwest Territories. It is 250 miles long and 25 miles wide, and inland it expands into Baker Lake.

CHESTERFIELD ISLANDS, a group of 11 coral islets in the central Coral Sea, northwest of New Caledonia and 285 miles west of the Huon Islands, politically within the French overseas territory of New Caledonia. The aggregate area is about 4 square miles. There are no indigenous inhabitants. Rich guano deposits are leased to the Austral Guano Company, Limited, of Melbourne, Australia.

CHESTERFIELD'S LETTERS TO HIS SON. The letters of Philip, 4th earl of Chesterfield (q.v.) to his illegitimate son, Philip Stanhope, are to be distinguished from the letters to his godson and successor of the same name. Neither set was meant for publication. The *Letters to His Son* were written between July 1737, when the boy was five and one half years old, and 1768, when Philip Stanhope died. Composed in English, French, and Latin, they were designed to convey instruction—both by repeated precept and varied example—in language, history, literature, good manners, morality, and a general knowledge of mankind. At the age of six the boy receives Dryden's fine lines:

When I consider life, 'tis all a cheat;
Yet, fooled with hope, men favour the deceit.

For a knowledge of men, advises Chesterfield, read La Rochefoucauld and La Bruyère. Study the French character sketches, comparing them with persons you know. Better read one man than 10 books. Human nature, ever the same in essence, is varied in its operations. Discover the ruling passion deep in the heart of the individual; do not trust him where that is concerned. Avoid vulgar liaisons—cultivate polite arrangements. Choose and cultivate the best in all domains of life, but do not necessarily enter the lists as champion of anything. Let people enjoy quietly their errors both in taste and religion. Do not tell everything; acquire the art of dissimulation, and distinguish between this and simulation—never lie. The greatest fools are the greatest liars. But the father loved his son, and knew how to be a friend. His letters are full of real, not feigned, interest, and have something for every reader. Neither the son nor the godson became a pattern of wit and good breeding; but it is unfair to say that the solicitude of their mentor was lavished on them in vain. A complete edition of Chesterfield's *Letters to His Son* did not appear until 1890 (Lord Carnarvon's).

CHESTERTON, chës'tër-t'n; -tün, Gilbert Keith, English journalist and author: b. London, May 29, 1874; d. Beaconsfield, England, June 14, 1936. He attended St. Paul's School, London, where he won the Milton prize for English verse, but left in 1891 to study art at the Slade school. He began his literary career by reviewing art books for *The Bookman*. His first book, *The Wild Knight*, was published at his father's expense in 1900. While turning out volume after volume, he edited *G.K.'s Weekly*, contributed a page of causerie to the *Illustrated London News* each week, and wrote special articles for many other periodicals. Turning from verse to prose, in 1901 appeared *The Defendant*, first a series of books attacking the *fin-de-siècle*

Victorian pessimists, wherein he defended conventionality in such an unconventional manner that he soon came to be known as "the master of paradox." This was followed by *Twelve Types* (1902), and *Heretics* (1905). He was at his best in literary criticism, and his studies of Robert Browning (1903), Charles Dickens (1906), George Bernard Shaw (1909), and R. L. Stevenson (1927) were not only brilliant but of lasting value. As a poet he could be either rhetorical or humorous. His best verse is included in *Collected and New Poems* (1927). In fiction his fancy found free play and he used this medium for the expression of his pet ideas. *The Napoleon of Notting Hill* (1904) was a fantastic dream-history of civil war between London suburbs. *The Club of Queer Trades* followed in 1905; *The Man Who Was Thursday*, in 1908; *The Ball and the Cross*, and an autobiography, *Orthodoxy*, in 1909. Then he turned to detective fiction and his series of "Father Brown" stories (1911, 1914, 1926, 1927, 1935) and *The Man Who Knew too Much* (1922) won great popularity.

In 1922 Chesterton entered the Roman Catholic Church and thereafter he championed Catholicism in many of his most ambitious works. His later books included *St. Francis of Assisi* (1923); *The Everlasting Man* (1925); *The Judgment of Dr. Johnson* (play, 1927); *Generally Speaking* (1929); *The Poet and the Lunatics* (1929); *Catholic Essays* (1929); *St. Thomas Aquinas* (1933).

CHESTERTOWN, town, Maryland, seat of Kent County, on the Chester River 32 miles east-southeast of Baltimore, it is served by the Pennsylvania Railroad. It lies in a fruit-growing region, and manufactures include hosiery, lumber products, and fertilizer. Washington College is here. Pop. (1940) 2,760; (1950) 3,135.

CHESTNUT, chës'nüt, genus *Castanea*, of trees and shrubs of the beech family Fagaceae. The species are usually self sterile, requiring more than one tree for the production of nuts. The flowers consist of long catkins, which may contain the female or fruit-bearing organs at their base, or may be purely male or staminate. If the female flowers are fertilized they develop spiny burs, containing one to five nuts. There are two groups of species, the chestnuts proper and the chinquapins (chinkapins). Of the chestnuts, the American species, *C. dentata*, was formerly of great economic importance throughout its range in the eastern United States, being a tall timber tree. Its wood, which was very durable in the soil, was of particular value for telegraph and telephone poles, for construction timbers and railroad ties. But a fungus, *Endothia parasitica*, imported on Oriental chestnuts, probably in the 1890's, and causing the disease known as "chestnut blight," has now destroyed virtually all trees throughout their native range, so that now only basal shoots from the stumps of these trees remain. The nuts of the American chestnut were sweet and edible, though comparatively small. The principal Oriental chestnuts, *C. mollissima*, the Chinese, and *C. crenata*, the Japanese, are more or less resistant to the blight the former very much so, but these species cannot replace the American chestnut for timber, because of their smaller size. Hence the United States Department of Agriculture, the Brooklyn Botanic Garden, and the Connecticut Agricultural Experi-

ment Station have been interbreeding the Oriental species with the American in order to obtain a blight-resistant hybrid of timber type. Chinese-American and Japanese-American crossed with Chinese chestnut hybrids give promise of fulfilling this aim. The European chestnut, *C. sativa*, a native of southern Europe, was attacked by the blight fungus in 1938, and the disease is spreading throughout Italy, Spain, Portugal, Switzerland, and Yugoslavia. So far it has not been found in France. Since the nuts, because of their large content of starch, and also the timber, are of great value to the southern Europeans, the situation is serious. The chinquapins are usually smaller, bushlike species, with only one nut in the bur. The commonest in the United States is the Alleghany chinquapin, *C. pumila*, a native of the southeastern United States. Its nuts are small, but suitable for wild life. Because of the shrubby nature of this species, the blight is not usually fatal. Several other small chinquapins occur in the southeastern United States and also in China. The Ozark chinquapin, *C. ozarkensis*, native from southwestern Missouri to Arkansas, is a small tree but susceptible to the blight. The Henry chinquapin, *C. henryi*, a native of central and western China, is a large tree, attaining 90 feet, but also susceptible to the blight.

ARTHUR H. GRAVES.

CHETTLÉ, Henry, English dramatist: b. 1560?; d. ?1607. First heard of as editing Robert Greene's *Groatsworth of Wit* (1592), which refers to a dramatist, probably Shakespeare, as an "upstart crow," he apologized in a preface to *Kind Harts' Dreame* (?1593), an exposure of some of the abuses of his time. That he wrote for the stage we learn from Francis Mere's *Palladis Tamia* (1598), in which he calls Chettle the "best for comedy amongst us." *Englands Mourning Garment* (1603), an elegy on Queen Elizabeth, was well received. It refers to the poets under fictitious names, one verse supposed to be to Shakespeare as "silver-tongued Melicert."

CHETUMAL, chā-tōō-māl', town, Mexico, capital of the territory of Quintana Roo. It is a small town situated on the western side of Chetumal Bay near the mouth of the Rio Hondo. It is primarily a port and trading center for chicle contractors and for the wood trade, particularly that in mahogany. Pop. (1940) 4,672.

CHETWODE, chēt'wōd, Lord Philip Walhouse, 1st Baron Chetwode, English soldier: b. Rangemore, Staffordshire, England, Sept. 21, 1869; d. London, July 6, 1950. Educated at Eton College, he entered the army in 1889 and achieved regular promotion, serving in Burma, South Africa, and in World War I. After his cavalry brigade had covered the retreat from Mons, he went to Egypt in command of the Desert Corps, and later played a prominent part in the capture of Jerusalem as commander of the 20th Army Corps. He received many decorations for his gallantry.

In 1919 he was military secretary in the War Office; from 1930-1935 commander in chief of the army in India. During World War II he served as chairman of the executive committee in the British Red Cross and St. John joint war organization, and until 1948 was constable of the royal palace and the Tower of London. He was

gazetted field marshal in 1933 and created a baron in 1945.

CHEVAL, shē-vāl', A (Fr. *cheval*, horse); on horseback, astride any object. In a military sense, a body of troops is said to be à *cheval* of a river, if one wing is stationed on the right and the other on the left bank.

CHEVALIER, shēv-à-lēr', Albert, English comedian: b. London, England, March 21, 1861; d. there, July 10, 1923. Of Italian, French, and Welsh blood, he early showed a natural talent for the stage, and when 16 made his first professional appearance in London. For many years he toured with the Kendals, John Hare and George Alexander, but began his music hall career at the London Pavilion in 1891, singing the coster songs that brought him instant success. Many of these songs were still sung in World War II by the troops, such as *Knocked 'em in the Old Kent Road*, *The Future Mrs. 'Awkins*, and *My Old Dutch*. He toured the United States and Canada under the management of Charles Frohman and was a great success. His last London appearance was in a play *My Old Dutch*, founded on his popular song. Besides over 100 sketches, monologues, and plays he wrote a volume of reminiscences, *Before I Forget* (1901).

CHEVALIER, shē-vā-lyā', Maurice, French actor: b. Ménilmontant, near Paris, France, Sept. 12, 1888. His music hall career began in 1904, interrupted by service in the army in World War I, after which he became very popular singing a type of light French song and wearing a straw hat that became his trademark. He appeared in other countries, made films, chiefly *The Love Parade* (1929); *The Big Pond* (1930); *The Merry Widow*, and *Folies-Bergère* (1935). In World War II he remained in occupied France, entertaining the troops and prisoners. In 1947-1948 he again toured the United States and Canada, besides starring in the René Clair (René Chomette) film *Le Silence est d'or*. He published *Man in the Straw Hat* in 1949.

CHEVALIER, Michel, French economist: b. Limoges, France, Jan. 13, 1806; d. Montplaisir, near Lodève, France, Nov. 28, 1879. Trained as an engineer, he became a fervent follower of the radical doctrines of Claude Henri Saint-Simon, which he advocated in the Saint-Simonist journal, *Le Globe*, until sentenced in 1832 to a year in prison. Upon the intervention of Louis Adolphe Thiers, the penalty was reduced and Chevalier soon after was entrusted with several government missions. Sent to the United States to study communications, he reported on his observations in a series of brilliant letters to the *Journal des Débats*. These letters were collected under the title, *Lettres sur l'Amérique du Nord* 2 vols. (1836). In 1840 he was appointed to the Collège de France as professor of political economy. Espousing in his lectures, publications, and political activities the cause of free trade, his efforts found an echo in England and were encouraged by Richard Cobden, with whom he negotiated in 1860 a trade agreement between France and England. In the same year he was named senator by Napoleon III. Chevalier defended the latter's intervention in Mexico, a country of which he wrote *L'expédition du Mexique* (1862) and *Le Mexique ancien et moderne* (1863).

among his other writings are *Essais de politique industrielle* (1843); *Cours d'économie politique* (1842-1850); and *Comment une nation rétablit sa prospérité* (1871).

CHEVALIER, Sulpice Guillaume. See **AVARNI**.

CHEVALIER, shěv-à-lěr', an honorary title given especially in the 18th century to younger sons of the French nobility. The chevalier was originally so called because he rode a horse; but only the nobles and others connected with the upper classes could afford horses, the term chevalier came to have the sense of a chivalrous man or gallant. James Francis Edward Stuart, the Old Pretender, was called the Chevalier or Chevalier de St. George, while his son Charles Edward Stuart, the Young Pretender, was called the Young Chevalier. A Chevalier is the lowest grade in the French Legion of Honor.

CHEVAUX DE FRISE, shě-vô' dē-frěz' horses of Friesland, so called because first used at the siege of Groningen, in that province in the Netherlands, in 1658), armed beams of square timber or iron used to defend the fronts of camps, breaches, or shores by closing them up. They are usually from 15 to 18 feet long, and connected by chains, each being perforated with small holes to receive rods of wood or iron, pointed at their extremities, and when moved in any direction making a hedge of spears. In their original form they were made of spears, sword blades and other steel instruments such as were readily found at hand in the army equipment.

CHEVERUS, shě-vrūs', Jean Louis Lefebvre de, French Roman Catholic prelate: b. Mayenne, France, Jan. 28, 1768; d. Bordeaux, July 19, 1836. During the French Revolution, as a priest he refused to take the constitutional oath required of the clergy, and fled to England, later to the United States, where in 1810 he became the first Roman Catholic bishop of Boston, Mass. He ministered to the Abenaki Indians in Maine and studied their language; was honored by President John Adams; returned to France in 1823, where he was made bishop of Bordeaux, and a peer of France by King Charles X in 1826. Pope Pius VII created him a cardinal in 1836.

CHEVES, chīv'is, Langdon, American banker: b. in Abbeville district, S. C., Sept. 17, 1776; d. Columbia, S. C., June 26, 1857. He began to study law at the age of 18, and rapidly attained eminence and wealth in its practice. As a representative in the national Congress before and after the War of 1812, he zealously supported the party which carried the declaration of war. In 1812 he was chairman of the Naval Committee and in 1813 of the Ways and Means Committee; he became speaker of the House in the Thirteenth Congress when Henry Clay was sent as commissioner to Ghent. In 1815 he returned to his law practice, but in 1819 accepted the position of president of the United States Bank. The bank had become hard pressed and was on the verge of closing, but Cheves, by rigorous retrenchment, and by making credits only upon sufficient securities, saved it, and specie payments were maintained at the principal centers of commerce. He withdrew from public life because of his convictions on the dangers of separate state action.

CHEVET, shě-vě', an architectural term, meaning a variety of apse, usually confined to French Gothic churches. The extreme end of the chancel or choir is called the *chevet*. The apses of chapels are made to radiate around the choir aisle. There are generally five apses, but, especially in early architecture from the 11th century, constructions with four apses are seen. Henry III introduced the *chevet* into England, in a part of Westminster Abbey. In some French churches there are only three; but there may be seven and in still others, nine, the second one of which was generally dedicated to the Virgin Mary.

CHEVILLARD, shě-vě-yàr', Pierre Alexandre Camille, French composer: b. Paris, France, Oct. 14, 1859; d. there, May 30, 1923. Son of the famous cellist Pierre Chevillard, he studied piano under Georges Mathias, but was mainly self-taught in composition. From 1886-1897 he was assistant conductor to his father-in-law, Charles Lamoureux, whom he succeeded. He continued the *Concerts Lamoureux* and maintained the high standard established by his predecessor. In 1903 he received the Prix Chartier for chamber music, and in 1913 became president of the French Chamber Music Society. In that year he became concertmaster at the Opéra. His compositions include a symphonic ballad, a symphonic fantasy, and many piano and cello works.

CHEVIOT, shiv'ī-ūt, city, Ohio, in Hamilton County, in the extreme southwest of the state, on the western outskirts of Cincinnati. On the Chesapeake and Ohio Railroad, it is mainly a residential city, but manufactures packing boxes, clothes, and rubber goods and has a meat packing plant. Settled in 1818, it is now incorporated and has a mayor and council. Pop. (1950) 9,944.

CHEVIOT HILLS, chěv'ī-ūt, a range on the borders of England and Scotland, stretching southwest to northeast for above 35 miles, the larger part of the range being in Northumberland, England, and the lesser part in Roxburghshire, Scotland. Their culminating point, known especially as the Cheviot, has a height of 2,676 feet; Carter Fell, the next in height, is a little more than 2,000 feet high. The hills are clothed for the most part with a close green sward, and are pastured by a celebrated breed of sheep admirably adapted for hilly districts. In these hills are formed the head waters of the Tyne, the Tweed, and other rivers of the border country.

CHEVIOT SHEEP, a breed of sheep of large size and valuable fleece, which has been pastured for centuries in the Cheviot Hills, on the border of England and Scotland, and which from its powers of endurance is justly regarded as one of the most valuable mountain sheep of Great Britain. The peculiar features of the Cheviots are the usual absence of horns in both sexes; white or grayish face and legs; a long head, destitute of wool, while both throat and neck are well covered; long open ears well covered with hair, and every indication of hardness. Well-fed ewes weigh approximately 125 pounds and wethers (castrated rams) may reach 200 pounds. The fleece weighs from three to four pounds in ewes and up to 12 pounds in rams. The Cheviots, though originally confined to a small area, are now widespread in all parts of the British Isles. Most sheep raised in northern

Scotland are of this variety. Cheviot wool is widely used for wearing apparel.

CHEVREUL, shě-vrûl', **Michel Eugène**, French chemist: b. Angers, France, Aug. 31, 1786; d. Paris, April 9, 1889. Educated in his native town, when still a youth he went to Paris, and was employed in the chemical factory of Louis Vauquelin. In 1813 he became chemistry professor in the Lycée Charlemagne, and in 1824 was made director of dyeing in the Gobelins tapestry works, and in 1830 took the chair of chemistry in the Museum of Natural History. He wrote *Leçons de chimie appliqué à la teinture* (1828-1831) and *De la loi du contraste simultané des couleurs*, translated into English as *Principles of Harmony and Contrast of Colors* (1839). His real fame, however, rests on his *Recherches chimiques sur les corps gras d'origine animale*, for his researches on animal fats led to improvements in soap and candle making; and to his discovery of oleine and stearine, which he named.

CHEVREUSE, shě-vrûz' **DUCHESSÉ DE (MARIE DE ROHAN-MONTBAZON)**, French political intriguer: b. Dec., 1600; d. Gagny, near Paris, Aug. 12, 1679. She intrigued all her life in love and politics. Twice married, first at 17 to the duc de Luynes, who died soon after, and then to Claude de Lorraine, duc de Chevreuse, she made many other conquests. As a friend of the queen, Anne of Austria, she was an inmate of the royal household, and had opportunities for opposing the duc de Richelieu and later Jules Cardinal Mazarin. Some of her exploits have been celebrated as fiction by Alexandre Dumas. Escaping from Richelieu, she swam the Somme in man's attire and fled to England. Finally Anne allowed her to return, in spite of Louis XIII's objections, and gave her a pension, but did not allow her as much confidence. After plotting against Mazarin, she became one of his spies.

CHEVROLET, shěv-rô-lâ', **Louis**, American automobile racer, designer, and manufacturer: b. La Chaux-de-Fonds, Switzerland, 1879; d. Detroit, Mich., June 6, 1941. Educated in France, where his family moved when he was a boy, he went to the United States in 1900 to represent a French concern in Brooklyn, N. Y. He became the world's leading automobile racing driver, defeating Barney Oldfield in 1905 for the first time at Sheepshead Bay, N. Y.

In 1911 he designed and built, with William C. Durant, the first Chevrolet automobile, but in 1914 sold out to Durant, who incorporated the firm in General Motors in 1915. Continuing as a racing driver, Chevrolet won the Indianapolis Speedway races in 1920 and 1921 with cars built to his own design. In 1925 he took up speedboat racing, adding to his triumphs, and later organized the Chevrolet Aircraft Company in Indianapolis. From 1936-1938 he returned to the Chevrolet company in a minor office.

CHEVRON, chěv'rûn (Fr. *chèvre*, a goat), in heraldry, a bent bar or shield, rafter shaped. A chevron is, according to some authorities, a third, and according to others, a fifth of the field. A chevronel is half a chevron, and the couple close the fourth of the shield. A chevron couped is that which does not reach the sides of the escutcheon. A chevron in chief is one which rises to the top of the shield.

In architecture a chevron is a zigzag molding, characteristic of Romanesque architecture in France, England, and Sicily. It is a common decoration of the Norman arch.

Its most familiar use is as a badge of rank by officers of armies, navies, police, and other uniformed bodies. See **INSIGNIA OF RANK, MILITARY AND NAVAL**.

CHEVROTAIN, shěv'rô-tân (Fr. *chevrot*), a family, Tragulidae, of ruminant ungulates, resembling true deer, particularly the musk deer in some respects, but considerably more primitive and sometimes called mouse deer. Besides the presence of canine tusks, the complete absence of antlers, face and foot glands, the stomach has only three chambers instead of four, the lateral metacarpals or hand bones are complete, as in the fibula or calf bone. Chevrotains are small animals, about a foot in height, and occur almost entirely in thickets and dense forests. Two genera are recognized, *Tragulus* of southeastern Asia, and *Hyemoschus* of West Africa. Three species of *Tragulus* are known, one, *T. meminna*, differing from the others in being spotted. It is confined to Ceylon and southern India. The other two species are of a plain reddish or grayish color, and occur farther east, both ranging from Indochina to Malaya, Borneo, and Sumatra. The smaller species, the Kanchil, *T. javanicus*, unlike the larger, *T. napu*, also occurs on Java. The single African species, the water chevrotain, *H. aquaticus*, is somewhat larger and more heavily built than the Asiatic forms. Chevrotains are considered to be relatively unchanged survivors of the Eocene ancestors of true deer.

CHEVY CHASE, chěv'ī chās', the name of a celebrated border ballad probably founded on some actual encounter occurring between Sir Henry Percy and the Earl of Douglas, although the incidents mentioned in it are not historical. It is this ballad that Sir Philip Sidney speaks of when he says, in his *Defense of Poetry*, "I never heard the old song of Percie and Douglas that I found not my heart moved more than with a trumpet."

There are two versions of the ballad bearing the name of Chevy Chase, an older one and a more modern one. The older version is sometimes called the *Hunting of the Cheviot*, which is its original title. It begins thus:

The Persè owt of Northombarlande,
And a vowe to God mayd he,
That he wolde hunt in the mountayns
Off Chyviat within dayes thre,
In the mauger of doughte Dogles,
And all that ever with him be.

Neither the exact age nor the name of the author of this version is known. From the fact that it is mentioned in the *Complaynt of Scotland*, written in 1548, where it is called the *Huntis of the Chevot*, it is clear that it was known in Scotland before that time, and since James of Scotland is mentioned in the ballad, it may be inferred that it was not written before the reign of Henry VI, for James I did not ascend the throne of Scotland until two years after Henry VI had become king of England.

The age of the more modern version is not better known than that of the older one, but it is said to be no later than the reign of Charles I. This is the version which forms the subject of a critique by Joseph Addison in Nos. 70 and 74 of

the *Spectator*. The following is the opening stanza as given in Percy's *Reliques*:

God prosper long our noble king,
Our lives and safetyes all;
A woefull hunting once there did
In Chevy-Chace befall.

CHEVY CHASE VILLAGE, Maryland, in Montgomery County, northwest of and adjoining the District of Columbia. Established as a suburb of Washington, D.C., in 1890, it was incorporated in 1914 and governed by a board of seven elected managers, employing a superintendent of public service. In 1947 a further area was added; in 1951 an act was passed changing the name, originally Chevy Chase, by adding Village. Strictly residential, and served by a main highway, it maintains the peace and privacy of its beautiful homes. Pop. (1953) 2,300.

CHEW, Benjamin, American jurist: b. West River, Md., Nov. 29, 1722; d. Jan. 20, 1810. He studied law in Philadelphia in the office of Andrew Hamilton and later in London. He returned to Philadelphia in 1743 and held successively the offices of register of wills, attorney general and chief justice of Pennsylvania. He joined the ranks of the Loyalists on the outbreak of the Revolutionary War. The war terminated his provincial offices and he retired to private life. General Washington continued to be friendly with Chew despite the fact that he would not sign a parole. During the battle of Germantown his mansion there was badly damaged in the bombardment. From 1791 to 1808 Chew was president of the high court of errors and appeals, which was abolished in the latter year.

CHEWING GUM, a resinous gum used as a masticatory. The habit of chewing gum is perhaps peculiar to the United States. At first the resinous exudations of the spruce, cherry, etc., were employed in their native state; but with the increase of the habit the spruce supply nearly failed, and recourse was had to other ingredients. The gum resins of sweet gum, tamarack and certain other forest trees are also used. Balsam of tolu is a constituent of certain kinds of gum, while paraffin has also been employed. Paraffin is also very largely used as an adulterant in the cheaper grades of gum, which in consequence crumble when chewed. Of late years a gum known as chicle, an elastic gum from the maseberry, a tree of tropical South America, somewhat similar to the India-rubber tree (q.v.), has come into favor as the foundation of most of the chewing gum. The chicle gum is chopped into fine particles, dried and then cooked in steam-jacketed kettles. At this stage, sweetening and flavoring ingredients are added to the mass, which is mixed mechanically. The resulting "dough" is then kneaded on a table and rolled between rollers having knives set into their faces. These knives cut the sheets into suitable sizes for the market, and, after drying, the sticks are wrapped, packed and shipped. The practice of chewing gum is probably harmless, and in mild cases of indigestion it may even be somewhat beneficial, by mechanically stimulating the flow of saliva. Pepsin, mint and similar substances are often mixed in with the gum; thymol being added in the so-called antiseptic gums, but it is safe to say that the commercial success of any particular brand depends more upon its sweetness and flavor than upon any beneficial properties.

The production of chewing gum in the United States has increased at a rapid rate, and by 1949 the output of the factories devoted exclusively to its manufacture had attained an annual production worth more than \$141,250,000.

CHEWINK. See TOWHEE BUNTING.

CHEYENNE, shí-én' (Sioux, *Shahiyena*, i.e. people of alien speech or foreigners; in their own language, the name means "our people"), a tribe of the North American Algonquin linguistic family, and its westernmost member except for the Blackfeet. Their earliest known habitat was the area that became Minnesota, although the tribe took part in several great migrations, as well as the period in which they followed a nomadic life, pursuing the bison. The Cheyenne were one of the 11 major tribal groups in the western plains area. Unlike some other tribes, which formed close confederations in other places, such as the Pawnee and Iroquois League groups, the Cheyenne, like other marginal tribes, had little more than informal alliances. The tribe migrated westward along the Cheyenne River, stopping for several generations in the Black Hills, then moving on to the Platte River uplands. It was about 1830 that they formed two bands, a northern group and a southern.

The Cheyenne had a typical plains culture and history. According to the tribal tradition, they had lived originally in a very cold climate, where they were an agricultural people, cultivating corn and other crops. They also knew how to fashion pottery; but these arts were lost when the tribe became roaming buffalo hunters and nomads, roving the plains between the Arkansas and Missouri rivers.

Generally speaking, the Cheyenne had been friendly toward United States settlers, concluding certain treaties with them, but in 1861 the southern branch began hostilities because of the numerous violations by United States forces and settlers of agreements made with the Indians. In 1864 the Sandy Creek, Colorado, massacre took place, where the United States Army slaughtered Indian warriors, women and children alike. This action infuriated the Cheyenne who instigated one of the most bitter of the Indian wars. In 1868 Custer's victory on the Washita River, destroying the Indian camp, ended the hostilities. The history of the northern Cheyenne has been more peaceable.

The Cheyenne are a tall people, perhaps the tallest of the Great Plains groups. They are a well-built race. Their language is one of the most difficult of the Indian tongues, although the Cheyenne speech is closer to the central Algonquin dialect than are those of some of the other tribes. The Cheyenne still maintain, in the reservation, their complex social organization. They live in tepee, observe the rite of the Sun Dance and other tribal ceremonies.

The first treaty between the tribe and the United States was in 1825. The locale was the mouth of the Teton River, South Dakota; tribal recognition and provisions for trade were established, but no reservation was designated. After the tribal schism into northern and southern branches, the new southern section formed a confederacy with their Algonquin kinsmen, the Arapaho, along the Arkansas River. Unfortunate incidents with the United States Army and settlers ensued and there were many treaty violations, but

in 1892, the present reservations in Montana and in Oklahoma were accepted.

The Cheyenne and Arapaho languages were so different, that the two tribes became very proficient in the sign language in their intercourse with each other. These two tribes are perhaps most proficient in this language.

Consult Grinnell, George B., *The Cheyenne Indians*, 2 vols. (New Haven, Conn. 1923); Peter, R. C., *Reminiscences of Past Years in Mission Service Among the Cheyenne*, 1st ed., paper bound (Lame Deer, Mont. 1936); Llewellyn, Karl N., and Hoebel, E. A., *Cheyenne Way* (Norman, Okla. 1941).

C. ROSS HUME,
Attorney at law, Anadarko, Okla.

CHEYENNE, shi-én', city, Wyoming, is the capital of the state and seat of Laramie County. It is in the southeastern part of Wyoming on a plateau 6,060 feet above sea level, and is 106 miles north of Denver. Just west of the city is Medicine Bow National Forest. Cheyenne is served by the Union Pacific, the Colorado and Southern, and the Burlington railroads. The city has good airline connections from its municipal airport which is equipped with large airplane repair shops. Cheyenne lies at the intersection of three transcontinental highways, and a three-mile boulevard extends northwest from the city to the Francis E. Warren Air Force Base. Near this base are the Pole Mountain Maneuver Grounds of the United States Army. Coal, iron, oil, and other mineral deposits are worked in the vicinity of Cheyenne, and dry farming and cattle and sheep grazing are large and important industries. Cheyenne ships beef cattle (especially Herefords) and sheep to eastern markets, and is an important wholesale trade center. Among its newer industries are oil refining and airplane tool manufacture. There are good winter sports in the Pole Mountains and Snowy Range west of the city, and Cheyenne is the supply depot for much of the game hunting and sport trade of the Rocky Mountains.

The city is administered by three commissioners (elected every two years) under the commission form of government. There is a municipal system of waterworks which cost 5½ million dollars. Cheyenne is attractively laid out with broad streets and boulevards, and its public parks and ornamental lakes cover 800 acres. Annually, during the last full week in July, Frontier Park is the scene of the Frontier Days celebration which provides the largest wild West show of its kind in the world and includes a pageant of transportation and a rodeo. Since 1897, when it was instituted, it has attracted thousands of visitors. The city's buildings of special interest are the state capitol, the State Office Building, the federal building and post office, the governor's mansion, the city hall and county courthouse, the state supreme court building (with a fine reference library), a veterans' hospital, a Carnegie library, the Industrial Club, the Union Pacific Station, the Convent of the Holy Child Jesus, and St. Mary's Catholic Cathedral.

History.—Cheyenne was named after a tribe of Algonquin Indians of the west. It was founded in 1867 when the Union Pacific Railroad reached this point in its westward building, and was incorporated in 1869. A fort was built to protect the railroad workmen and settlers. The Union Pacific established its main repair shops there, which, with yards for the division, now occupy a 470-acre tract. In 1868, Cheyenne was made

the seat of Laramie County and the following year it was selected as the capital of Wyoming Territory, maintaining that position when Wyoming became a state (Cheyenne still holds its position as temporary capital. A referendum submitted to the voters, as required by the state constitution to determine a permanent capital, has failed to give any Wyoming city a majority of the votes cast). Cheyenne boomed as an out-fitting point for miners and as the center of a great cattle empire. From its beginnings, its strategic location in transcontinental transportation was the major factor in its growth. Between 1870 and 1900, population increased from 1,450 to 14,087; and in 1950, reached 31,935.

CHEYNE, chān, **George**, Scottish physician: b. Methlick, Aberdeenshire, 1671; d. Bath, England, April 13, 1743. He started a London practice about 1702, and shortly after was elected a fellow of the Royal Society. His health began to fail, perhaps as a result of his free living. He derived so much benefit from strict adherence to a milk and vegetable diet that he recommended it in all his later medical treatises, which included *New Theory of Fevers* (1702); *Philosophical Principles of Religion* (part 1, 1705); *Essay of Health and Long Life* (1724); and the *English Malady* (1733).

CHEYNE, Thomas Kelly, English Biblical scholar: b. London, Sept. 18, 1841; d. Oxford, Feb. 16, 1915. He was educated at Merchant Taylors' School, Worcester College, Oxford, and spent some time at Göttingen where he heard Georg Heinrich Ewald lecture. In 1868 he was elected fellow of Balliol College and from 1885 to 1908 he was Oriel professor of the interpretation of Scripture at Oxford. In 1884 he became a member of the Old Testament revision board. His numerous works deal exclusively with the exposition and criticism of the Old Testament books, the most important of which was his joint editorship, with J. Sutherland Black, of the *Encyclopaedia Biblica*, 4 vols. (1899–1903).

CHEYNE, Sir William Watson, English surgeon: b. off shore, near Hobart Town, Tasmania, Dec. 14, 1852; d. Fetlar, Scotland, April 19, 1932. He was educated at Edinburgh University and was Hunterian professor of the Royal College of Surgeons of England, 1888–1890, and its president, 1914–1917. He was created baronet in 1908. He published *Antiseptic Surgery* (1882); *Manual of the Antiseptic Treatment of Wounds* (1885); *Manual of Surgical Treatment*, 7 vols.

CHEYNE-STOKES RESPIRATION, an irregular breathing common in severe cases of diseases of the heart, kidneys, or cerebral affections. The respirations occur in a cycle, increasing rapidly then decreasing, finally reaching a point of total cessation for from 5 to 50 seconds. After a pause, the cycle begins all over again. Such a state usually presages death.

CHEYNEY, chā'nē, **Edward Potts**, American educator and sociological writer: b. Wallingford, Pennsylvania, Jan. 17, 1861; d. Feb. 1, 1947. After graduating from the University of Pennsylvania in 1883, he took a postgraduate course there, and later traveled abroad, studying in German universities and at the British Museum. Upon

his return he was appointed professor of European history in the University of Pennsylvania. He has written *Social Changes in England in the 16th Century* (1896); *Social and Industrial History of England* (1901); *A Short History of England* (1904); *Background of American History* (1905); *Readings in English History* (1908); *A History of England, from the Defeat of the Armada to the Death of Elizabeth* (1914).

CHEZY, shā-zē, Antoine Leonard de, French Orientalist: b. Neuilly, France, Jan. 15, 1773; d. there, Aug. 31, 1832. He began his studies in the École Polytechnique, and, unassisted, taught himself Sanskrit, and became so proficient in it that, in 1815, a chair of Sanskrit was formed expressly for him in the College of France. Among his productions is a free French translation of the Persian poem, *Medjoun et Leila*. He also published Kalidasa's drama of *Sakuntala*, in the original, with a translation accompanied with notes.

CHHATTISGARH, chūt' ēs-gār, Indian Union, the southeast division of the Central Provinces, comprising formerly the districts of Raipur, Bilaspur and Sambalpur, and several small feudatory states. In 1906 Sambalpur was given to Bengal, and the district of Drug constituted out of parts of Raipur and Bilaspur. Its area is 37,688 square miles. It is mainly a vast fertile plateau, and has of late become a great center of the Indian grain trade. Dongargāon is the capital. Pop. (1941) 4,050,000.

CHIABRERA, kyā-brā'rā, Gabriello, Italian lyric poet: b. Savona, June 8, 1552; d. Savona, Oct. 14, 1637. Impatient of dependence on the great, he again and again abandoned the courts of noble patrons. He visited Rome and resided a considerable time at Florence and Genoa, settling finally in his native place. Wherever he went he was loaded with presents and honors. Pindar and Anacreon were his models among the poets, and his countrymen named him "the Italian Pindar," but his Pindaric odes have little grace and force, being labored rather than spontaneous. Some of his little songs after Anacreon are models of elegance and grace. He wrote epic and dramatic poems also. He showed himself a master of complex rhythms, ambitious and new in form, and a master of the Italian language such as had never before appeared. He was the last of the great Italian writers until the appearance of Manzoni in modern times. He left a charming autobiographical sketch. His collected poems were published under the title of *Rime*.

CHIANA, kyā'nā, (the ancient CLANIS) a river of central Italy, originally a tributary of the Tiber, watering a perfectly level valley, which its overflow rendered once the most pestilential district of Italy. The bed was deepened in 1789-1816, and in 1823 extensive hydraulic works were undertaken for further improving the river course, and for leading a north branch, through canals, to the river Arno, a few miles below Arezzo, the south stream reaching the Tiber through the Paglia at Orvieto. The double stream is 60 miles long, and one-half to one mile broad, and the district has since become one of the most fruitful in all Italy.

CHIANG KAI-SHEK, jē-āng' kī'shēk', Chinese statesman and general: b. Chikow, District of Fenghwa, Chekiang Province, China, Oct. 31, 1887. He received his military training at the Chinese military academy at Paoting, and the Tokyo Military College, being graduated from the latter after a four-year course. While in Tokyo he became an adherent of Dr. Sun Yat-sen, and upon his return to China he joined the Kuomintang, or People's Party. He participated in the Revolution of 1911 and the establishment of the Chinese Republic, and was thereafter closely associated with Doctor Sun, taking part in minor civil wars and the quelling of various insurrections until 1916, when he engaged temporarily in business. He returned to his service with Sun in 1920, and later was sent to Soviet Russia to study military methods, after which he was appointed head of the Whampoa Military Academy. He became commander in chief of the army in 1925, after the death of Doctor Sun, and in 1926 first came into international prominence through his successful expedition against the war lords of Northern China. He broke relations with the Communists in China and rid himself of the Russian Soviet advisers of the Sun era in 1927, establishing the capital at Nanking; resigned in August of that year, but was recalled again to lead the army early in 1928, and afterward marched northward and occupied Peiping. He was president of China's Nationalist government in 1928-1931, as well as commander in chief of its army, but again withdrew from office, in the hope of eliminating dissension among party groups, and was succeeded in the presidency by Dr. Lin Sen. Reappointed to command the army in 1932, he continued to make civil war against the Communist groups. In 1936, however, disaffection in the northern armies and the forces under the "Young Marshal," Chang Hsueh-liang, led to the kidnapping of Chiang, who was held for two weeks at Sian in undoubted peril of his life. Thanks to skillful mediation, a settlement was reached whereby it was agreed that the Communist issue should await settlement as a political problem, while the country faced the Japanese menace united under Chiang's leadership.

Upon the outbreak of war with Japan in 1937 he assumed full command of Chinese military activity; and from China's declaration of war against Germany and Italy, Dec. 8, 1941, he was continuously a member of United Nations military councils until the end of the war.

In 1943 he was again made chairman of the Executive Yüan of the Nationalist Government (provisional president), and represented China at the Cairo Conference. On the successful conclusion of the war with Japan, Chiang returned to Nanking with the object of rebuilding the country and crushing the Communists. On May 20, 1948, he was sworn in as China's first constitutional president. However, unable to stem the tide of Communist victories, he retired from office on Jan. 21, 1949, turned over the reins of government to Vice President Li Tsung-jen, and left Nanking. In May he flew to Formosa and began organizing the island as a last defense bastion for the Nationalist cause. Continuing Communist victories motivated his announcement on March 1, 1950 that he was resuming the presidency.

His second wife, MEI-LING, or MAYLING, Soong, to whom Chiang was married in 1927, was

born in Shanghai in 1898, and was graduated from Wellesley College in 1917. Shortly after their marriage Chiang became a Christian (Methodist) convert. Mme. Chiang, inspired by democratic and Christian ideals, worked for the welfare of the Chinese people, and during the war years she played a leading role in national defense and international diplomacy, spending much time in the United States in an endeavor to secure greater aid for China. She joined her husband in Formosa in 1950. Her published works include *China in Peace and War* (1940); *This Is Our China* (1940); and *China Shall Rise Again* (1941).

CHIAPANECs, chē-ā-pā-nēks', or **CHAPANECs**, a tribe of Indians of central Chiapas, Mexico. They are supposed to have entered Mexico much earlier than the Aztecs, from whom they borrowed part of their religion and culture. They were also influenced by the Mayas of Yucatan and northern Guatemala. Although they were able to escape Aztec domination, they were easily conquered by the Spaniards. Remains of the old Chiapanec civilization have been excavated at El Sumidero, San Pedro Buenavista, and other sites.

CHIAPAS, chyā'pās, state, Mexico, situated on the Pacific coast, between the Isthmus of Tehuantepec and Guatemala, with an area of 28,729 square miles. The capital is Tuxtla. Inland from the coastal plain rises the Sierra Madre del Sur. The state is well watered by the Usumacinta and Grijalva rivers and their tributaries. In the north, at Palenque, are celebrated Maya ruins. The fertile valleys produce henequen, coffee, tobacco, corn, sugar, cotton, and fruit, and the forests yield ebony, cedar, and mahogany. Cattle, sheep, and hogs are raised. A branch of the National Railways of Mexico runs parallel to the coast, and the Sureste Railway crosses the northern part of the state. Pop. (1950) 907,026.

CHIAROSCURO, kī-ā-rō-skū'rō (Ital. *chiaro*, light + *oscuro*, dark), a term used in painting with reference to the distribution of lights and darks, and extended to art criticism in general as the harmonious blending and composition of light and shade effects. Although the problem of chiaroscuro appears in varying degrees in all periods of the history of art, it is the subject of particular attention in Leonardo da Vinci's *Treatise on Painting*, in which he observes that the intensification of light and shadow strengthens the relief effect (modeling) of the forms, but also adds beauty through the interpenetration of light into the shaded areas and shadows into the lighted sections of the painting. These effects appeared in his own paintings, and became even more prominent in the work of Il Giorgione and the colorists of the north Italian schools. A penetrating realism combined with a strong, almost theatrical use of light and dark became the distinctive feature of Michelangelo da Caravaggio and his followers in Italy, Spain, France, and the Netherlands during the 17th century. The most outstanding master of chiaroscuro is Rembrandt, whose use of light as a means of modeling forms and creating the illusion of a free-flowing space around them was combined with a sensitivity that made light an expressive medium in its own right. Though most dramatic in his painting, as in *The Night*

Watch, the effect is consistently carried through his drawings and graphic work, which have become the principle sources for the inspiration of 19th and 20th century specialists in chiaroscuro.

CHIAVARI, kyā'vā-rē, commune, Italy, situated in Genova Province, Liguria, on the Gulf of Rapallo, 22 miles east-southeast of Genoa. A resort and market town, it has food-processing plants, tanneries, and establishments producing silk, lace, linen, furniture, and ships. There are attractive public gardens, a museum, and a cathedral built in 1613. Pop. (1951) 20,324.

CHIAVENNA, kyā-vā'nā, commune, Italy, situated in Sondrio Province, Lombardy, on the Mera River, at the north end of Lake Como, 25 miles west-northwest of Sondrio. A tourist center at the junction of the Splügen and Maloja passes leading through the Alps to Switzerland, it produces skis, shoes, woolen cloth, stoves, and beverages. Pop. (1951) 6,039.

CHIBA, chē'bā (Jap. chē-bā), city, Japan, capital of Chiba Prefecture, Honshu, situated on Tokyo Bay, 20 miles east of Tokyo. It has a medical school and an 8th century Buddhist temple. Paper, cotton goods, and processed food are produced. Pop. (1950) 133,844.

CHIBCHAS, chīb'chās, or **MUYSKAS**, mwēs'kās, the native population of the high plateau of Bogotá in central Colombia at the time the region was discovered by Europeans. The Chibchas were a farming people, cultivating corn, potatoes, quinoa, and a long list of other native Andean food crops. They lived in towns, some of them of considerable size; Chibcha Bogotá, for example, is reported to have contained 20,000 houses. The buildings in these towns were constructed of wood, with walls of cane and mud, so that they have not produced the spectacular ruins found in areas like Mexico and Peru. The Chibchas wove cotton cloth for clothing and made jewelry of gold and emeralds.

Politically, the Chibchas were organized in many small city-states, often at war with one another. In the early 16th century A.D., the Zipa dynasty of Bogotá under Nemequene and his nephew, Tisquesusa, built up a powerful feudal state in the southern third of Chibcha territory. The rival Zaque dynasty at Tunja provided the major opposition, but there were a number of lesser rulers involved as well. The Zipa maintained considerable state and enjoyed absolute power in his dominions.

Chibcha religion was rich in mythology, in ceremonies, and in organization. A number of the chief gods were nature deities, of whom the Sun was one of the most important; human sacrifices were made to him. Other deities received offerings of gold, emeralds, incense, corn, beer, and other prized materials. Fasting and ritual bathing were practiced, and public ceremonies included imposing processions. There was a professional celibate priesthood, and the Chibchas recognized a high priest of the entire nation named Sugamuxi.

The Chibchas were conquered by Spanish armies between 1536 and 1541, and their religion and native political organization were soon suppressed. The Chibcha language became extinct in the 18th century, but the descendants of the Chibchas, numbering over a million, still form the

basic rural population of their original homeland.

Consult Kroeber, A. L., "The Chibcha," *Handbook of South American Indians*, Bureau of American Ethnology Bulletin 143, vol. 2, pp. 887-909 (Washington 1946); Pérez de Barradas, José, *Los Muiscas antes de la conquista*, 2 vols. (Madrid 1950-51).

JOHN HOWLAND ROWE,
University of California, Berkeley.

CHIBOUQUE, *chí-bōōk'*, **CHIBOUK**, **CHIBUK**, a long Turkish pipe having generally a wooden stem, an amber mouthpiece and a clay bowl. The stem, which is usually from four to five feet long, is generally wound with silk, cotton or other thread. This is frequently kept wet to cool the smoke of the pipe by evaporation.

CHICA, *chē'kā*, **PITO**, *pē'tō*, or **POSO**, a kind of beer made from maize, in general use in Chile, Peru and other mountainous regions of South America. It was the national drink of the natives long before the appearance of the Spaniards. The most ordinary method of preparing it is to steep the grains of maize until they begin to sprout, when they are exposed to the sun. The malt thus prepared is then ground, mixed with warm water and left to ferment. The beer, when ready, has a dark-yellow color and a pleasant and somewhat bitter and sour taste. It is consumed by the Indians in great quantities. When Chica has been buried for some time in the earth in pitchers it has a violently intoxicating effect.

Chica is also an orange-red coloring matter prepared by the Orinoco Indians from the leaves of a plant called *Bignonia chica*.

CHICACOLE, *chik-a-kōl'*, or **CICACOLE**, India, a town in the Ganjam district, Madras Presidency, near the coast, about 567 miles northeast of Madras, at one time famous for its fine muslin manufactures. On two occasions, namely in 1791 and 1866, it suffered much from famine, and in 1876 a flood did considerable damage to the town. Pop. (1941) 22,250.

CHICAGO, county seat of Cook County, Illinois; a port of entry; largest city in the state, and second largest in the country; located on the west shore of Lake Michigan near its southern tip. The city is the greatest rail center in the world; is a major industrial, commercial, and financial center, and dominates a metropolitan area that extends into northern Illinois and Indiana, southeastern Wisconsin, and southwestern Michigan. Rail, motorbus, air, and boat lines connect the city with every part of the United States and give access to all American seaports.

Geography.—The city stands on a low, remarkably flat lake plain whose loose, gravelly, and sandy soils lie deep over the bedrock. The evenness of the region has made drainage difficult, while the heavy overlay of surface materials has challenged engineering skill in building construction. The Chicago River, formerly emptying into Lake Michigan but now an outlet for the lake, flows westward about one mile from the lake shore and then separates into its north and south branches. This river system creates the principal divisions of the city: the South Side, lying between Lake Michigan and the main river and its south branch; the North Side between the lake and the main river and its north branch; the West Side, between the river branches and

the western city limits. In the extreme southern portion of the city is Lake Calumet, a shallow body of water, connected northeastward to Lake Michigan by the canalized Calumet River, and westward to the Mississippi Valley watershed by the Little Calumet River and the Calumet Sag Channel. The Loop, narrowly defined, is that section bounded by Lake, Wells, and Van Buren streets and Wabash Avenue, above which the elevated trains into the city loop (hence the name) before beginning their return trips to the outlying sections. In common parlance, the Loop refers to the somewhat larger, but less definitely marked off, main business section. It may be considered to comprise the area bounded by the river on the north and west, Van Buren Street on the south, and Michigan Avenue on the east. The incorporated area of Chicago is 212.8 square miles. The official elevation at the lake is 579.88 feet above sea level, the gentle westward rise of the land from the water's edge giving the city an average elevation of about 600 feet. Average temperatures are 25.7°F. for January and 73.9°F. for July; the average annual precipitation is 31.85 inches.

Population.—Chicago did not appear in the federal census until 1840, at which time it had a population of 4,470 and ranked 54th among the country's cities. In 1860, the Chicago population reached six-digit proportions, its 109,260 inhabitants bringing the city into 8th place among urban centers. With the 1880 count, Chicago passed the half-million mark; and, in 1890, the million. In subsequent enumerations the population has been: 1,698,575 (1900); 2,185,283 (1910); 2,701,705 (1920); 3,376,438 (1930); 3,396,808 (1940); 3,620,962 (1950). Since 1890, Chicago has been outranked among American cities only by New York. The city has grown by influx from other regions of the United States and from abroad, and by annexation of neighboring communities.

Chicago's population is an amalgam of virtually every ethnic and racial strain. While this population of diverse origins results in tensions and stresses that constitute a major problem, the city is indebted to its various component groups not only for the contribution of sheer manpower which each makes, but for contributions of color, variety, and cultural enrichment. Next to the phenomenal growth of numbers, perhaps the most significant change through the years in Chicago's population has been the increasing numerical preponderance of the native-born, white element. In 1870, this group made up only half of the total population; by 1940, it had risen to nearly three fourths. Another significant development has been the sharp increase in the number of Negro citizens. The intense economic activity which accompanied each of the world wars opened opportunities to which the Negro responded by large-scale immigration to the city. By 1940, Chicago had 324,102 Negro inhabitants (30,150 in 1900), most of whom lived on the South Side in an area roughly rectangular in shape, with South Parkway as its major axis.

Transportation.—No city in the world surpasses Chicago as a railroad center. Chicago is served by 19 major trunklines. The large downtown terminals are supplemented by numerous neighborhood and suburban stations in the handling of passenger traffic; and extensive switching yards, belt lines, and freight subways care for the vast volume of goods that enter and leave the

city each day. Though there had been agitation for the consolidation into one location of all passenger terminals, these facilities still remained dispersed in 1950, the principal ones being the Dearborn, Central, Grand Central, Union, La Salle Street, and North Western stations.

Chicago is a major aviation center. Passenger arrivals and departures averaged nearly 200,000 per month at the end of 1949. Passenger, express, and freight service is supplied by over 30 airlines. The most important airfields are those operated by the aviation bureau of the city: Municipal Airport on the South Side; Meigs Field on the lake front, and O'Hare Field on the city's northwest perimeter. Municipal Airport (1928, first full year of operation) is equipped with all modern facilities and safety devices. An observation deck on the terminal building, open to the public, provides a vantage point from which the field's activities may be surveyed. In 1950, O'Hare Field (called Douglas until June 22, 1949) was in an early stage of the \$3,100,000 development provided for by the Illinois legislature. Numerous auxiliary fields are located in the Chicago area.

The provision of adequate internal transportation facilities for the city's millions can fairly be termed Chicago's greatest problem. The basic street pattern is a severely rectangular grid of north-south and east-west streets cut across by a few diagonal avenues, and supplemented by a belt of outer drives running north-south along the lake front. Approximately 70,000,000 persons a month ride the elevated trains, street cars, trackless trolleys, and street buses operated by the municipally owned Chicago Transit Authority. Taxis and privately owned buses augment the CTA's carriers. Obvious inadequacies of internal transport led to the creation, in November 1938, of a department of subways and superhighways. Under the direction of this department, the city embarked on an ambitious program designed to alleviate traffic congestion. One part of the program involved depressing a portion of the elevated trackage beneath the ground surface into a series of subways. The other part called for construction of a network of superhighways radiating from the central business district and interconnected by a crosstown route. Operation of the first section of the subway system (cost \$34,120,000) was inaugurated Oct. 17, 1943. Tiled walls, fluorescent lighting, escalators, and conveniently arranged exits and entrances made the underground stations both striking in appearance and highly functional. The west route of the superhighway system was farthest advanced in 1950. In the business district, sidewalks were to be passed by arcades through the buildings flanking Congress Street, over which the highway passes, to permit extension of the roadway to a width of 68 feet.

Thousands of workers and shoppers pour into the city each morning on the commuter trains of various railroads and return at late afternoon to their suburban homes. The Illinois Central is Chicago's largest commuter carrier, and second largest in the United States; its suburban lines were electrified in 1926.

Industry and Commerce.—The Chicago industrial area is one of the marvels of American economic life. Favored by central location, an abundance of level land, inexhaustible water supply, ready access to great coal fields and iron deposits, and strategic relationship to the Great

Lakes and Mississippi Valley waterways, the city has maximized these natural advantages by application of a vigorous business and civic leadership and the skills of an able labor force. The primacy of industry in Chicago's economy is shown by the fact that in 1949 more of the gainfully employed were to be found in manufacturing (43 per cent) than in the next three fields combined (trade, 21 per cent; service establishments 12 per cent; transportation, communication, public utilities, 9 per cent). This industrial area leads all others in the production of worked metal products, commercial printing, meat and packinghouse products, telephone equipment, cosmetics and soap, radio and television apparatus, confectionery, electrical equipment, and many other kinds of goods. Over 12,000 establishments produced 11 billion dollars worth of manufactured goods in 1949.

Meat packing has long been the city's leading and most distinctively characteristic industry. The West Side stockyards cover hundreds of acres, and receive a constant flow of live animals for sale or reshipment. The packinghouses are noted for converting "everything but the squeal" into usable products.

Chicago is famed also as the great grain-trading center of the United States. It has elevator warehouses in which vast quantities of wheat are held and a world market for cereal grains in the Board of Trade Building at Jackson Boulevard and La Salle Street. As Wall Street in New York regulates trade in securities, so La Salle Street in Chicago directs trading in grain. The "pits," as the trading posts of the board of trade are called, are scenes of feverish activity as brokers negotiate the purchase and sale of millions of bushels of grain for immediate or future delivery.

The Chicago area became a major center of American steel production with the expansion, after 1900, of the industry on the shorelands in southern Cook County and adjacent Lake County, Indiana. As in the case of the livestock and grain industries, so too for steel has strategic location been a decisive factor. Transportation facilities for handling the basic raw materials—ore, fuel, and limestone—plus a steady and diversified labor supply have resulted in a producing center of tremendous capacity. Steel-fabricating plants quite naturally have associated themselves with this source of supply. Worked steel comes from these factories in every conceivable form, from railroad rails and structural shapes to bolts, nuts, rivets, and washers.

Wholesale trade is nearly as important to the city as its industrial output. Buyers are attracted by such permanent institutions as the Merchandise Mart and the Furniture Mart, and by numerous trade shows and fairs held every year. The retail trade derived from Chicago's own inhabitants and visitors to the city is augmented by the mail-order business for which Chicago is noted. Aaron Montgomery Ward pioneered in this field with his North Clark Street establishment in 1872; and Richard Warren Sears, after earlier business ventures, founded Sears, Roebuck & Company in 1893. Retail selling by mail partly accounts for the fact that more domestic money orders and more parcel post packages are handled by Chicago post offices than by those of any other city.

The existence of Chicago as a lake port, to speak rather fancifully, antedated its existence as a town, for the Indian used the city's present

site as a landing place for his canoe long before the white man came. From Chicago's earliest days, access to the outside world by way of Lake Michigan's waters has been an important asset. Existence as a Mississippi Valley port is of much more recent origin. The Illinois-Michigan Canal, completed in 1848, connected the Chicago River with the Illinois, a tributary of the Mississippi. This canal was superseded by the Sanitary and Ship Canal (1900) joining the Chicago River and the Des Plaines, a branch of the Illinois. Further improvement of the Des Plaines and Illinois rivers made possible the opening in 1933 of the Illinois Waterway, giving Chicago a through water route to the Mississippi, and thence to the Gulf of Mexico. The city's principal docks are at Calumet harbor, in the Calumet River, along the south branch of the Chicago River, and at Navy Pier which juts into the lake just north of the river's mouth. Navy Pier and Calumet harbor are protected by extensive breakwaters. In 1949, water-borne traffic handled by harbors in the Chicago area amounted to nearly 49,000,000 tons; a little over one-half was reported at the Port of Chicago, and most of the remainder at the steel ports of Gary and Indiana Harbor.

Two private corporations, the Commonwealth Edison Company and the Peoples Gas Light and Coke Company, supply electricity and gas, respectively. The Illinois Bell Telephone Company had nearly a million and a half phones in active service in 1950.

Buildings.—Chicago can be justly proud of much that has been built; of some, it is duly ashamed. A city of steel and concrete, brick and tile, replaced the wooden city that stood before the Great Fire of 1871. In the Loop and on the Near North Side cluster towering skyscrapers, monuments to engineering skill and financial acumen. Office buildings, huge department stores, and capacious hotels characterize the downtown section. Outlying neighborhoods have grown into cities within the city proper. But, in 1950, mingled with imposing business edifices and the attractive homes and apartment hotels of the well-to-do were the city's slum areas. While progress was being made, the slum-clearance program had much before it in the form of challenge.

Noteworthy among public buildings are the City Hall-County Building and the United States Court House (1905) in the Loop. The former, though named as one building, is actually two. The county's half was built in 1907; the city's, in 1910. State Street is marked as the heart of the retail merchandising section by such department stores as Marshall Field & Company; Carson, Pirie, Scott & Company; and The Fair. Randolph Street is Chicago's "Broadway," and La Salle Street is its "Wall Street." To the later thoroughfare the massive buildings of financial institutions impart a decidedly substantial, if somewhat somber, air. Throughout the Loop and in its immediate environs are found such noted hotels as the Stevens (still the world's largest in 1950), the Palmer House, the Sherman, the Morrison, and the Blackstone.

Chicago is the home of the skyscraper. When William Le Baron Jenney built the Home Insurance Building (1884-1885) and William Holabird the Tacoma Building (1887-1888), no other city in the world had seen the steel-skeletoned structure that is now so familiar. By 1930, the city boasted 32 buildings over 300 feet tall. Since World War I, skyscraper construction has been

concentrated on the Near North Side and along Wacker Drive. Notable for beauty are the Wrigley Building, bathed at night by floodlights; the Tribune Tower, with its flying buttresses; and the Palmolive Building, atop which shines the Lindbergh Beacon. All these are on North Michigan Avenue. Facing the north shore of the river near its fork is the Merchandise Mart (1930), a 24-story structure of reinforced concrete faced with Indiana limestone. Here manufacturers and wholesalers display goods to buyers, and literally thousands of "lines" are shown. Wacker Drive is a double-decked boulevard built during the administration of Mayor William E. Dever (1923-27). Roughly L-shaped, the drive extends for seven blocks along the southern shore of the main river, then turns at the forks and continues southward for an additional four blocks. At its southern tip stands the Civic Opera Building, completed at a cost of \$20,000,000 in 1929. The gala opening of the Civic Opera, Jan. 29, 1929, was a milestone in Chicago's history, as it marked the abandonment of the old Auditorium where forty years before Adelina Patti's Juliet had thrilled those gathered for the opening of that hall. The Auditorium (acquired by Roosevelt College in 1947) was designed by Louis Henri Sullivan and Dankmar Adler, and its acoustical perfection made it the marvel of its day. Among other buildings worthy of note are: Orchestra Hall (1904), financed partly by residents of the city as a memorial to the great conductor, Theodore Thomas, who was director of music at the World's Columbian Exposition (1893) and conductor of the Chicago Symphony Orchestra, 1891-1905; the American Furniture Mart, on Lake Shore Drive, a wholesale marketing center; the Daily News Building (1929), the first in Chicago whose construction involved the purchase of air rights.

Education.—Chicago is, as befits its size and central location, one of America's great educational centers. The public school system, with hundreds of buildings, hundreds of thousands of students, and millions of dollars invested, is administered by a board of education whose members are appointed by the mayor. Following the standard American system, its organization includes elementary and high schools, junior colleges, special schools for handicapped children, night schools, vocational schools, and a teachers college. Instruction is designed to coordinate routine studies and exercises with development of mental initiative and practical training. The parochial school system is organized on a scale commensurate with the size of the city, and comprises elementary schools, high schools, and academies.

In the field of higher education, Chicago is outstanding. The University of Chicago (1890) is a world-renowned center of research and instruction. Northwestern University (1851), located in the north shore suburb of Evanston, maintains many of its professional schools at the Chicago campus on the Near North Side. The Illinois Institute of Technology was established in 1940 by the merger of two older schools, Armour Institute of Technology (1892) and Lewis Institute (1896). Roosevelt College, founded in 1945, occupies the former Auditorium Hotel on Michigan Avenue. The University of Illinois maintains in the city an undergraduate branch on Navy Pier, as well as its colleges of dentistry, medicine, and pharmacy. Among Catholic institutions are DePaul University (1898), Loyola

University (1870), Mundelein College (1930), and Rosary College (1922) in suburban River Forest. Rush Medical College (now the Rush Graduate School of Medicine of the University of Chicago) was a pioneer in its field when it was incorporated in 1837. Other institutions abound which offer training in the mechanical arts and allied subjects, nursing, physical and occupational therapy, business and commerce, and almost countless other fields.

Cultural Institutions.—The Chicago Natural History Museum, formerly the Field Museum (1893), is housed in a majestic building of white Georgia marble at the south end of Grant Park. The museum is one of the world's great scientific institutions, engaged in both the collection and diffusion of knowledge. Its comprehensive exhibits are arranged in four major classifications: anthropology, botany, geology, and zoology. The scope and variety of the museum's work are such that it serves layman and specialist alike. Its program includes the support of research expeditions, publication of scientific treatises, lectures, and radio programs, in addition to the maintenance of its public exhibits. Its facilities are extensively used by faculty and students of the city's colleges and universities. The exhibits of the Museum of Science and Industry, in Jackson Park, illustrate the contributions of applied science to human life. The fact that its exhibits work—that, indeed, they may be manipulated by the visitor himself—increases their effectiveness and fascination. Especially popular are the operating coal mine, iron foundry, and oil refinery, and exhibits illustrating such modern wonders as radar and atomic fission. The Chicago Academy of Sciences (1857) in Lincoln Park has a splendid collection of Americana, particularly along lines relating to Chicago and the Middle West. Its exhibition halls are open to the public without fee, and the academy publishes scientific papers from time to time. The Adler Planetarium building (1930) at the south end of Grant Park houses the planetarium instrument and an astronomical museum. Nearby is the John G. Shedd Aquarium (1924) with approximately 350 species of fresh- and salt-water fishes and other aquatic animals from every quarter of the earth.

The Chicago Historical Society (1856) has expanded its exhibits from a small case of "antiques and relics" in 1858 to an irreplaceable, and hence literally priceless, collection that fills the galleries of its home in Lincoln Park. Its library and museum are treasure houses of national and local historical lore. Lincoln Hall contains many personal possessions of the martyred president. A collection of more than 4,500 costumes portrays American dress from the 18th to the 20th century. The Art Institute of Chicago (1882), on the Michigan Avenue side of Grant Park, is an outgrowth of the older Chicago Academy of Fine Arts (1879). The institute has permanent collections of the highest quality, and exhibitions of loan collections are frequently held. Such artists as Lorado Taft, Frank Duvenek, and George Bellows have taught in the institute's school of fine arts. Courses in industrial and dramatic arts are also given. The foregoing seven institutions are located in parks governed by the park district commissioners, but all except the Adler Planetarium have their own boards of trustees.

Chicago is amply endowed with libraries. The Chicago Public Library (1872) had its beginning

after the fire of 1871 in a collection of over 8,000 books sent by sympathetic English friends of the city. Chiefly responsible for this benefaction was Thomas Hughes, author of *Tom Brown at Rugby*, and among the donors was Queen Victoria. After occupying in succession four locations (the most unique being an abandoned steel water tank), the central library opened its doors on Oct. 9, 1897 at the present location between Washington and Randolph streets on Michigan Avenue. Auxiliary to the central library are numerous branches and subbranches throughout the city. Two privately endowed libraries are famed throughout the world of scholarship. The John Crerar Library (1897), opposite the public library on Randolph Street, is devoted to the natural and social sciences. Newberry Library (1887) on the North Side emphasizes the humanities. The city maintains a Municipal Reference Library where public records may be consulted. The Midwest Library Center serves as a pool in which member institutions may deposit their little-used volumes, thus relieving the strain on their own facilities. The Library of International Relations (1932) on the Near North Side specializes in foreign newspapers, magazines, and official documents. The libraries of the two universities and of the smaller colleges contribute to Chicago's cultural resources, as do those of the various museums and other institutions.

Recreation.—A wide variety of spectator sports may be enjoyed at every season of the year. Comiskey Park (1910) on the South Side is the home of the American League White Sox, and Wrigley Field (1914) on the North Side is used by the National League Cubs. These parks are the scenes of professional football, wrestling, boxing, and other contests in addition to their major league baseball games. Soldier Field at the south end of Grant Park is a gigantic stadium used for festivals and public gatherings as well as for athletic contests. The Chicago Stadium (1929), west of the river on Madison Street, is an indoor arena where hockey, basketball, tennis, and other types of sporting events are held. Numerous other halls, stadia, and fields hold similar contests. The colleges and high schools of the city have their enthusiastic followers, and their athletic squads contest before large crowds. The city parks, private clubs, school grounds, and college campuses have facilities where large numbers of people enjoy participation sports. The city is famed for its park system, dating from the establishment by the city council in 1839 of Dearborn Park on the present site of the central public library. In 1934 an important step toward efficiency and economy was taken by the creation of the Chicago Park District consolidating the 22 park districts then existing. The five commissioners of the park district, appointed by the mayor, have control over the principal parks; other parks and recreational areas remain within the jurisdiction of the department of public works and the board of education.

Along the lake front lie three great parks, Lincoln, Grant, and Jackson, connected by the belt of outer drives. Lincoln (1,119 acres) lies on the North Side; among its facilities and attractions are a golf course, bathing beaches, play fields, bridle paths, a conservatory, and the zoo. Statues and memorials honor, among others, Sieur de la Salle, Hans Christian Andersen, Eugene Field, Benjamin Franklin, Friedrich von Schiller, Johann Wolfgang von Goethe, Giuseppe Gar-

baldi, and John Peter Altgeld, governor of Illinois (1892-1896). Its Lincoln statue, like another in Grant Park, is by Augustus Saint-Gaudens. Grant Park (303 acres) is the city's "front yard." It is situated on the lake front from Randolph Street to 14th Street. Its principal features are a band shell and Buckingham Memorial Fountain. The fountain stands in a beautifully landscaped plaza; into its 280-foot pool falls the spray from its jets and central geyser. During summer months colored lights play on the fountain at night. Summer evenings bring concerts at the band shell, at which distinguished conductors and soloists appear with a symphony orchestra. Jackson Park (543 acres) on the South Side stands on the site of the Columbian Exposition of 1893. Besides its play fields, beaches, bridle paths, and similar attractions, the park has a lagoon where rowboating is enjoyed, and a bird sanctuary. Much of the land on which these three parks are built, as well as the area traversed by the outer drives, is "made" land reclaimed from the lake by dredging and filling.

About one mile west of Jackson Park is Washington Park at the west end of the Midway Plaisance, which cuts through the campus of the University of Chicago. The university's noble Gothic buildings add beauty to the Plaisance, the scene of college intramural games during the spring and autumn and the location of ice-skating rinks in the wintertime. Washington Park (371 acres) has a boating lagoon, a field house, and other facilities. In all, the city has 243 other parks and recreational areas, many of them equipped with field houses, natatoriums, and other permanent fixtures.

The Cook County Forest Preserves give Chicagoans means of enjoying the pleasures of wild and semiwild country on a scale unavailable to the residents of any other American metropolis. While this belt of over 37,500 acres on the city's outskirts contains facilities for such sports as golf, swimming, and tobogganing, its unique value lies in the opportunity it affords the urban dweller of escaping from the congestion, turmoil, and tension of the city to beautiful and relaxing natural surroundings. Amateur photographers, hikers, bird-watchers, naturalists, and picnickers find in these forest lands boundless resources for the promotion of their avocations. Here, also, is the home of the Chicago Zoological Park (popularly called the Brookfield Zoo) where animals are kept as nearly as possible in re-creations of their natural habitats.

Churches, Charities, and Institutions.—

With its more than 2,000 churches of all denominations, Chicago has few that antedate the Great Fire of 1871. Among many churches noted for their architecture or beauty of ornamentation are the Chicago Temple (Methodist-Episcopal) in the Loop, Holy Name Cathedral, the Fourth Presbyterian Church, Temple Shalom, Rockefeller Memorial Chapel, and the diminutive but gem-like Thorndike Hilton Memorial Chapel of the Chicago Theological Seminary. Hull House (1889), Northwestern University Settlement (1891), the University of Chicago Settlement (1894), and the Chicago Commons Social Settlement (1894) are outstanding in work among the underprivileged. Municipally maintained institutions include the laboratories, clinics, and other services of the board of health; the Municipal Tuberculosis Hospital and the Convalescent

Home. State, county, and federal government, as well as several universities and other agencies, support and conduct the activities of the Medical Center on the West Side. The center is an expanding aggregation of hospitals, clinics, laboratories, schools, and other facilities. The department of welfare, besides providing institutional care for thousands of applicants, carries on an extensive rehabilitation program and dispenses relief and assistance in a number of forms.

Government.—The problem of governing Chicago's millions is complicated by the fact that no governmental unit corresponds to the metropolitan area which socioeconomic conditions have created. The boundaries of Chicago and Cook County are not coterminous; the sanitary district includes a large area outside the city's limits; and in addition to these three major units, there are a number of lesser ones, some of them with their own taxing and bonding powers being virtually autonomous.

The executive head of the city is the mayor, elected for a term of four years. He presides over the unicameral council, the legislative body composed of one alderman from each of the city's wards (further subdivided into precincts). The mayor has extensive appointive power, naming the members of the board of education, the park district, the public library board, the municipal sanitarium board, and a number of special commissions. Finances are administered by the department of finance headed by the comptroller. Revenues of the general corporate purposes fund are derived about equally from the tax levy and from miscellaneous sources, of which the most important are licenses, franchise compensations, and the amusement tax. Besides the corporate purposes fund, there are auxiliary funds (for example, water funds, bond funds, retirement funds) into which revenues are received and from which disbursements are made. Disbursements from the corporate purposes fund were nearly \$77,000,000 in 1948; and from all funds, over \$280,000,000.

The police and fire departments and the bureaux of streets and electricity account for nearly two thirds of all expenditures from the corporate purposes fund. The police department is headed by a commissioner, under whom serve 40 district captains, the heads of the detective and traffic bureaux, and officials of other divisions. The department's activities lead to the prosecution of hundreds of thousands of cases and the recovery of millions of dollars worth of lost and stolen property each year. The fire department, also headed by a commissioner, maintains land- and water-borne fire-fighting apparatus, ambulances, and other emergency equipment. The bureau of streets has charge of the public ways—streets, sidewalks, and alleys. Besides paving, cleaning, and maintaining the city's 3,800 miles of streets, the bureau supervises sidewalk paving (done under private contract), collects refuse, removes snow, destroys weeds, and cares for traffic markers and street signs. The bureau of electricity has charge of street lighting, safety island and curb lighting, the traffic signal system, and the police and fire alarm systems. The police and fire signal network alone, with its 26,000 miles of wires and cables, is the equivalent of the communications system of a fair-sized community.

There is a multiplicity of other departments and bureaux, each responsible for a sector of the public service. Most employees are under civil service, administered by a civil service commis-

sion. The municipal courts are headed by an elected chief justice and associate judges. Also having jurisdiction in the city are the county courts, state superior and circuit courts, and federal district and appellate courts. However, a large majority of all cases arising in the city are handled by the municipal court system, which has numerous special branches such as a court of domestic relations, a boys' court, and a women's court.

A city is analogous to a biological organism in that it will perish by starvation of its supply of water is cut off, or by self-contamination if its waste products are not removed. Hence for the city the problems of water supply and of waste disposal are intimately connected. Chicago, unlike many other cities, has no problem so far as a water source is concerned, for Lake Michigan is an inexhaustible reservoir at the city's front door. But the problems associated with the transport of water and with the prevention of contamination have taxed engineering skill to the utmost. Chicago's water is drawn from the lake through inlets (cribs) located two to three miles offshore. It is gravity-fed through tunnels to pumping stations, and then forced into the mains. Chlorination at the pumping stations is the principal means of purification. This basic system was modified, and greatly improved, for the South Side with the placing in operation (May 1947) of the south district filtration plant. Water used in the south district (about one third of the city's total) is completely treated by settling, coagulation, filtration, and the use of activated carbon. Chicago's water system (under the direction of the bureau of public works) bears an ever-increasing burden. In addition to meeting the demands of its own growing populace, the city supplies more and more outlying districts whose plants have become overburdened or whose sources of ground water are failing. In 1947, about 7 per cent of the average daily pumpage of 980,000,000 gallons went to these suburban areas. Contamination is the great danger to Chicago's supply, for Lake Michigan's waters are safe in their natural state. The outflow of wastes from the city, originally dumped into the lake, so imperiled this supply that drastic steps had to be taken. In 1889, the sanitary district of Chicago was established. The district comprises 407 square miles and serves about four million people. Under its direction the Sanitary and Ship Canal, connecting the Chicago River to the Des Plaines (thus reversing the flow of the former), and the Sag Channel, connecting the canal and Lake Calumet, were built to provide a gigantic sewer flushed by the waters of Lake Michigan. This process of "dilution" became inadequate as the city grew, and was replaced by a system of treatment which effectively removes waste from the collected sewage water. Waste water is initially collected by local sewers operated by the city, and then dumped into the interceptor sewers of the sanitary district. From the interceptors the water is drained into settling tanks where solid wastes are removed. The remaining wastes, which have not yielded to the settling process, are removed by activated sludge. The waste water, then virtually free of objectionable materials, is finally discharged into the canal. The treatment works have a capacity of over a billion gallons per day. The sanitary district is governed by an elected board of trustees.

History.—Like Rome, Chicago "was not built

in a day," but the extraordinary rapidity of its early growth was a source of wonderment. Though the town was not incorporated until 1833, by the end of the 19th century a foreign observer declared Chicago to be "the greatest expression of American genius." The French explorers, Jacques Marquette and Louis Joliet (qq.v.), are known to have visited the site of Chicago in 1673. During the era of exploration, the easy portage at this point made it much frequented by adventurers, missionaries, and agents of the French government. Thus the white man came to know the locality which long before had been recognized by the Indian as a natural crossroad. The French claim was transferred by the Treaty of Paris (1763) to British hands, but neither France nor Britain developed in any extensive way the commercial and military potentialities of the region. After the American Revolution, both Virginia and Connecticut laid claim to the section; but all claims were finally renounced in favor of the federal government (1784–1786). As a part of the Northwest Territory created by the Ordinance of 1787, the Chicago region was organized as Knox County in 1790. Successive county reorganizations followed, ultimately terminating in the formation of Cook County, as a subdivision of the state of Illinois, in 1831. Two years later, Chicago was incorporated as a town; and, in 1837, as a city (population 4,000).

Early life in the settlement was that of the typical frontier trading center and military outpost. In 1803–1804, a stockaded fort, Fort Dearborn, was built on the south bank of the Chicago River where Michigan Avenue now passes, as a link in the defense of the northwest frontier and a stabilizing influence among the Indians. The garrison at Fort Dearborn was not large, and with mounting unfriendliness among the Indians during the War of 1812 the decision was reached to abandon the post. On the morning of their departure (Aug. 15, 1812), the evacuees were attacked from an ambush near the fort; and 51 of the company, including several women and children, were slain. Of the survivors, all of whom were taken captive, a number later perished at the Indians' hands. A second Fort Dearborn was built in 1816–1817. Trade with the Indians during the first two decades of the 19th century was principally carried on by a government factor attached to the fort, but demands of private traders forced the closing of the government's trading operations in 1822. The days of the Indian in Chicago soon drew to a close, however; in September 1833, provisions were made for removal of all Indians from the vicinity, and three years later (1836), Fort Dearborn was abandoned.

In the early period the development of water transportation was a factor of prime importance in the town's development. The opening of the Erie Canal in 1825 provided a highway for immigration to the West; and the removal of the sand bars, which so blocked the mouth of the Chicago River as to make it unusable as a harbor, began in 1834. As new settlers took up their homes in the town and trade and commerce flourished, Chicago experienced a flurry of the land speculation mania so common to frontier areas. During the early 1830's, land values skyrocketed, and Chicagoans found themselves in the floodtide of a prosperity as specious as it was exhilarating. Unsupported by much in the way of material achievement, the boom was short-lived.

and the whole economic structure collapsed in the general panic of 1837. The town now lapsed into a decade of stagnation, and many of her citizenry despaired of the future. Ultimate recovery and further progress had to wait on more substantial accomplishments.

Construction of the Illinois and Michigan Canal, linking Lake Michigan and the Mississippi River system, commenced in 1836, was completed 12 years later (1848). That same year, the opening of the first railroad line into the city, the Galena and Chicago Union, marked a new era in which land transportation would set the pace. While river, canal, and lake continued to be of immense value as carriers, more and more it was the expanding rail network that wrought the transformation of Chicago from frontier post to modern city. Chicago's development as the commercial outlet for a rich hinterland brought recovery from the disastrous panic which paralyzed the city in the years following 1837. By mid-century, wheat, meat, and lumber had laid a solid foundation for Chicago's economic growth.

Though hit hard by the panic of 1857, Chicago renewed her advance in Civil War years when the city supplied large amounts of war matériel; and business expansion continued after peace returned. The Union Stockyards opened in December 1865, providing facilities for the livestock industry far superior to those which had hitherto been afforded by the smaller, scattered yards. The packing industry, too, underwent a process of rapid consolidation that resulted in the disappearance of many small firms and the appearance of such great establishments as Armour and Company, and Libby, McNeill and Libby. Long-distance shipment of refrigerated meat began in the late 1860's, and the processing of meat byproducts was developed into an important adjunct of the packing industry. While Chicago had turned to the manufacture of iron products in the 1850's, it was not until after the Civil War that pig iron was made in the city. By the 1870's the foundations were laid for the gigantic iron and steel industry that was to come. Rail connections with the Mississippi River had been established in 1854; the completion of the Union Pacific Railroad in 1869 gave the city access to the Pacific coast. By 1870, through travel from Chicago to New York was a possibility; and in 1873, the last link was forged in a trunkline from the city to New Orleans and the Gulf of Mexico. The founding of the Pullman Palace Car Company in 1867 gave the city one of its distinctive industries closely associated with the railroad boom. Merchandising flourished, as did manufacturing and transportation. Great retailing firms of the city grew to take their places among the nation's leaders. As supplements to the already firmly-established trade with the Middle West, trade with the South was rapidly resumed after the Civil War ended, and soon salesmen and agents spread the city's wares to the developing Southwest.

The disaster of 1871, the Great Fire, actually opened the way for new advancement by destroying a large part of the city. The wooden buildings swept away by the flames were replaced by more substantial structures of brick and stone. The fire broke out Oct. 8, 1871, in a barn on De Koven Street. The barn belonged to Patrick O'Leary, and familiar legend has it that Mrs. O'Leary's cow kicked over a lantern, igniting the straw strewn about. There had been a

drought, so everything was dry. The flames quickly got out of the firefighters' control, and the fire swept toward the northeastern section of the city. On Oct. 9, the North Side burned; with destruction of the waterworks, the struggle to save the city became hopeless. Homes, hotels, stores, factories, business buildings, schools, churches, railroad stations, bridges, all were wiped out. Property loss was estimated as follows: buildings and improvements, \$50,000,000; produce, lumber, and provisions, \$5,000,000; dry goods and manufactures, \$75,000,000; household property, libraries, etc., \$57,000,000—a total of \$187,000,000. Loss to the city in public buildings and property was placed at \$2,500,000.

Recovery from this disaster was unbelievably rapid. Alternating periods of prosperity and depression marked the economic life of Chicago in the late 19th century, as they did that of the country at large. But despite bitter depressions in 1873-1879, 1883-1886, and 1893-1897, the city forged ahead. A spirited rivalry between Chicago and St. Louis for leadership among the cities of the Mississippi Valley was finally resolved in favor of the former during the 1870's. The census of 1870 revealed the two cities as neck and neck in the race; but by 1880, Chicago (with 503,185 inhabitants), had left St. Louis (with 350,518) far behind. The decades after the Civil War saw an economy based on trade and the agricultural and extractive industries change to an economy in which manufacturing and finance played an ever-increasing part. Just as the town had grown to city in earlier days, so the city expanded to metropolis. Chicago owes her metropolitan status in no small degree to the far-sighted, boldly aggressive, and sometimes ruthless business leaders whose careers were inextricably interwoven with the city's history. Cyrus H. McCormick (agricultural implements), William B. Ogden (railroads), Potter Palmer (real estate, merchandising, hotel business), Philip D. Armour and Gustavus F. Swift (meat packing), Marshall Field (merchandising)—to mention these names (and a score and more of others) is to evoke a picture of the dynamic energy that characterizes the city. It was Chicago's good fortune that in an age of the most intense individualism there were many men of this kind who, for all their personal ambition, retained a civic consciousness and contributed to the common good through their wisdom and their generous benefactions.

By 1880, Chicago had a labor force of over 450,000 workers. Faced with the problem of making their way in a changing economy, and restive under the hardships that were their lot, workmen sought to better their condition by organization. The city became one of the focal points of the developing labor movement. Such periodic outbreaks of labor violence as the rioting connected with the great railroad strikes of 1877, the Haymarket Square Riot (q.v.) of 1886, and the Pullman-rail strike of 1894 have been highly publicized because of their dramatic qualities. More fundamental, but less spectacular, contributions of the city's leaders and workers have sometimes been overlooked. The Illinois State Federation of Labor (1884) and the Chicago Federation of Labor (1895) became models of state and city organization, copied throughout the country. Their influence did much to secure liberal and equitable legislation by which workmen have benefited. A number of present day

international unions are outgrowths of early Chicago local organizations. Chicago has become a strongly unionized city. Development of great labor organizations, like the rise of great business enterprises, was one of the evidences of Chicago's maturation.

As has been true in most other states, jealousies and misunderstandings between the rural areas and the expanding city reflected a disparity in modes of life and habits of thought. Often the result was inhibiting legislation that kept Chicago's political institutions from evolving to meet new problems. Nevertheless, progress was made, even though long delayed. Creation of the sanitary district in 1889, and piecemeal passage of amending legislation that liberalized the Chicago charter of 1875 were steps in the right direction. In 1906, a municipal court system was established, and in 1907 the mayoral term was lengthened from two to four years. In 1921, the city's wards were reorganized and increased in number from 35 to 50; at the same time, representation in the common council was changed so that each ward had one instead of two aldermen, resulting in a more compact and manageable legislative body. In 1934, aldermanic terms were extended from two years to four. In the same year, creation of the consolidated park district abolished one of the city's worst jurisdictional tangles, which had developed during the years by the erection of numerous autonomous park districts. Frequent annexations of adjacent territory have extended the city limits. The largest single annexation was that voted on June 29, 1889. It added 125 square miles of territory, and more than quadrupled the city's area.

Chicago's development has been guided in later years by the Chicago Plan Commission, instituted in 1909 as a permanent advisory body whose members are appointed by the mayor. Daniel H. Burnham, Chicago architect and chief of construction for the Columbian Exposition of 1893, aroused the community to a realization of the city's shortcomings and inspired it to enthusiasm for projects of improvement. Burnham's comprehensive plan recognized the various phases of the problem, utilitarian, aesthetic, and cultural: improved facilities of transportation, expanded recreational facilities, and improvement of the park system and the lake front. Some of Burnham's specific suggestions have been carried out, some modified, and some rejected; but the whole schedule of civic advancement in Chicago since 1909 has been influenced by his study of the needs and the possibilities.

The 1920's was a period of turbulence in Chicago's history, the period of the bootlegger, the racketeer, and the gangster. While marred by violence, corruption, and abuse of public trust, the decade saw solid accomplishments, too. In these years Buckingham Fountain, the Planetarium, and the Museum of Science and Industry were built, adding new beauty to the lake front, along which additional drives were constructed. The tempo of economic life quickened, products of the city's factories mounting to over 3 billion dollars by 1929. Then came the depression period of the 1930's, during the emergence from which Chicago, the United States, and all the rest of the world became involved in World War II. As in previous wars, Chicagoans contributed loyally to the nation's efforts. Men, money, and material were forthcoming in vast amounts. It was also in wartime Chicago that man pro-

duced the first atomic chain reaction, an achievement that led to the climactic termination of the conflict and may well have set the stage for a revolutionary transfiguration of the world that the future alone can reveal.

DAVID M. BEHEN,
Sometime Lecturer and Assistant in History,
The University of Chicago.

CHICAGO, BURLINGTON & QUINCY RAILROAD, popularly known as the Burlington Route, a system operating extensively in the upper Mississippi and Missouri River valleys and between the Great Lakes and the Rocky Mountains. The original corporate unit of the system was the Aurora Branch Railroad Company, chartered in Illinois Feb. 12, 1849; changed to Chicago and Aurora Railroad Company June 22, 1852, and to the present corporate title of Chicago, Burlington & Quincy Railroad Company on Feb. 14, 1855. The first track built was from Aurora to West Chicago. Burlington rails reached the Mississippi River opposite Burlington, Iowa, in 1855; the Missouri River near Omaha, in 1869; Denver, in 1882; St. Paul, in 1886; and Billings, Mont., in 1894. In connection with the Hannibal & St. Joseph Railroad, which it subsequently acquired, the Burlington established the first rail service between Chicago and the Missouri River in 1859.

The length of road operated on Dec. 31, 1949 was 8,873 miles, of which 8,297 were owned and 576 were leased or operated. The mileage owned, by states, was as follows: Nebr., 2,675; Ill., 1,615; Iowa, 1,016; Mo., 1,157; Wyo., 678; Colo., 392; Kans., 217; So. Dak., 168; Wis., 220; Mont., 135; Minn., 23. Including second, third, and fourth tracks, and yards and sidings, the total mileage owned was 12,549.

The principal routes of the Burlington are between Chicago and Denver via Omaha; Chicago and St. Paul-Minneapolis via the Mississippi River; Chicago and Kansas City and St. Joseph via Quincy; St. Louis and Minneapolis; St. Louis and Denver via Kansas City and St. Joseph; Kansas City and Omaha; Lincoln and Billings; Chicago and St. Louis and Paducah; and Denver and Billings. Over 97 per cent of the capital stock of the Burlington is owned in equal parts by the Great Northern and the Northern Pacific railways, with which it connects at St. Paul and Billings to form a through route to the Pacific Northwest. The Burlington, in turn, controls the Colorado and Southern Railway which provides a rail route from Wyoming to the Gulf of Mexico.

Early in 1950, equipment consisted of 967 locomotives, 43,819 freight cars, and 1,073 passenger cars including 13 streamlined diesel Zephyr trains. A Burlington Zephyr, completed April 9, 1934, was America's first diesel-powered, streamlined train. On May 26, 1934, it set a world's record

by traveling non-stop from Denver to Chicago in 13 hours 5 minutes—1,015 miles at an average speed of 77.6 miles an hour. America's first Vista Dome car, a stainless steel coach embodying an elevated, glass-enclosed dome, was put in service between Chicago and the Twin Cities, St. Paul and Minneapolis, on July 23, 1945. In 1950, 23 Vista Dome cars were in operation on the scenic routes between Chicago and the Twin Cities, and Chicago and San Francisco.

On Dec. 31, 1949, the capital stock of the company totaled \$170,839,100; its funded debt, \$182,337,061; and its total assets \$688,688,966. The road and equipment were valued at \$757,887,340; accrued depreciation and amortization, \$173,025,359; net, \$564,861,981. Operating revenue during the year ended Dec. 31, 1949, totaled \$217,996,508; operating expenses, \$167,265,649; net railway operating revenue \$50,730,859, and net railway operating income, \$19,620,338.

H. C. MURPHY, *President*.

CHICAGO, INDIANAPOLIS AND LOUISVILLE RAILWAY (familiarily known as the MONON) traces its corporate ancestry back to the New Albany & Salem Railroad Company which was chartered by the State of Indiana on July 31, 1847. At that time, New Albany with a population of 7,000 people was the largest community in the state and, like its more populous neighboring Kentucky city of Louisville, owed its location and growth to the falls of the Ohio River which provided a natural site for trade and commerce.

The New Albany & Salem Railroad was completed over the 35 miles of distance between those Indiana points named in its title in January 1851; but Indiana's one harbor on Lake Michigan, Michigan City, was the real goal. Service between these two termini, 288 miles apart, was begun on July 4, 1854. All of the line had been constructed by the New Albany & Salem Railroad, except the 27-mile segment between Crawfordsville and Lafayette, which had been completed in June 1852 to connect the former community with the Wabash and Erie Canal and acquired within the same month by the New Albany & Salem Railroad.

The charter of the New Albany & Salem Railroad permitted it to build anywhere within the State of Indiana, and this franchise was used to permit the construction of the Michigan Central Railroad across the northwestern edge of the state and so win its race in May 1852, by a single day, as the first eastern railroad to enter Chicago.

The New Albany & Salem Railroad failed in the panic of 1857, and was reorganized after foreclosure in the following year as the Louisville, New Albany & Chicago Railroad. This road played an important role in the Civil War, and the funeral train carrying the body of the martyred President Lincoln passed over its line between Lafayette and Michigan City en route to Chicago.

Changes in the corporate relationships of railroads that had previously provided the Louisville, New Albany & Chicago with access over friendly connections to the traffic of Chicago, Indianapolis, and Cincinnati led to traffic losses which occasioned a second receivership between 1868 and 1872. Between 1879 and 1882, the Louisville, New Albany & Chicago endeavored to correct this handicap by providing its own direct route between Chicago and Indianapolis which crossed

the Michigan City-New Albany line at the station later given the name of Monon that identifies the road itself. (Monon is an Indian word meaning swift running.) The branch into the popular resort with its sulfur springs at French Lick was built in 1886-1887.

A third reorganization followed the panic of 1893. A receiver was appointed in August 1896 and the company passed, after foreclosure, to the Chicago, Indianapolis and Louisville Railway Company on March 31, 1897. In July 1902, the Louisville & Nashville and the Southern Railway acquired 87 per cent of the stock of the Monon. The latter company prospered until the depression of the 1930's brought it into bankruptcy on Dec. 30, 1933. Its fourth reorganization was consummated on May 1, 1946.

JOHN W. BARRIGER,
President.

CHICAGO, MILWAUKEE, ST. PAUL AND PACIFIC RAILROAD COMPANY, incorporated March 31, 1927, was organized under the laws of Wisconsin in order to take over the properties of Chicago, Milwaukee and St. Paul Railway Company, a Wisconsin corporation (organized May 5, 1863, as the Milwaukee and Saint Paul Railway Company, "Chicago" having been added to its name Feb. 11, 1874), after receivership and mortgage foreclosure proceedings, culminating in sale of its property on Nov. 22, 1926; and reorganized after bankruptcy by amendment of charter but without change of name, effective as of Dec. 1, 1945. On June 29, 1935, the company had filed a petition for reorganization under Section 77 of the National Bankruptcy Act in the District Court of the United States for the Northern District of Illinois, Eastern Division; and on that date the court issued its order approving the petition as properly filed. Thereafter, in pursuance of a plan of reorganization certified by the Interstate Commerce Commission by order dated April 10, 1944, Finance Docket 10882, and confirmed by the district court by order dated Feb. 23, 1945, the company was reorganized by amendment of charter, the amendments being approved by order of the same court dated Nov. 26, 1945. In accordance, the property was vested in the reorganized company as of Dec. 1, 1945. The total capitalization was reduced from \$708,100,000 to \$558,100,000. Fixed interest bearing debt was reduced from \$300,800,000 to \$97,200,000. Contingent interest bearing debt was reduced from \$182,900,000 to \$116,400,000.

From its early days, the company's history records steady growth through the acquisition of smaller lines until a system developed, extending from Chicago and Milwaukee to Saint Paul, Kansas City, Mo., Omaha, and many other points in Wisconsin, Iowa, Minnesota, North Dakota, and South Dakota. As of Jan. 1, 1913, Chicago, Milwaukee and St. Paul Railway Company acquired the property of its subsidiary, Chicago, Milwaukee and Puget Sound Railway Company, which operated 2,081 miles of main and branch lines, extending from Mobridge, S. Dak., to Seattle and Tacoma, Wash. Subsequently, other lines were acquired, including the Idaho and Washington Northern Railroad, Big Blackfoot Railway Company, Tacoma Eastern Railroad Company, Puget Sound and Willapa Harbor Railway Company; Seattle, Port Angeles and Western Railway Company; Bellingham and Northern Railway Company, Milwaukee Terminal Railway Com-

pany, Gallatin Valley Railroad Company, and Chicago, Milwaukee and Gary Railway Company. The properties of the Chicago, Terre Haute and Southeastern Railway Company which had been operated by the Milwaukee company or its predecessors since July 1, 1921 under a 999-year lease, were conveyed to the Milwaukee company by deed dated Dec. 31, 1948. The lease was cancelled. The Milwaukee company deposited an amount equal to \$10 per share for each share of Terre Haute capital stock not owned by the Milwaukee, and under an agreement of Dec. 31, 1948, between the two companies the Milwaukee assumed obligation and liability in respect of the payment of principal and interest on the outstanding Terre Haute bonds.

Location and Mileage.—On Dec. 31, 1949, Chicago, Milwaukee, St. Paul and Pacific Railroad Company operated 10,671 miles of railroad, of which 9,842 were solely owned, 165 jointly owned, and 664 were operated under trackage rights. It operated within 14 states: Idaho, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Montana, Nebraska, North Dakota, South Dakota, Washington, and Wisconsin. Between Harlowton, Mont., and Avery, Idaho; and between Othello and Tacoma, Wash., 662 miles had been electrified.

Equipment.—On Dec. 31, 1949, the company owned 910 steam, 49 electric and 185 diesel-electric locomotives; 59,522 freight cars; 1,086 passenger cars, 17 rail motor cars, 1 tugboat, 4 car barges, and 3,223 units of company service equipment. Diesel-electric locomotives were performing 37 per cent of freight operation; 50 per cent of passenger operation; and 50 per cent of yard switching. Further dieselization was planned.

Traffic and Characteristics of Territory.—Serving as it does the Northwestern states, agricultural production (including animals) is normally important to the road, accounting in 1949 for approximately 26 per cent of freight revenue. Wheat from the spring wheat regions of Minnesota, South Dakota, and Montana, is carried eastward to Minneapolis and St. Paul where it is made into flour and distributed. Corn, oats, barley, and rye, cattle from the Northwestern region, and hogs and meat products from the corn belt are important traffic items. While agricultural products are exceeded by the manufactures and miscellaneous classification, which produced 41 per cent of freight revenue in 1949, the most important single revenue-producing commodity was bituminous coal. There is a large production of bituminous coal originating, for the most part, in Indiana, which is distributed at points along the railroad or delivered to connecting railroads. This coal competes with other bituminous coal originating in Southern Illinois, Kentucky, and West Virginia and other eastern origins. Lumber, refined petroleum products, gasoline, manufactured iron and steel, including pipe and fittings, agricultural implements, cement, wood pulp, canned food products, liquors, and malt comprise other major commodities carried.

The number of passengers carried in 1949 was 8,102,277, the total of passenger-miles was 874,444,524, and the average rate per passenger-mile was 2.22 cents. The company's better-known trains are the *Olympian Hiawatha* and the *Columbian*, operating between Chicago and Seattle and Tacoma, Wash.; morning and afternoon *Twin Cities Hiawathas* operating between Chicago, Mil-

waukee, St. Paul, and Minneapolis; the *Midwest Hiawatha* operating between Chicago, Ill., and Des Moines, Iowa; Omaha, Nebr.; Sioux City, Iowa; and Sioux Falls, S. Dak.; and the *Pioneer Limited* which is a long-established overnight train between Chicago and Minneapolis and St. Paul.

Financial.—On Dec. 31, 1949, the balance sheet showed the following: investment in transportation property less depreciation, \$525,900,000; total investments, \$568,400,000; current assets \$89,000,000; total assets, \$662,900,000; capital stock, \$324,500,000; long-term debt, \$228,900,000; current liabilities, \$44,800,000; net working capital, \$44,200,000; earned surplus, \$59,400,000; and total liabilities, \$662,900,000.

Revenues and Expenses.—Operating revenues for the year 1949 were \$238,000,000; operating expenses were \$202,100,000; net railway operating income was \$10,900,000; and net income was \$4,500,000. The average number of employees in 1949 was 35,131. Wages and payroll taxes were \$140,500,000, equal to \$4,000 per employee, and were equivalent to 59 per cent of the operating revenues.

The year 1950 marked the opening of the railroad's second century of service. Operation of the original predecessor company began on Nov. 20, 1850, with the running of a train a distance of five miles from Milwaukee to Wauwatosa, Wis.

C. H. BUFORD, *President*.

CHICAGO, ROCK ISLAND AND PACIFIC RAILROAD COMPANY. This company (CRI & PRR Co.) was incorporated December 16, 1947 under the laws of Delaware, term of corporate existence not limited. The company is successor under a plan of reorganization, confirmed May 23, 1947, to The Chicago, Rock Island and Pacific Railway Company. To the new company was transferred all properties of the earlier one, together with its subsidiary companies. The transfer was effective January 1, 1948, and on that date the new company commenced operations.

The company operated approximately 7,620 miles of road in 1950 (known as the Rock Island Lines), of which about 7,157 miles were owned and 463 miles were trackage rights. In addition, it operated 651 miles of second and other main tracks. It operated in 14 states, its general system radiating from Chicago through Illinois, Iowa, Nebraska, Kansas, and Colorado to Denver and Colorado Springs; north through Minnesota to St. Paul and Minneapolis; southwest via Kansas City, Mo., through Oklahoma and New Mexico to Santa Rosa, N. Mex.; south through Texas to Fort Worth, Dallas, Houston and Galveston; and from Memphis, Tenn., westward through Arkansas and Oklahoma to Tucumcari, N. Mex. Rounded off to the nearest final digit, the mileage of these principal main lines was as follows: Chicago, via Kansas City, to Santa Rosa, 1,168; Davenport, Iowa, via Des Moines to Colorado Springs and Denver, 979; Herington, Kans., to Fort Worth, Dallas, Houston, and Galveston, 775; Burlington, Iowa, via Cedar Rapids, to Minneapolis, 366; Memphis, Tenn., via Little Rock and Oklahoma City to Tucumcari, 874; St. Louis, Mo., to Kansas City, Mo., 295. Principal secondary main or branch lines were: Vinton, Iowa, to Sioux Falls and Watertown, S. Dak., 420; McFarland, Kans., to Belleville, Kans., 103; Little Rock, Ark., to Eunice, La., 309.

During an intensive improvement period, Jan. 1, 1938 to Nov. 30, 1949, a total of 385,841 tons of new rail was laid, the equivalent of some 2,160 track miles. As part of the same improvement program, as of Dec. 31, 1949, 2,505 miles of the system had been equipped with automatic block signals and an additional 830 miles with centralized traffic control.

The principal affiliate companies are Peoria Terminal Company, which is a terminal company operating at Peoria, Ill.; Peoria and Bureau Valley Railroad Company, which owns a line of railroad about 46 miles long between Bureau and Peoria, Ill.; Burlington-Rock Island Railroad Company (50 per cent owned by the CRI & PRR Co.) which owns almost 212 miles of railroad in Texas over which the CRI & PRR Co. operates between Dallas, Houston, and Galveston; and The Rock Island Motor Transit Company, a wholly-owned trucking subsidiary, which operates 5,134 route miles in 11 Midwest states, with 620 pieces of equipment. At Santa Rosa, N. Mex., the company ties in with the Southern Pacific Railroad and, jointly with that company, operates through service to Arizona and California points.

Passengers carried in 1949 were 12,000,000. The total of freight traffic handled was 38,500,000 tons of which the products of mines and forests constituted 15 million tons; manufactures, 12 million tons; agricultural products, 10 million tons; and livestock and their products, 1 million tons.

J. D. FARRINGTON,
President.

CHICAGO, University of. An institution of higher education and research, located at Chicago, Ill.; founded in 1890; privately endowed; coeducational and nondenominational.

The university includes the following departments: the college; the four divisions—humanities and the social, biological, and physical sciences; and the six professional schools—Divinity, Law, Business, Graduate Library, Social Service Administration, and the Medical School.

In 1942, after five years of experimentation in University High School and 12 years with the "Chicago Plan," collegiate work was relocated. Students are admitted to the college at the end of the sophomore year of high school for a four-year program of general education; on its completion, the bachelor's degree is granted. Qualified students may enter at any level and be placed in the appropriate classes through a system of placement tests given upon entrance to determine the educational achievement of each student in relation to the college's definition of general education. Students satisfy degree requirements by passing 14 comprehensive examinations, or by being excused through the placement tests. The program of work for the master's degree is a three-year program. Both master's degree and that of doctor of philosophy are granted in the humanities, and the biological, physical, and social sciences.

William Rainey Harper, who had occupied three separate chairs of instruction at Yale University, accepted the presidency in 1891. His first faculty comprised 120 men and women, including nine men who left the presidencies of higher institutions to accept teaching posts with the new university before any student had registered for classes. In 1950, the faculty numbered 1,000.

Between the time of Dr. Harper's death (1906) and 1950, the university had five presidents. The first four were Harry Pratt Judson, Ernest De Witt Burton, Max Mason, and Robert Maynard Hutchins. At the time of his acceptance of the presidency in 1929, Mr. Hutchins was the youngest university president in the United States. The educational policies enunciated at his inauguration and since put into effect made him a vigorous leader in educational improvements; his analyses of world affairs made him internationally known. In June 1945, the trustees changed Mr. Hutchins' title to chancellor. On the same date, Ernest Cadman Colwell became president, responsible to the chancellor for the educational operations of the university.

The decision which brought the atomic bomb research to the university was made by Mr. Hutchins. The self-sustaining nuclear reaction, in the world's first "pile" under the west stand of Stagg Field, on Dec. 2, 1942, was the first product of the decision. Before World War II was over, Chancellor Hutchins gathered the chief men of his undertaking into three new research institutes for peacetime nuclear, biological, and metal research. Included among the men were two Nobel Prize winners, Harold Clayton Urey and Enrico Fermi. James Franck, professor of chemistry, became a third Nobel Prize winner on the university staff. With a \$12,500,000 program, the three institutes constituted the largest privately-supported atomic research undertaking in 1950. The United States Navy provided most of the cost of the \$2,200,000 synchrocyclotron; and, as of 1950, industrial corporations were the source of \$650,000 a year in support of the program. The Argonne National Laboratory, near Chicago, is also operated by the university, under a contract with the United States Atomic Energy Commission; 29 midwestern institutions, including the university, cooperate in the research program.

The university's medical and biological research center is unique. The medical school is the only school in the United States with a staff devoting full time to medical teaching and research, and engaging in no practice except in the university's clinics.

CHICAGO AND ALTON RAILROAD, a pioneer western railroad. Its first segment was chartered in 1847, and it was completed from Chicago to Kansas City, Mo., in 1879. In 1947 it became part of the Gulf, Mobile and Ohio Railroad.

CHICAGO AND NORTH WESTERN RAILWAY SYSTEM, a railroad system comprising the Chicago and North Western Railway Company and the Chicago, St. Paul, Minneapolis and Omaha Railway Company. The C&NW assumed control of the latter in 1925 through ownership of capital stock. The system serves Illinois, Wisconsin, the upper peninsula of Michigan, Minnesota, Iowa, North Dakota, South Dakota, Nebraska, and Wyoming. The double-track Chicago-to-Omaha line connects with the Union Pacific, forming part of a transcontinental route. The parent company (C&NW) was organized June 7, 1859, by the purchasers of the Chicago, St. Paul and Fond du Lac Railroad, which had been sold at foreclosure on June 2 of the same year. Following this there was a series of consolidations and acquisitions, of which the

most important were the Galena and Chicago Union Railroad (1864), the Peninsula Railroad of Michigan (1864), the Elgin and State Line Railroad (1883), the Chicago, Milwaukee and North Western Railway (1883), the Sioux City and Pacific Railroad (1901), and the Fremont, Elkhorn and Missouri Valley Railroad (1903).

CHICAGO GREAT WESTERN RAILWAY COMPANY, a system operating in Illinois, Iowa, Minnesota, Nebraska, Kansas, and Missouri. The company had its beginning with the charter issued in 1854 to the Minnesota & Northwestern Railway; but no construction was undertaken until 1884, when Alpheus Beede Stickney, founder and first president of the Chicago Great Western, began construction of its first unit of track, 109 miles from Lyle to St. Paul, Minn. Subsequently the road was extended by construction, through consolidation, and by acquisition. Train service commenced to Chicago in 1887, to St. Joseph and Kansas City, Mo., in 1889, and to Omaha, Nebr., in 1904. Its main line, then known as the Chicago, St. Paul & Kansas City Railway (company, incorporated in 1886) and extending from Des Moines, Iowa, to St. Joseph, Mo., was built in 1887 and 1888. The present name was adopted July 1, 1892.

CHICAGO HEIGHTS, city, Illinois; 1 Cook County; altitude 694 feet; 27 miles south of Chicago; on the Chicago and Eastern Illinois Railroad and having freight service over several other railroads via the Chicago Heights Terminal Railroad. The city has extensive industries. There is a Carnegie public library. First settled at a junction of trails about 1833, Chicago Heights became a city in 1901. Government. Pop. (1950) 24,700.

CHICAGO NATURAL HISTORY MUSEUM (formerly FIELD MUSEUM OF NATURAL HISTORY), founded by the famed merchant, Marshall Field,¹ in 1893 with a gift of \$1,000,000, which was augmented by contributions from other Chicagoans.

The museum is divided into four departments—anthropology, botany, geology, and zoology, each with many specialized divisions. The collections assembled in each of these have raised the institution during its comparatively short span of existence to a rank rivaled only by three other natural history museums in the entire world—those in Washington, New York, and London, all established many years earlier. In many fields, Chicago Natural History Museum possesses collections not duplicated anywhere else. It has been built up through the years by the work of scientists who have conducted more than 600 expeditions in nearly all parts of the world. Concurrently with the collecting and preparation of exhibits, a vast amount of diversified research has been carried on which has expanded the sum total of human knowledge.

In addition to the four scientific departments, the museum maintains an important library, operates a publishing plant to produce scientific books and periodicals, and conducts a broad program of service to the public. Two separately endowed foundations within the museum are devoted to the science education of children. One of these keeps a constant succession of hundreds of miniature traveling natural history exhibits in circulation among all the schools of Chicago; the other

provides extension lectures, films, slides, and other aural and visual facilities.

CLIFFORD C. GREGG.

¹At his death in 1906, Field bequeathed \$8,000,000 more to the museum; total endowment today is approximately \$12,500,000.

CHICHEN ITZA, *chê-chân' êt-sâ'*, the largest archaeological zone in Yucatán, Mexico, and one of the most important in the New World, situated 72 miles east-southeast of Mérida, with which it is connected by a highway.

History.—Chichén Itzá originated as a northern outpost of the Maya Old Empire and was settled by the Itzá people in 514 A.D. (S. G. Morley's chronology; see end of article) near two great *cenotes*—natural wells supplied with underground water—so necessary to life in this semiarid region. The very name Chichén Itzá means "at the mouth of the well of the Itzá," a reference to the Sacred Well. Abandoned in 692, the site was reoccupied by the Itzá in 987; this time jointly with a Mexican (possibly Toltec) group under Kukulcán, who was perhaps later deified as the feathered serpent. A renaissance of Maya civilization took place, and in 1007 the three great cities of the New Empire, Chichén Itzá, Mayapán, and Uxmal, formed the League of Mayapán. The culture of Chichén Itzá and Mayapán, which was settled from Chichén Itzá, was Maya-Mexican, while the beautiful buildings at Uxmal show a more purely Maya origin. During the period of the League of Mayapán, Chichén Itzá, the holy city of the Maya, with its Sacred Well, was the object of pilgrimages from all parts of the Maya world and beyond. El Castillo, the Ball Court, the Temple of the Jaguars, and the Observatory date from this period.

Rivalry among the cities, however, led to a civil war in which Chichén Itzá was subjugated (1194) by Mayapán, which employed Mexican mercenaries. The period of Mayapán's domination was ended by a revolt of the Maya lords under the leadership of Uxmal, and Mayapán was sacked (1441), after which the New Empire civilization declined and the great cities were abandoned, the Itzá returning southward to settle around Lake Petén, now in Guatemala.

The principal excavations and reconstructions at Chichén Itzá were conducted by the Mexican Ministry of Public Education, and by the Carnegie Institution of Washington, D.C. under the direction (1924–1940) of Sylvanus Griswold Morley.

Principal Buildings.—Most of the buildings rest on earth-filled terraces faced with light gray stone; the columns and many of the walls are sculpted in bas-relief or—in the case of other (generally older) walls—are decorated by the fitting together of innumerable small pieces of stone to form geometric patterns or faces of the all-important rain god Chac, with his "elephant trunk" nose curling out from the wall in a single piece of stone. In their original condition the bas-relief sculptures were painted brilliant greens, reds, and yellows, so that the appearance of the city must have had an almost barbaric splendor.

El Castillo (The Castle), or the Temple of Kukulcán, is a steep, truncated pyramid, 184 ft along the base of each of its four sides, 84 ft high, with a two-chamber temple on top. The pyramid rises in a series of narrow, stone-faced terraces which are divided on each of the four sides by a broad stairway with wide balustrade.

the balustrades of the main (north) stairway and in two huge serpent heads on the ground, with open mouths and protruding tongues.

This structure was built over an older pyramid. The latter is reached by a tunnel which follows an excavated portion of the stairway of the inner pyramid to its top. Here, under the platform of the outer pyramid, is the chamber containing the celebrated Red Tiger Throne, a monolithic limestone jaguar painted red and inlaid with jade disks to represent its eyes and fangs.

The Ball Court consists of two immense, parallel, smooth stone walls, 274 feet long and 20 feet apart; the court being open at two ends. The object of the game was to use any part of the body except the hands to knock a rubber ball through a stone ring, two of which, entwined with serpents, are set opposite each other high in the center of the walls. Bas-relief sculptures along the base of the walls depict various richly attired dignitaries, one of whom has been depicted, facing a disk bearing a death's head.

The Temple of the Jaguars stands above the south end of the Ball Court. Within are two chambers, the inner one notable for its wall paintings showing scenes of daily life. There are carvings of warriors attacking a town, women at work, and utensils very similar to those inhabited by the modern Maya of Yucatán.

The Sacred Well, into which pilgrims cast sacrificial offerings, including human beings, is a deep, circular hole, 165 feet in diameter, and about 100 feet deep; the depth of the water varying from 15 to 35 feet. The second well, the *stoloc* (small lizard) *cenote*, of about the same dimensions, is in the second division of the zone.

The Temple of the Warriors is a magnificent structure, a series of terraces with a walled, but roofless, temple on top. It is ascended by a wide stairway and entered between two lofty columns in the form of serpents. At its foot is a veritable forest of four-sided columns composed of square stone blocks laid one on the other and beautifully sculpted with human figures. Under the Temple of the Warriors are two earlier structures; the first a small pyramid closely resembling El Castillo in shape, the second another temple containing a chamber in which are frescoes and a number of columns like those at the foot of the outer temple, with the difference that these are so well preserved that their coloring is distinct and affords a clue to the original appearance of those outside. While the other temples mentioned are roofed with stone and earth by means of corbel arches, the material used to roof this temple and to cover the columns below it remains a matter of conjecture.

The Observatory (or El Caracol), perhaps the most interesting structure in the entire zone, was probably used as an astronomical observatory. It is a round tower 22 feet in diameter, with a dome-shaped top, 24 feet high overall. The tower rests on a smaller terrace which in turn rests on a larger one 208 feet long, 150 feet wide, and 17 feet high. Both are ascended by wide stairways with balustrades of entwining serpents. In the center of the tower is an immense column of stone blocks which is surrounded by two circular walls, each penetrated by four doorways. There is also a low, winding stairway (caracol, in Spanish) which gives access to the upper part.

The Nunnery (Casa de las Monjas), a large

building of several rooms, probably a palace, rests on a terrace 32 feet high, and is reached by still another wide stairway. The most interesting building nearby is the small El Templo (The Temple) on the east side at ground level. Its exterior is covered with an incredibly intricate design of small pieces of fitted stone, the dominant motif being a repetition of faces of the rain god Chac.

Heaps of ruined mounds, fallen walls, and sculptured blocks, as well as dozens of other buildings of lesser interest, more or less well preserved, scattered over the area show that the completely ruined part of the city is vastly larger than the part still standing.

CHICHESTER, chích'is-tēr, Arthur, BARON CHICHESTER OF BELFAST, English administrator; b. Raleigh, Devonshire, England, May 1563; d. Feb. 19, 1625. He was educated at Exeter College, Oxford, where he matriculated on March 15, 1568. In 1588 he was captain of one of the English ships sent against the Spanish Armada. He was probably on Sir Francis Drake's last voyage in 1595, and in 1596 and 1597 participated in military operations against Spain.

Robert Devereux, 2d earl of Essex, named him governor of Carrickfergus, Ireland, in 1599, and he later played a big role in campaigns against the feudal lords of the country and in the making of policy to be used in governing Ireland. On Feb. 3, 1605, he assumed his duties as lord deputy of Ireland. He abolished traditional privileges of the native lords and made their dependents subjects of the king of England. At the instigation of James I he tried to decrease the influence of the Roman Catholic church in Ireland. The persecutions involved in carrying out this plan were relaxed in 1607 on the advice of Chichester. However, his ideas about dividing the lands of Ulster, abandoned by their Irish lords, were not followed. Chichester wanted the natives to benefit first in such land grants, the English and Scottish planters to share any surplus. In 1614 he was again urged to take measures against increasing Roman Catholic influence. Recalled later that year, he was restored to favor in 1616, being appointed lord treasurer of Ireland.

CHICHESTER, chích'is-tēr, municipal borough, England; county seat of West Sussex, 16 miles east-northeast of Portsmouth. It is well built and has wide streets. Its old wall, most of which is still standing, is lined with elms and gives the town a very picturesque appearance. The cathedral is chiefly Early Norman and was built mainly between about 1090 and 1123. It has one of the most graceful spires in the country, and a detached bell tower, Perpendicular in style, which is the only one still standing in England. There is also a fine octagonal market cross built about 1500.

The site of Chichester was known as Regnum during the Roman occupation, and was the headquarters of Vespasian. It was captured by the Saxons in the 5th century, and renamed Cissacester for the Saxon king, Cissa. It was important throughout the Middle Ages and during the great civil war changed hands three times in 13 months (1642-1643). Pop. (1951) 19,110.

CHICK-PEA, the popular name of *Cicer*

arietinum and other plants of the same genus cultivated in Asia, Latin America, and around the Mediterranean. They are leguminous plants of the pea family well suited to dry climates, and produce a short puffy pod with generally two small wrinkled seeds, eaten boiled or roasted.

CHICKADEE. See **TITMOUSE**.

CHICKAHOMINY, *chik-ä-höm'i-ni*, river in eastern Virginia, about 90 miles in length. It is an affluent of the James and runs parallel to it for many miles from its source 16 miles northwest of Richmond. Many engagements of the Civil War took place along its course.

CHICKAMAUGA, *chik-ä-mò'gä*, **Battle of**, fought near Chickamauga Creek in northwest Georgia on Sept. 19-20, 1863. Chickamauga, a major battle and a Federal defeat, was indecisive in terms of the campaign of which it was a part. The size of the armies and the intensity of the fighting, however, made it one of the famed battles of the Civil War. It was outstanding for military reputations won and lost.

The campaign opened in early summer of 1863, with the Federal and Confederate armies facing

general, Braxton Bragg, had had considerable experience in independent command and was aggressive in spirit. His operations, however, were inclined to display disorganization and his relations with his subordinates left much to be desired. Both Rosecrans and Bragg suffered from that lack of adequate staff that characterized all the armies of the war until the final year. Staff is important for the gaining of intelligence and for communication. The course of the fighting at Chickamauga was conditioned by failures both of intelligence and communication, particularly in the Federal army.

What has been called the campaign of Chickamauga opened on June 24, 1863, when Rosecrans moved out of Murfreesboro, with Chattanooga as his objective. For weeks, as Gen. Robert E. Lee drove northward from Chancellorsville, Henry Wager Halleck, general in chief in Washington, had urged Rosecrans to take the offensive to put pressure on the Confederate forces that, in effect, guarded Lee's rear. At the same time, Rosecrans had complained of lack of men and supplies. Once in motion, however, he directed a brilliant campaign of maneuver. With well-conceived feints and flanking marches he forced his adversary without a battle out of southern and eastern Tennessee and into northwestern Georgia. In the early weeks of the campaign Bragg had been handicapped by a shortage of men, his army having been reduced to provide reinforcements for the defense of Vicksburg which fell on July 3, nine days after Rosecrans began to move. As Bragg retired, his army grew as troops no longer needed in the Vicksburg area were added to his force. In spite of Bragg's growing strength, Rosecrans forced him back by skillful maneuver and on September 9 entered Chattanooga without a battle. It was a great achievement, for Chattanooga, a railway center binding together the Confederate east and west, possessed a strategic importance if anything greater than Vicksburg.

Rosecrans believed Bragg to be on the run and decided to pursue and, if possible, to destroy him. But the Confederates were far from defeated. President Jefferson Davis, aroused by Southern reverses at Gettysburg and Vicksburg, made strenuous efforts to have Bragg check and throw back the Federal thrust at Chattanooga. He arranged for reinforcements for Bragg, even detaching Lieut. Gen. James Longstreet's corps from Lee's Army of Virginia and sending it by rail to Bragg. Because of the scarcity of railroads in the South, Longstreet's men had to come from Virginia by way of Charleston, S. C.

The actions that followed the occupation of Chattanooga were conditioned by the nature of the terrain about that town. The city lies in the western edge of the broad Appalachian mountain system that in the 1860's divided the Confederacy into two parts. The mountains in this region consist of rugged parallel ridges covered at the time of the Civil War by forests of scrub oak and pine, broken here and there by small clearings where isolated farmers eked out a subsistence. Two of these homesteads, those of the Widow Glen and of Snodgrass, achieved a place in history by being on the Chickamauga battlefield. Widely separated gaps permitted main highways to cross the ridges, though some mountain roads surmounted their crests. Uplands and woods made the country difficult and, to make matters worse, neither Federals nor Confederates had adequate maps.

Rosecrans, in possession of Chattanooga and believing Bragg to be retreating eastward along

another near Murfreesboro, Tenn. In June 1863, Lee, after his victory at Chancellorsville in Virginia, was advancing northward to invade Pennsylvania. Grant, on the Mississippi, was striking toward Vicksburg, Miss., the last important Confederate crossing point for supplies from Texas and Arkansas. Maj. Gen. William S. Rosecrans, commander of the Union Army of the Cumberland at Murfreesboro, knew well the art of war but lacked the force of character to exercise leadership in an emergency. The Confederate

the railway that led to Charleston, ordered on September 9 a "general pursuit." The Federals planned to continue the feinting and flanking tactics that had worked so well in the more level country west of the ridge that separated Chattanooga from central Tennessee. Rosecrans despatched his three corps, under major generals Alexander McD. McCook, Thomas L. Crittenden, and George H. Thomas respectively in a general easterly and south-easterly direction through mountain passes separated from one another by many miles. When Rosecrans made this decision to divide his army, he did not know the location of Bragg's force. The offensive spirit that dominated the Rosecrans headquarters is illustrated by the orders sent to Crittenden, whose corps was advancing along the railroad: "Be ready to attack the enemy with the utmost vigor." Three days after the "pursuit" had begun each corps had virtually reached its first designated objective and Rosecrans' army was spread over 50 miles of hilly, wooded country connected only by primitive roads. Only Thomas, advancing near Chickamauga Creek, had met opposition. On September 11 a strong Confederate force had attached Thomas' advance guard and had driven it back on the main body. Informed of this action, Rosecrans suddenly became aware that he faced a situation vastly different from the one he had assumed when he made his plans.

Bragg, whose army had been greatly augmented, after evacuating Chattanooga had retired into the rough country as far as Chickamauga Creek where he stopped and made ready to fight. Some of his troops were newly arrived and many of his subordinates were strangers to one another. Longstreet's corps was on the way and did not report for action until the night of September 19. With that addition, Bragg had a force of about 73,000 men. Rosecrans opened the battle with a nominal strength of about 55,000, of whom 10,000 were mounted.

On September 12 Bragg had the opportunity to attack the dangerously extended army of his adversary, one corps at a time. His failure to do so was a military blunder equal in magnitude to that of Rosecrans in rashly dispersing his troops in mountainous country without first being sure of his enemy's whereabouts and whether or not he was in retreat. Rosecrans, grasping the danger of his situation, ordered McCook and Crittenden to hurry their troops to positions beside Thomas. They concentrated through Rossville Gap through which ran the highway from Chattanooga to Lafayette, Tenn. On September 18 the Federal army, wearied by forced marches, stood united with its back to Missionary Ridge facing Bragg concealed in the woods on the eastern side of Chickamauga Creek. Rosecrans had rectified his error, but he was near exhaustion when the concentration was completed.

On September 19 the Federal line, running more or less along the Chattanooga-Lafayette road, consisted of Thomas on the left (north), Crittenden in the center, and McCook on the right (south). Bragg seized the offensive, directing assaults primarily against Thomas with what Thomas believed to be the intention of driving back the Federal left to open the way for a flanking movement to Rossville Gap and the Federal rear. September 19 was a day of hard and often confused fighting in woods and thickets. Civil War tactics still called for fighting in close order formation, a style much hampered by wooded

terrain. Darkness brought an end to a bloody contest in which neither side had gained any decisive advantage. Rosecrans prepared for defensive battle on the following day, estimating correctly that his enemy outnumbered him. Even as the fatigued Federal commander made his plans, Longstreet arrived with his corps of veterans from Gettysburg. Bragg placed him on the Confederate left.

In the forenoon of September 20 the Confederates again forced the fighting. Again Thomas found himself hard pressed. Rosecrans, to prevent his army from being outflanked on the left, sought to transfer units from the Federal center and right so as to provide Thomas with the means to hold. A series of unfortunate occurrences prepared the way for catastrophe. The first of these was the failure of McCook to obey an order from the commanding general to send a particular unit to Thomas, a failure that multiplied Thomas' worries. Then, as the battle roared to a climax in the latter part of the morning, a unit sent to the aid of the Federal left became confused by the terrain and the situation and took up a position where it was of no immediate use. Finally, erroneous information came to Rosecrans' headquarters, resulting from a Federal officer's hasty and incomplete observation, that a gap existed in the center of the Union line. Up to this time, the Federal center and right had not been seriously engaged. Rosecrans, acting hastily and without investigation, issued an order to a unit commander that gave the subordinate no explanation of why the order was issued or discretion, if it should prove to be unwise in view of his immediate local situation. As a result the subordinate moved out of the line leaving behind a genuine gap.

Almost immediately Longstreet struck the Federal center. The triumphant Confederates poured through the gap, at the same time attacking the right. McCook's corps and that of Crittenden fell back in rout along Dry Valley Road. Rosecrans, who had placed his headquarters at Widow Glen's behind McCook, was swept along in what became a stampede. The commanding general rode headlong through McFarland's Gap to Chattanooga to prepare a last ditch defense of his base. Completely unnerved, he wired Lincoln that his force had suffered disaster.

In sending the message Rosecrans had again acted without adequate information. His later reputation would have been better had the commanding general personally undertaken to do what his chief of staff, Brig. Gen. James A. Garfield, asked and got permission to do. Vague information coming to Chattanooga suggested to Garfield that Thomas still fought in his original position. Garfield, riding back to the battlefield, verified the report and joined Thomas at the latter's headquarters on Snodgrass Hill. When the Federal center and right gave way, Thomas had formed his forces in a horseshoe so placed as to protect both his flanks and to command every vital road. He held his ground until night came, thereby winning the designation, "Rock of Chickamauga." Garfield informed Rosecrans of the situation. When the fighting ended, Rosecrans, resuming control of the army, ordered Thomas to fall back to Rossville Gap where defensive positions would be very strong.

So the Chickamauga campaign, that had begun so auspiciously for the Union, ended with the Federal army confined in Chattanooga besieged by

Bragg. Rosecrans, so shaken as to be unable to function effectively, permitted the Confederates to close all the main supply routes from Tennessee. The siege, therefore, promised Bragg the possibility of complete success. Such supplies as the desperate Federals managed to get into Chattanooga had to be hauled over rough mountain roads that crossed the crest of the ridge lying west of Chattanooga. The Army of the Cumberland to which Rosecrans was unable to bring order faced starvation.

Lincoln acted to remedy the situation by designating Grant, conqueror of Vicksburg, commander of all the Federal armies save one, in the western theater. Grant promptly relieved Rosecrans, putting Thomas in his place. The new commander at Chattanooga, demonstrating as much ability in cantonment as in the field, re-established order, improved the supply position, and held until Grant could send reinforcements and come in person to establish his headquarters at Chattanooga.

The battle had shattered the reputations, not only of Rosecrans but of McCook and Crittenden whom Rosecrans had relieved before the end of the battle. Also dissension, after the battle, demoralized the Confederate force. Bragg's handling of the engagement had caused him to forfeit the confidence of all his chief subordinates. They made bitter reports to President Davis who hurried from Richmond to investigate the situation in person. He found Bragg as critical of his generals as they were of him. Though the president still retained confidence in Bragg, he offered the command to Lieut. Gen. William J. Hardee and to Longstreet. Both refused; and Davis declined to appoint Gen. Joseph E. Johnston whom Longstreet suggested. So Bragg retained his post. He commanded the army when Grant moved out of Chattanooga in December and smashed his force.

Chickamauga was one of the bloodiest battles in a war characterized by heavy losses on the battlefield. Rosecrans lost in killed, wounded, and missing more than 16,000 men, Bragg about 18,000. For troops actually engaged, this represented a percentage of 33 for each side.

CHICKAMAUGA AND CHATTA-NOOGA NATIONAL MILITARY PARK, Georgia and Tennessee, oldest and largest of the national military parks, was established to preserve the scene of the Civil War battles fought for control of Chattanooga, Tenn., and as a memorial to both the Northern and Southern forces who fought so heroically in the battles. Located at a gap in the mountains through which flows the Tennessee River, Chattanooga was an important railroad junction at the time and a key to the communications system of the Southern Confederacy.

The park is composed of separate areas, the more important of which are Chickamauga Battlefield; Point Park and the Battlefield of Lookout Mountain, and Orchard Knob, in Chattanooga; a chain of small reservations located on Missionary

Ridge; and Signal Point on Signal Mountain. The park contains approximately 8,000 acres of federal land, about 6,300 of which are in Georgia, the remainder in Tennessee.

From the terrace of an observatory and museum at Point Park on the north end of Lookout Mountain, high above the winding Tennessee River, park visitors obtain a comprehensive view of the Battlefield of Chattanooga. Markers identify the more important troop positions, and maps are available indicating the natural and historic features of interest. This structure is a memorial to Adolph S. Ochs, publisher of the *Chattanooga Times* and the *New York Times*. He was a leader in the movement that resulted in establishment of the park and was responsible for the acquisition of considerable land on Lookout Mountain for park purposes.

From its establishment in 1890 until 1933, when it was transferred to the jurisdiction of the National Park Service, the park was administered by the War Department.

CHICKAREE, chīk'ā-rē. See **SQUIRREL**.

CHICKASAW, chīk'ā-sō, a small American Indian tribe of Muskogean stock, closely related to the Choctaw and speaking a different dialect of the same language. The original homeland of the Chickasaws during historic times was northern Mississippi and adjacent parts of Alabama and Tennessee. They were an energetic, warlike people; but although of marked ability, they were—because of their relative remoteness from white settlements—slower than their Choctaw kinsmen to adopt civilized customs.

Their first contact with Europeans was with the De Soto expedition, which spent the winter of 1540-1541 near their villages and was badly crippled in a battle with their intrepid warriors the following spring. For the next century and a half they were almost undisturbed. Then at about the year 1700 English traders penetrated to their country and the French began making settlements near the mouth of the Mississippi. The Chickasaws allied themselves with the English and fought the Choctaws and other tribes under French influence; but when the American Revolution broke out, some of their warriors served in the American armies. They made their first treaty with the United States in 1786 at Hopewell, on the Keowee River in South Carolina.

During this period they received considerable admixture of white blood from English and Scotch-Irish traders and others who settled in their country and married Chickasaw women. In 1819 Presbyterian missionaries began to work among them. A careful estimate made in 1822 set their population at 3,625; they were then living in eight settlements, farming and raising livestock. Some of them, especially those with mixed blood, had acquired Negro slaves.

But the pressure of the white frontier forced them to cede outlying tracts of their land during the early 1800's. Finally in 1832 they agreed to surrender the remainder and remove to the west of the Mississippi as soon as they could find a suitable location. They sent out several exploring parties without success, and the government became impatient. Finally in 1837 they were induced to sign a treaty with the Choctaws, by which for a consideration of \$530,000 they obtained the right to join that tribe.

The Choctaws at that time owned the southern half of Oklahoma, but their settlements—made after their own removal a few years before—were in the eastern portion of their domain. The Chickasaws at first made their homes among them, but eventually formed a district of their own farther west. They made some ineffectual efforts to build schools and set up a local government in their district, but mainly they marked time, unwilling to be merged with the larger tribe. A separation was finally effected in 1855, though the two peoples continued to own their land in common.

The Chickasaws then created an independent government with a governor, a legislature of two houses, and a system of courts. They established neighborhood schools and boarding schools, and even encouraged attendance by a regular payment to the parents. At a place they named Tishomingo they erected a brick capitol, later replaced by a sturdy stone building now used as a county courthouse. They became a Christian people. Some of their Presbyterian churches have held centennial celebrations recently.

With the Choctaws they joined the Confederacy in the Civil War. As a punishment the two tribes were to cede more than one third of their territory, the tract lying west of the Chickasaw district. They were to receive payment for this cession if they would grant citizenship to their former slaves; otherwise the government would colonize the Negroes elsewhere and use the money for them. The Chickasaws steadfastly refused the grant of citizenship, but the United States failed to carry out its part of the contract; hence the freedmen remained in their country with no legal status.

Some of the richest agricultural land in Oklahoma lay in the Chickasaw district. This fact and the small tribal population invited white immigration after the Civil War—men who came in as railroad builders, town builders, cattlemen, and farmers. Some became intermarried citizens, others paid a tax to the tribe, more were simply intruders. When the first federal census was taken in 1890, it enumerated 48,421 white people, 3,676 Negroes, and only 5,223 Indians. All this alien population was without government or schools or legal land tenure.

The federal government accordingly liquidated the affairs of the tribe. In the division of property each citizen received an allotment of land varying from 160 to 4,165 acres according to its quality, and \$1,425 in cash. Allotments were also made to the freedmen, but the Chickasaws protested and carried their case to the courts; and the United States Government was required to pay them for the land thus misappropriated.

The Chickasaws became citizens of the United States, and at statehood in 1907, citizens of Oklahoma. Many have become prominent. Johnston Murray, who became governor of the state in 1951, is of Chickasaw descent. A few fullblood settlements may still be found in remote places in south central Oklahoma. See also CHOCTAW.

Consult Wright, Muriel H., *A Guide to the Indian Tribes of Oklahoma* (Univ. of Oklahoma 1951).

ANGIE DEBO,
Librarian, Oklahoma Agricultural and Mechanical College.

CHICKASAW, chik'a-só, city, Alabama; in Mobile County; 6 miles north of Mobile; altitude 40 feet. It is situated on Chickasabogue

Creek, an affluent of the Mobile River, and is connected with Mobile Bay by a 25-foot channel. Chickasaw is served by the Southern and the Alabama, Tennessee and Northern railroads, the Terminal Railway Alabama State Docks, and has a class-1 airport. Located in a lumbering region, its main activities are shipbuilding and fishing. The city was incorporated in 1946. It has a mayor and council form of government. Pop. (1950) 4,920.

CHICKASAW BAYOU or BLUFFS, Battle of, a Union defeat during Gen. U. S. Grant's ultimately successful campaign against Vicksburg, Miss., fought Dec. 29, 1862. On Dec. 8, 1862 Grant ordered Gen. W. T. Sherman to organize at Memphis, Tenn., an expedition which in cooperation with Adm. D. D. Porter's gunboat fleet should reduce Vicksburg. On the 22d the expedition rendezvoused at Friar's Point on the Mississippi, ready to move up the Yazoo River in rear of Vicksburg. Sherman had the four divisions of Gens. F. Steele, Geo. W. Morgan, M. L. Smith and A. J. Smith, aggregating about 30,000 men. The transports, preceded by the gunboats, entered Yazoo River on the 25th, and on the 26th and 27th the troops were landed on its south bank, confronting the bluffs overlooking the swamps through which ran Chickasaw Bayou. Gen. J. C. Pemberton, commanding the Confederate forces in Mississippi, was at Grenada opposing Grant, who was moving south from Grand Junction and Corinth on the line of the railroads. On the 21st Pemberton heard that the fleet and transports were moving down the Mississippi for the supposed purpose of attacking Vicksburg, which at the time was held by Gen. Martin L. Smith with the brigade of Gen. S. D. Lee. Vaughn's brigade was immediately ordered to Vicksburg, and was soon followed by the brigades of Gregg and S. M. Barton. Pemberton arrived at Vicksburg on the 26th and the last of the three brigades during the night of the 27th. Pemberton disposed his forces, under Vaughn, Gregg, Barton and Lee, on a line from Vicksburg on the left to Haynes' Bluff on the right, a distance of 13 miles, on high ground overlooking Chickasaw Bayou and the Yazoo River, S. D. Lee holding Walnut Hills from Vicksburg to Snyder's Mill on the right, a distance of 10 miles. Lee, a good engineer and a fine officer, strengthened his position by works for his batteries and rifle pits on the slope of the bluff, which rose about 200 feet above the bayou. Between this position and where Sherman had landed was bottom land, almost wholly densely wooded, intersected with bayous and low, swampy ground. There were but three roads through this area, and these were obstructed by earthworks and felled timber. By these Sherman advanced on the morning of the 27th, Steele on the left, Morgan on the right of Steele and M. L. Smith and A. J. Smith on the right of Morgan. There was heavy skirmishing on the 27th and 28th, the Confederate outposts were driven in, and on the night of the 28th the Union troops lay parallel to Chickasaw or Walnut Hills bluff and about 600 yards from its foot. The main assault on the bluff was to be made by Morgan, supported by Steele; while, to make a diversion in favor of Morgan, A. J. Smith, with M. L. Smith's division and one brigade of his own, was to cross a lake, a mile below Morgan, by a narrow sand bar, and attack. On the extreme right the rest of

A. J. Smith's division was to demonstrate on the road to Vicksburg. On the morning of the 29th Morgan represented to Sherman that an attack from his position was impracticable; but Sherman, after an examination, rode off to his headquarters, whence he sent his adjutant general to Morgan with this message: "Tell Morgan to give the signal for assault; that we will lose 5,000 men before we take Vicksburg, and may as well lose them here as anywhere else." Morgan replied that Sherman's entire army could not carry the position in his front, but that he would order the assault. De Courcy's brigade of Morgan's division, and the two brigades of Blair and Thayer of Steele's, were formed for the assault. The signal was given by a heavy artillery fire upon the Confederate lines, and at 12 o'clock the three brigades went forward. By some misunderstanding Thayer's brigade, with the exception of the 4th Iowa, diverged too far to the right, but De Courcy, Blair and Thayer (with the 4th Iowa), about 6,000 men, after clearing the obstruction in front and floundering through deep mire and tangled marsh, under a terrific fire of artillery, finally made a lodgment on the hard tableland at the foot of the bluff, where an abandoned line of works gave shelter, and where some of the men stopped. All formation was broken up, brigades and regiments mixed, but on went the main body, pushed up the bluff, and reached different points of Lee's works, where they were met on both flanks by such a withering fire from the rifle pits that ran diagonally up the slope of the hill, and so severe a cross-fire of shell and canister from the batteries, that the men faltered and, no support being in sight, fell back to the point of starting, leaving about 1,500 killed, wounded and captured. Lee lost 115. More to the right, where A. J. Smith was to demonstrate, the 6th Missouri gained the levee at the foot of the bluff, but not able to go farther under the hot fire poured upon them from above, the men sought shelter by digging with hands and bayonets into the bank of the levee, where they remained until night covered their withdrawal, after a loss of 57 killed and wounded. Sherman thought of renewing the assault in the morning, but after a personal examination, he came to the conclusion that the enemy's center could not be broken without crippling his army beyond the power to act with any vigor afterward, and proposed to attack Haynes' Bluff, higher up the Yazoo. Preparations were made to assault at 4 o'clock on the morning of Jan. 1, 1863. Admiral Porter, who was to cooperate in this attack, found the fog so dense on the river that he could not move his boats. The attack was deferred and then abandoned, and by sunrise, January 2, the troops were all embarked on transports and sailed for Milliken's Bend. The Union loss in the assault on Chickasaw Bluffs and in the skirmishing preceding it was 1,213 killed and wounded, and 563 missing. The Confederate loss was 177 killed and wounded, and 10 missing.

E. A. CARMAN.

CHICKASHA, chik'-a-shā, city, Oklahoma; seat of Grady County; situated at an altitude of 1,094 feet on the Washita River, a tributary of the Red River, 40 miles southwest of Oklahoma City. It is served by the Chicago, Rock Island and Pacific and the St. Louis-San Francisco railroads; Chickasha Airport (municipal) is three miles northwest. The surrounding country, in

the fertile Washita Valley, is predominantly agricultural, with cotton the chief crop, and corn, wheat, alfalfa, and sorghum extensively grown; there are also gas and oil wells. Cotton ginning and production of cottonseed oil are mainstays of the city's industries, with manufactures of flour and feeds, dairy products, farm machinery and oilfield equipment.

Chickasha has a Carnegie public library and is the seat of the Oklahoma College for Women (founded 1908). The city owns and operates its water supply system. Incorporated as a town in 1892, as a city in 1898, Chickasha has the council-manager form of government. Pop. (1950) 15,842.

CHICKEN. See POULTRY.

CHICKEN FLEA, STICKTIGHT FLEA, or **TROPICAL HEN FLEA**, the common name of *Echidnophaga gallinacea*, a pest of young chickens in tropical and subtropical regions, and destructive from Florida to Texas. It is smaller and shorter than the cat flea, with the eyes and antennae in the higher part of the head, and it does not hop. It abounds mostly in shady places, under old houses, and in earthen floors. It is first observed to infest young chickens and turkeys, and by its number and pertinacity kills young chickens, while being more or less permanently parasitic on hens. See also JIGGER; SARCOPSYLLA.

CHICKEN LICE, several species of bird lice (Mallophaga), or louse-like wingless insects, afflicting chickens and hens. Unlike the louse (*Pediculus*), which obtains its nourishment by suction, the bird lice have free jaws adapted for cutting feathers, though they also draw blood from the skin of their host. The large chicken louse (*Goniocotes abdominalis*) is less common than the lesser chicken louse (*G. hollisteri*); it is only one millimeter long, while the first-named kind is three millimeters long. Quite a different kind is the common hen louse (*Menopon pallidum*), which is the most abundant and annoying of all. It differs from the others in its light color and greater activity, running among the feathers and from them upon the hands of persons handling fowls. It is from one to one and a half millimeters long, rather slender and of a pale straw-yellow color. Fowls should be allowed plenty of ashes and road dust in which to roll. An infested henry should be well fumigated and whitewashed, and insect powder should be dusted upon the birds themselves.

CHICKEN MITE, or POULTRY MITE, a small mite (*Dermanyssus gallinae*) which gathers on fowls at night and sucks their blood. It is about one millimeter high, light gray, with dark patches, but red when gorged with blood. It swarms in cracks and corners of the henhouse and should not be confounded with the bird tick (*D. avium*).

CHICKEN POX or VARICELLA, vār-ī-sēl'-ā, an acute, highly contagious, viral disease having mild constitutional symptoms and accompanied by a papular and vesicular eruption appearing in successive crops. The disease was described clinically in 1553 by Giovanni Filippo Ingrassia (1510-1580), and again by William Heberden (1710-1801) about the middle of the 18th century. Heberden differentiated it from

smallpox, with which it had been confused. The elementary bodies found in the fluid from the vesicles, under the microscope, leave no doubt of its viral nature. Mouth lesions are especially likely to spread the disease.

Chicken pox is seen almost exclusively in children and except in infants almost never causes death. One attack usually confers immunity for the life of the subject. The incubation stage is about 14 days, the attack beginning with loss of appetite, mild fever, and within 24 hours the appearance of the eruption. The eruption is most abundant on the trunk and for several days new crops appear. Secondary infection from scratching is common. Most cases are diagnosed easily, but occasionally it is necessary to distinguish it from smallpox by specific tests for the smallpox virus. *Herpes zoster* may resemble chicken pox occasionally.

Treatment is symptomatic. In the very young, restraint may have to be imposed to prevent scratching and scarring.

HAROLD WELLINGTON JONES, M.D.

CHICKEN SNAKE, a name applied to the races of the pilot blacksnake (*Elaphe obsoleta*) that inhabit the Atlantic coastal plain and peninsular Florida in southeastern United States. The name is more often applied to the four-lined chicken snake (sometimes called the yellow rat snake, *Elaphe obsoleta quadrivittata*), long believed to be a distinct species, but now known to interbreed with the gray rat snake (*E. o. coninus*) of the Mississippi Valley, and with the pilot blacksnake to the north. Juveniles of the various races are all blotched or spotted and virtually indistinguishable, but the pattern in the adult chicken snake changes to one consisting of four prominent dark stripes that extend the entire length of the body, with a ground color that is yellow or olive. Chicken snakes occasionally invade poultry yards to devour eggs or prey upon hicks, but small rodents usually comprise the bulk of their fare, with song birds occasionally falling victim. The rat or chicken snakes climb rees or shrubs, possibly in search of bird nests. They are all nonvenomous, and kill their prey by constriction or squeezing.

CHICKEN TICK. The chicken or fowl tick (*Aryas persicus* or *miniatus*) is a first-magnitude pest of domestic fowls and many wild birds in warm areas throughout the world. In the United States its depredations on chickens and turkeys—much less frequently on ducks and geese—cause heavy loss to poultry raisers in the extreme South, and especially in the arid Southwest. The reddish or brown tick has a flattened, obovate body, and the larger female attains a length of nearly one third of an inch when adult. These active parasites hide during the day in dark recesses in or near the henhouses, or cluster under loose bark even at a considerable distance from them. They come out at night, in a fashion similar to bedbugs, to gorge themselves on the blood of the roosting birds, which may be weakened or even killed. They also cause a form of paralysis and are vectors of a very fatal germ disease, fowl spirochaetosis. Control consists of eradication of infestation in the henhouses and the use of creosote and other chemicals to repel or kill the ticks.

CHICKERING. Jonas, American piano

maker: b. Mason Village, N. H., April 5, 1798; d. Boston, Mass., Dec. 8, 1853. He was apprenticed to a cabinetmaker as a boy, and in 1823 began to make pianos in Boston in partnership with James Stewart. The enterprise expanded with the formation of a second partnership (1830-1841) with John Mackay; at Chickering's death his large factory in Boston was turning out 2,000 pianos a year. Among Chickering's improvements was the perfection of the iron frame cast in a single piece (1837).

CHICKWEED, several plants in the family Caryophyllaceae, eaten by birds. Common chickweed, *Stellaria media*, a native of Eurasia, now hugs the heels of man everywhere in temperate waste places.

CHICLANA DE LA FRONTERA, chē-klā'nā thā lā frōn-tā'rā, commune, Spain; in Cádiz Province, 12 miles southeast of Cádiz. It is the center of a vine-growing and pine forest region, and produces chiefly wine and lumber. Chiclana is well built, with many houses of snow-white hewn stone enclosed by gardens. The thermal baths are much frequented. Pop. (1940) 17,047.

CHICLAYO, chē-klā'yō, city, Peru; capital of Lambayeque Department; situated near the Pacific coast, some 400 miles north-northwest of Lima. It is in an agricultural region producing sugar, rice, and cotton, and its chief industries are cotton ginning, and the processing and packing of foodstuffs. Chiclayo is connected by railroad with the ports of Pimental and Eten. Pop. (1940) 32,646.

CHICLE, chik'l, the main ingredient of chewing gum, the coagulated milky latex obtained by tapping the bark of the sapodilla (*Achras sapota*; also called naseberry or chicozapote). The chief sources are the Yucatán Peninsula, and the Mexican states of Chiapas and Tabasco, where the sapodilla grows wild. The latex is boiled and formed into blocks for export, mainly to the United States, where it is refined.

CHICO, chē'kō, city, California; in Butte County; altitude 193 feet. It is situated on the Sacramento River, 80 miles north of Sacramento, is served by the Southern Pacific Company, and has a municipal airport. The county produces almonds, rice, sugar beets, and fruits. The city does fruit and food processing and packing, manufactures beet sugar, and has railroad shops and lumber and cement works. It is the seat of Chico State College, coeducational, founded in 1889. Chico was settled in 1847 and incorporated as a city in 1923. It has a city manager-council government. Pop. (1940) 9,287; (1950) 12,272.

CHICOPEE, chik'ū-pē, city, Massachusetts; in Hampden County. It is situated at an altitude of 92 feet on the east bank of the Connecticut River at the mouth of the Chicopee, 3 miles north of Springfield, and is served by the Boston and Maine Railroad. Formerly a town, the city includes five separate units: Chicopee, Chicopee Falls, Willimansett, Fairview, and Aldenville. It manufactures cotton and knit goods, sporting goods, tires, paper products, firearms, textile machinery, furniture and fixtures and radio parts. Westover Field, an army airbase, is here. Bog iron mining, foundries, friction matches, swords, bronze statuary and doors were important in

Chicopee's early industry. Settled in 1652, it separated from Springfield in 1848 and became a city in 1890. Pop. (1940) 41,664; (1950) 49,211.

CHICOPEE, river, Massachusetts, which rises in Hampden County and flows west into the Connecticut River just above Springfield, Mass. It is formed by the junction of the Swift and Quaboag rivers at the village of Three Rivers 16 miles east-northeast of Springfield. It is an important source of power for towns along its course.

CHICORY, *chik'ò-rí*, or **SUCCORY**, a perennial herb (*Chicorium intybus*) of the family *Chicoriaceae*, native to Europe but carried to many parts of the world as a minor garden and field crop; sometimes escaping from cultivation to become a weed. Its perennial roots store inulin and send up branched stems three to six feet tall with leaves similar to those of the related dandelion, but with numerous showy blue flowers. Leaves of certain varieties are used in salads (Witloof salad and *barbe de capucin* of Continental Europe) and for greens. Chicory roots, from spring-planted seed, are dried, roasted, ground, and used as an adjunct to coffee, the presence of chicory giving the brew deeper color, more lasting flavor and aroma. A cool, humid growing season makes for quality. The endive (*Chicorium endivia*) is a close relation. Most of the United States crop is grown in Michigan.

H. C. RATHER,

Head, Farm Crops Department, Michigan State College.

CHICOUTIMI, *shì-kōò'ti-mì*, town, Province of Quebec, Canada, county seat of Chicoutimi County, on the Saguenay River, 277 miles by Canadian National Railways from the city of Quebec. Its industries include lumber, planing and grist mills, flooring, sash and door, furniture factories, and machine shops. Chicoutimi is an important hunting, fishing, and general tourist center, being the steamship terminus of the picturesque Saguenay River route. It is the seat of a Roman Catholic bishopric and has a seminary, a normal school, and a hospital. Population (1951) 23,216.

CHIDAMBARAM, *chì-dũm'bá-rám*, town, India, in South Arcot District, southeast Madras Province, 23 miles south-southwest of Cuddalore and 125 miles south-southwest of the city of Madras. Rice and peanuts are processed here. Of numerous temples and pagodas, some of which date back to the 10th century, a temple to Siva is most important, drawing thousands of pilgrims to the town annually. Pop. (1941) 26,212.

CHIEF JUSTICE, the title of the presiding justice of the Supreme Court of the United States, and of the presiding justice of the several state supreme courts. Various other courts in the United States are also presided over by a chief justice. The chief justice of the United States is the highest judicial officer of the republic. Among his functions are those of administering the oath of office to the president and vice president at their inauguration, and of presiding over the Senate when that body is resolved into a high court for the trial of impeachments. In official dignity, he ranks next after the president.

Chief justices of the United States have been:

John Jay, of New York, nominated by George Washington, Sept. 26, 1789; resigned 1795.

John Rutledge, of South Carolina, nominated by George Washington, 1795; presided summer term, rejected by Senate, December 1795.

Oliver Ellsworth, of Connecticut, nominated by George Washington, 1796; confirmed March 4, 1796; resigned 1799.

John Marshall, of Virginia, nominated by John Adams, Jan. 20, 1801; confirmed Jan. 27, 1801; died July 6, 1835.

Roger Brooke Taney, of Maryland, nominated by Andrew Jackson, Dec. 28, 1835; confirmed March 15, 1836; died Oct. 12, 1864.

Salmon Portland Chase, of Ohio, nominated by Abraham Lincoln, Dec. 6, 1864; confirmed immediately; died May 7, 1873.

Morrison Remick Waite, of Ohio, nominated by Ulysses S. Grant, Jan. 19, 1874; confirmed Jan. 21, 1874; died March 23, 1888.

Melville Weston Fuller, of Illinois, nominated by Grover Cleveland, April 30, 1888; confirmed July 20, 1888; died July 4, 1910.

Edward Douglass White, of Louisiana, nominated by William Howard Taft, Dec. 10, 1910; confirmed Dec. 12, 1910; died May 19, 1921.

William Howard Taft, of Connecticut, nominated by Warren G. Harding, June 30, 1921; confirmed the same day; resigned Feb. 3, 1930.

Charles Evans Hughes, of New York, nominated by Herbert C. Hoover, Feb. 3, 1930; confirmed Feb. 14, 1930; resigned July 1, 1941.

Harlan Fiske Stone, of New York, nominated by Franklin D. Roosevelt, June 12, 1941; confirmed June 27, 1941; died April 22, 1946.

Frederick Moore Vinson, of Kentucky, nominated by Harry S. Truman, June 6, 1946; confirmed June 20, 1946; died Sept. 8, 1953.

Earl Warren, of California, nominated by Dwight D. Eisenhower, Sept. 30, 1953; presided at session opening Oct. 5, 1953; confirmed March 1, 1954.

CHIEM, Lake, *kēm* (Ger. *CHIEMSEE*, *kēm'-zā*), the largest lake in Bavaria, Germany. It lies about 40 miles east-southeast of Munich and about 30 miles west of Salzburg, Austria, covers an area of 32 square miles, and is 1,600 feet above sea level. It is drained by the Alz, a tributary of the Inn River. There are three islands in the lake: Herreninsel, containing a castle; Fraueninsel, the largest, containing a cloister and a fishing village; and Krautinsel.

CH'ÏEN LUNG, *chê-ên' lōōng'* or **KIEN LUNG** (dynastic name *KAO TSUNG*), Chinese emperor: b. Peking, Sept. 25, 1711; d. there Feb. 7, 1799. He was the fourth emperor of the Ch'ing (Manchu) dynasty, succeeding his father, Yung Chêng, in 1736, and reigning until 1796, when he abdicated in favor of his son, Chia Ch'ing. Under him China reached its greatest territorial limits, control over Tibet being established in 1751 and subjugation of the western areas which later became Sinkiang Province being accomplished between 1755 and 1760. Ch'ien Lung successfully resisted the efforts of European powers to expand relations with China, but in 1784 he allowed the United States to join other countries already trading at Canton.

His interest in literature was partly motivated by a desire to have unfavorable references to the Manchus expunged from all Chinese works. He authorized the compilation of three great collections of literature: a collection of histories (1739-1746); the Imperial Manuscript Library, a catalogue with critical comments on 3,462 works (1772-1781); and a 92-volume catalogue discussing 6,734 works not included in the library (1789).

CHIERI, *kyà'rè*, commune, Italy, in Torino Province, Piedmont Region, eight miles southeast of Turin. It is a textile manufacturing city. The largest Gothic church in Piedmont is here, and

the old walls still stand around the city. In the 11th century it was an independent republic. Pop. (1951) 14,788.

CHIETI, kyá'tè, (ancient TEATE) ; commune, Italy, capital of province of same name, on a hill near the right bank of the Pescara River, 93 miles east-northeast of Rome. It was anciently one of the largest and most important towns in this part of Italy, and was for some centuries in possession of the Greeks, from whom it passed successively to the Romans, Lombards, Franks, and Normans. In 1802 it was taken by the French troops. The modern town is the see of an archbishop and the seat of a superior civil and criminal court, and has manufactures of woolens, textiles, and a trade in silk, wine, wheat, and oil. Pop. (1951) 40,688.

CHIFFCHAFF, chíf'cháf, a small European bird (*Sylvia hippolaïs* or *Phylloscopus collybita*), of the warbler family (Sylviidae), so named from its cry. Its head, back and upper wings are ashy brown, and its under parts are brownish green dashed with yellow. In length it is between four and five inches, and it frequents woods, hedges and thickets. Its food consists of the larvae of various insects and some of the smaller moths.

CHIFLEY, Joseph Benedict, Australian political leader: b. Bathurst, New South Wales, Sept. 22, 1885; d. Canberra, June 13, 1951. After being educated at Patrician Brothers High School in Bathurst, he obtained employment with the New South Wales government railways, for which he became a locomotive engineer. Becoming an active member of the Federation of Locomotive Enginemen's Union, he became interested in labor politics and privately took up the study of economics, finance, and industrial law, eventually representing his union and the Locomen's Association before the nation's industrial arbitration courts. In 1928 he was elected a Labour Party member of the federal House of Representatives from the Macquarie constituency of New South Wales, and the following year he was appointed to serve as minister of defense in the Labour Cabinet. Although he lost his parliamentary seat in the general election of 1931, he was called on by non-labour administrations to serve in 1935-1936 on the Royal Commission on Monetary and Banking Systems, in 1939 on the Capital Issues Advisory Board, and in 1940 as director of labor supply and regulation for New South Wales.

In the 1940 general election Macquarie returned him to the House of Representatives, and in October 1941 Labour Prime Minister John Curtin (q.v.) appointed him commonwealth treasurer. During the succeeding war years, Chifley introduced a comprehensive system of wartime financial controls, planning and carrying through the greatest war loans in Australia's history, as well as tax increases, to meet wartime financial demands. From 1942 to 1945 he additionally assumed the new post of minister for post-war reconstruction, which he retained until February 1945. During the illness of John Curtin he was acting prime minister from April 30, 1945, and on July 4, following Curtin's death, he assumed the premiership, at the same time retaining his treasury post. At the general election of September 1946, when the Labour Party was again returned to power, Chifley continued as

prime minister. In the 1949 elections, however, his government was defeated when the Liberal Party successfully campaigned on the issue of a return to the free enterprise system and an end to socialism, and formed a coalition government under Robert G. Menzies. Chifley again led his party in the elections of April 1951, but was defeated for a second time by the Menzies' coalition.

CHIGGER. See JIGGER; SARCOPSYLLA.

CHIGI, ké'jè, a noble Italian family, founded by AGOSTINO CHIGI (1465?-1520) of Siena. He became a patron of the fine arts and banker for the pope. Peruzzi built for him the well-known Villa Farnese. Raphael painted there the *Triumph of Galatea* and *The Legend of Psyche*. Sodoma ornamented it with his fresco *The History of Alexander and Roxanna*. Consult Cugnino's *Agostino Chigi il Magnifico*. The family was further distinguished by five cardinals and one pope, Fabio Chigi (1599-1667), afterward Alexander VII (q.v.). FLAVIO CHIGI: (1810-1885), was one of the papal guard until 1848, when he was made bishop of Mira in *partibus*, nuncio at Munich, but was sent to Paris (1873) and later in the same year was made cardinal.

CHIGNECTO BAY, shíg-nék'tò, Canada, an inlet at the head of the Bay of Fundy, separating Nova Scotia from New Brunswick. It is 30 miles long and 8 broad, and has an isthmus of only 12 miles in width between it and Northumberland Strait, in the Gulf of Saint Lawrence. In 1888 work was begun on the construction of a ship railway across the neck of land connecting Nova Scotia with the mainland of Canada. The railway, 18 miles long, by uniting the Gulf of Saint Lawrence with the Bay of Fundy and the waters of the Atlantic Ocean, saves a run of several hundred miles around the province. The bay is noted for its high tides (to 50 feet).

CHIGNON, shên-yôn, (Fr. *chignon*, the nape of the neck), a peculiar arrangement of the hair, worn by women, a knot or mass, natural or artificial, arranged low on the back of the head, at the nape of the neck. This style of hairdressing was common in the 18th century, but fell into disuse. It was revived in the last half of the 19th century, again discontinued, and again revived in 1931, 1945, and 1951.

CHIGO, ché'gò. See JIGGER; SARCOPSYLLA.

CHIHUAHUA, ché-wā'wā, largest state of the Mexican Republic, bounded on the north by the United States (New Mexico and Texas). The northeastern section comprises a rolling, arid plain of great extent, which rises gradually from the Rio Grande (or Bravo) toward the foothills of the Sierra Madre Occidental which traverses the southwestern section of the state from northwest to southeast. Near the Coahuila border, in the southeast, is the Bolsón de Mapimí, a remarkable arid depression which, with irrigation, has great agricultural possibilities. Rainfall is limited throughout the state, except during the months from July to September, and agriculture is generally successful only where land can be irrigated. Because of this, cattle raising and mining are the principal activities, and population is sparse. A large lake (To-

ronto) has been created for irrigation purposes by damming the Conchos southwest of Camargo. Cotton, wheat, corn, and fruits of the temperate zone are grown to some degree. One of the principal agricultural products is a cheese which is known all over Mexico. The mountain areas of the southwest, in which most of the mineral wealth is located, are also rich in cedar and birch, and support an active lumbering industry, including the extraction of resin and turpentine. Several rivers have their headwaters in this section; some, like the Conchos, flowing east and north to the Río Grande, others, like those of the Yaquí and Fuerte systems, flowing west to the Gulf of California. Silver has been mined in Chihuahua on an extensive scale since 1544, some of the oldest and most productive silver mines in Mexico, notably the Parral (Parral Hidalgo) and the Santa Bárbara in the south, being in the state. Other minerals which are mined include lead, zinc, copper, mercury, gold, and coal.

Historically, the state is noted for its loyalty to Benito Pablo Juárez, president from 1861-1867, and for its savage fighters during the internal struggles after 1910. Following a raid on Columbus, New Mexico, by followers of Francisco Villa in 1916, the state was invaded by United States troops under Gen. John Pershing in an unsuccessful attempt to capture Villa. The state is well served by railways and roads, the principal ones running from the border cities of El Paso, Texas, and Ciudad Juárez to the capital city of Chihuahua in the center of the state, and south to Durango. There is also a railway which turns west from Ciudad Juárez to rejoin the main line at the capital, and a rail and road link with Ojinaga, another border town. The land area of the state is 94,822 square miles; pop. (1940) 613,696.

CHIHUAHUA, Mexico, capital of the State of Chihuahua, located at an altitude of some 4,600 feet in a rich livestock and mining district on the main highway and railroad line running between Mexico City and El Paso, Texas. Although the city contains many fine colonial buildings, it is essentially modern and international in character, having closer material links with the United States than with the more southerly parts of Mexico. The climate is warm in mid-summer, but moderate during the rest of the year. The town is built on the site of an Indian town which was conquered by the Spaniards, and was founded by Diego de Ibarra in 1539. Further development was retarded until silver mining in the vicinity rose to unprecedented heights early in the 18th century. The fine colonial buildings of the town, notably the profusely ornamented cathedral (built 1717-1789), date from this period. In 1811, Miguel Hidalgo y Costilla, the pioneer of Mexican independence from Spain, after a series of disastrous defeats which had followed an initial period of success during which he nearly reached the gates of Mexico City, was retreating northward when he was captured and taken to Chihuahua. He was here imprisoned and later shot by agents of the Spanish royal government. There is a fine monument to him in the Jardín Hidalgo. For a brief period in 1864, Chihuahua was the provisional capital of the Benito Pablo Juárez government during its struggle against Maximilian and the French intervention. The prin-

cipal industrial establishments are smelters and foundries, flour and cottonseed mills, soap factories, and breweries. Pop. (1940) 56,805.

CHILAN BALAM, chē-lān' bā-lām', *The Books of*, a series of writings in the Maya language, set down in the modified Latin alphabet introduced by the Spanish conquerors of Yucatán, probably soon after the conquest. Certain portions, however, date from as late as the early 17th century. *Chilan*, according to Diego de Landa, bishop of Yucatán from 1572 to 1579, was a term for a Maya priest whose functions were also those of medicine man and prophet, while *balam* means *tiger*, a symbol of this priestly caste. The various books making up the series are named for the village in which each was composed, and apparently are in part copies of older, hieroglyphic manuscripts which were secretly preserved from the general destruction of native writings which accompanied the conquest, and in part the rendering of stories and lore preserved orally, but they nevertheless contain many obvious interpolations of the Christian tradition absorbed by the scribes. Their contents are (1) prophecy and astrology, both showing evidence of European influence, and in a few cases clearly Christian teachings; (2) medical practice (diagnosis and preparation of remedies), showing European influence in some instances; and (3) a history of events from the settlement of Mayapán (1st century A.D.?) to the conquest. The history, unfortunately, is joined to a chronology which seldom gives the actual dates of happenings, but rather dates arbitrarily assigned for magical reasons. The books were first published in the United States by Daniel Garrison Brinton as *The Maya Chronicles* (Philadelphia 1882).

CHILBLAIN, chil'blān, or **FROSTBITE**, a mild or severe inflammatory reaction from the effects of severe cold on the toes, fingers, nose, chin, or ears. In mild cases there is swelling only, with an inflammation of the skin. This disappears and the part is apt to be tender. In severe frostbite there is ulceration and sloughing of the part. The treatment of mild chilblain is by slow raising of the temperature of the chilled part to that of the body. Too rapid heating results disastrously.

CHILCOTT, chil'kōt, **Ellery Channing**, American agriculturist: b. East Hamburg, N. Y., April 8, 1859. d. Ann Arbor, Mich., Nov. 14, 1930. He was educated in the common schools and at the Friends' Institute of East Hamburg. From 1882 to 1892 he was owner and manager of a stock ranch in Campbell County, S. D., and at the same time acted as United States deputy surveyor. He was elected to the state Senate in 1892, was professor of agriculture 1892-1897, professor of geology and agronomy and vice director 1897-1905 of the South Dakota Agricultural College. From 1893 to 1905 he was agriculturist of the United States Experiment Station, South Dakota. He wrote *The Relations between Precipitation and Crop Yields in the Great Pl.* (1927).

CHILD, Francis James, American scholar and educator: b. Boston, Mass., Feb. 1, 1825; d. Cambridge, Sept. 11, 1896. He was Boylston professor of rhetoric and oratory at Harvard from 1851 until 1876, when he exchanged for th

chair of English literature, which he held until his death. Child was an authority on Geoffrey Chaucer and John Gower. His principal work was the monumental *English and Scottish Popular Ballads* (5 vols., 1883-1898), an enlargement of his *English and Scottish Ballads* (8 vols., 1857-1858). He also edited *Four Old Plays—Three Interludes: Thersytes, Jack Jugler, and Heywood's Pardoner and Frere: and Jocasta, a Tragedy by Gascoigne and Kinwelmarsh* (1848); and *Poetical Works of Edmund Spenser* (1855).

CHILD, Sir Josiah, English merchant and economist: b. London, 1630; d. June 22, 1699. He acquired a large fortune in Portsmouth as supplier to the navy and invested much of it in the East India Company. He served as director of the company from 1677 and was its governor from 1681 to 1683 and from 1686 to 1688. Child wrote several papers in defense of trade with the East, arguing, in opposition to those who deplored the drain of gold, that the India trade passed through other countries with which Britain traded and thus returned indirectly a surplus in cash. He is best known for his *Brief Observations Concerning Trade and the Interest of Money* (1668), of which an enlarged edition was published in 1690, entitled *A New Discourse on Trade*. It was written in defense of the reduction, by legal enactment, of the rate of interest from 8 to 6 per cent, and recommended a further reduction, to 4 per cent. It also advocated the compulsory emigration of paupers to the colonies. Child served in Parliament in 1659, 1673-1678, and 1685-1687. He became a baronet in 1678.

CHILD, Lydia Maria (nee FRANCIS), American abolitionist and author: b. Medford, Mass., Feb. 11, 1802; d. Wayland, Mass. Oct. 20, 1880. Her first novel, *Hobomok*, was published in 1824, and from then until her death she continued her literary activity. From 1826 to 1834 she edited the *Juvenile Miscellany*, the first children's periodical of literary merit published in the United States. In 1828 she married David Lee Child, a Boston lawyer. The Childs became ardent abolitionists, and Mrs. Child published one of the first antislavery books, *An Appeal in Favor of That Class of Americans Called Africans* (1833), which aroused much opposition and cost her her literary popularity in the South. From 1841 to 1849 she edited the *National Anti-Slavery Standard*, her husband serving as coeditor in 1843-1844. Her numerous works include *The First Settlers of New England* (1829); *Philothea* (1836); *Fact and Fiction* (1846); *Isaac T. Hopper* (1853); *Progress of Religious Ideas Through Successive Ages* (3 vols., 1855); and *A Romance of the Republic* (1867).

CHILD LABOR. The term "child labor" is defined by the United States Department of Labor as the employment of boys and girls when they are too young to work for hire, or when they are employed at jobs unsuitable or unsafe for children of their ages or under conditions injurious to their welfare. It is any employment that robs children of their rightful heritage of chance for healthful development, full educational opportunities, and necessary playtime. The term has had different meanings at various times and in various communities, depending on society's concept of its responsibility for its

youth. This concept has steadily broadened in scope as knowledge of the needs of children and young people has expanded, as awareness of the necessity for an educated citizenry in a democracy has increased, and as labor standards in general have risen to higher levels.

Legal Regulation.—The movement for legal regulation of child labor began in England at the end of the 18th century, when the introduction of the factory system led to the exploitation of young children. In the United States initial efforts to control child labor were designed to combat conditions that a few decades later would seem almost incredible. At the beginning of the 20th century children 8 and 10 years of age still tended cotton looms, and boys only a little older stood all night before the glory holes of glass factories and worked as breaker and mule boys in coal mines. By the 1950's the worst abuses of child labor in the United States had been curbed by state and federal legislation and by an enlightened public opinion. The modern attitude in respect to child labor was foreshadowed by the Children's Charter of the White House Conference on Child Health and Protection (1930), which stated:

"For every child protection against labor that stunts growth, either physical or mental, that limits education, that deprives children of the right of comradeship, of play, and of joy. . . ."

More specifically, the Midcentury White House Conference on Children and Youth (1950) adopted the following recommendation:

"That states and other appropriate public bodies establish and enforce standards covering the employment of youth in all occupations, such standards to include minimum age and wages, as well as hours of work, night work, protection from hazardous occupations, and provisions for workmen's compensation. . . ."

Federal Legislation.—One great step forward in achieving these standards was taken through the child labor provisions of the Fair Labor Standards Act of 1938 and its 1949 amendments (effective Jan. 25, 1950), which prohibit (1) the shipment in interstate or foreign commerce of goods produced in establishments where oppressive child labor has been employed within 30 days prior to removal of the goods; and (2) the employment of oppressive child labor in interstate or foreign commerce or in the production of goods for such commerce. Oppressive child labor is defined as employment of minors under 16 years of age in any occupation covered by the act and employment of minors between 16 and 18 in occupations declared hazardous by the secretary of labor. Children between 14 and 16 may be employed outside of school hours in a limited number of occupations under regulations issued by the secretary of labor, where such employment has been determined not to interfere with their schooling or health and well-being. Exempted from these provisions are children employed by their parents in occupations other than manufacturing or mining and other occupations designated as hazardous. Also exempted are children employed in agriculture outside of school hours, and those employed as actors in theatrical, motion picture, radio, and television productions, and in the delivery of newspapers to consumers. As of 1952, work in the following occupations had been declared hazardous and thus closed to minors under 18: (1) explosives manufacturing; (2) motor vehicle driving and helping; (3) coal

mining; (4) logging and sawmilling, with specified exceptions; (5) working with power-driven woodworking machines; (6) work involving exposure to radioactive substances; (7) working with power-driven hoisting apparatus, including elevators; (8) working with specified power-driven metalworking machines; (9) mining other than coal mining, with specified exceptions; and (10) slaughtering and meat packing or rendering.

Two other federal laws contain child labor provisions. The Public Contracts (Walsh-Healey) Act of 1936 requires that any contractor manufacturing or furnishing goods or supplies for the federal government in an amount exceeding \$10,000 will not employ boys under 16 or girls under 18 on such work. The Sugar Act of 1948, which succeeded the 1937 act, stipulates that to qualify for benefit payments growers of sugar beets and sugarcane must not employ children under 14, or children 14 to 16 for more than 8 hours a day.

Prior to the enactment of these laws, three unsuccessful attempts had been made to control child labor by federal legislation. The Child Labor Act of 1916, the result of 10 years of effort, forbade the shipment in interstate and foreign commerce of goods produced in specified industries where children were employed in violation of specified age and hour standards. This law became effective on Sept. 1, 1917. Nine months later, on June 3, 1918, it was declared unconstitutional on the ground that Congress had exceeded its constitutional power to regulate interstate commerce (*Hammer v. Dagenhart*). The second attempt, the child labor clauses of the Revenue Act of 1919, provided for the levying of a tax of 10 per cent on the net profits of specified industries employing child labor. This act, which became effective in April 1919, was declared unconstitutional on May 15, 1922, on the ground that Congress, under the guise of a tax which on the face of the act was a penalty, could not regulate a matter within the reserved rights of the states (*Bailey v. Drexel Furniture Co.*). Control of child labor through the codes of fair competition established under the National Industrial Recovery Act of 1933 was likewise short-lived. Almost all the codes contained a basic 16-year minimum age provision for all employment, and about three fourths of them set a minimum age of 18 for occupations especially hazardous or detrimental to health. The entire act was declared unconstitutional on May 27, 1935, on the ground that it attempted to regulate intrastate transactions outside the authority of Congress and was an unconstitutional delegation of legislative power (*Schechter Poultry Corp. v. United States*), but industry's acceptance of the 16-year minimum age standard undoubtedly prepared the ground for public support of this standard in the Fair Labor Standards Act of 1938.

The decisions that the child labor laws of 1916 and 1919 were unconstitutional showed the need for a constitutional amendment definitely giving Congress the power to enact child labor legislation, and led to strong agitation for such action. In June 1924, the 68th Congress adopted a joint resolution for an amendment giving it the power to limit, regulate, and prohibit the labor of persons under 18, and stipulating that the power of the states should not be impaired. Efforts to secure ratification of the amendment

by the required three fourths of the states arouse much opposition, and by 1937 only 28 states had ratified it. Endeavors to obtain the remaining 8 ratifications needed for adoption lapsed after February 1941, when the Supreme Court held that all the restrictions of the Fair Labor Standards Act, including those on child labor, were constitutional (*United States v. Darby Lumber Co.*). The court specifically overruled the decision which had declared the first federal child labor law unconstitutional. The 1941 decision settled the issue of constitutionality and removed the immediate necessity for ratifications of the amendment.

State Legislation.—Child labor is regulated by state governments as well as by the federal government. The first state law establishing a minimum age was enacted by Pennsylvania in 1848. It prohibited the employment of children under 12 years of age in textile mills. Child labor laws were also in effect in a number of other states many years before the enactment of federal legislation.

An employer must obey both state and federal laws affecting child labor; if they differ, he must follow the higher standard. State laws vary considerably as to occupations covered and standards set up for the employment of children and young people. Some laws apply to all gainful occupations, others exempt agriculture or domestic service, and still others apply only to specified establishments. Standards for state child labor laws recommended by the National Conference on Labor Legislation include:

(1) *Minimum age:* 16 for factory employment and any employment during school hours; 14 for nonfactory employment outside of school hours.

(2) *Hazardous occupations:* minimum age of 18 in a considerable number of hazardous occupations; state administrative agency authorized to determine such occupations.

(3) *Maximum daily and weekly hours:* 8-hour day and 40-hour week for minors under 18.

(4) *Night work during specified hours:* 12 hours of night work prohibited for minors between 16 and 18.

(5) *Employment certificates:* required for all minors under 18.

Although there has been steady progress in meeting these standards, none of them is met by all the states. As of 1951, the laws of 23 states, Alaska, and Puerto Rico set a basic minimum age of 16 for general employment; in 2 states, the age was 15; in 22 states, the District of Columbia, and Hawaii, 14. One state, while not setting a minimum age, did not permit employment of children required to attend school. For children under 16, the 8-hour day had been adopted in all but 5 states, and night work was prohibited for 12 hours or more in more than half the states. For minors 16 and 17 years of age, 15 states had set an 8-hour day, and 7 others had this standard for girls only. The 40-hour week was the standard in 5 states, Alaska, and Puerto Rico for those 16 and 17 years old. Most of the other states set a maximum 48-hour week for this age group. Employment or age certificates were required in 43 states, the District of Columbia, Alaska, Puerto Rico, and Hawaii for children under 16; and in 22 states, the District of Columbia, Puerto Rico, and Hawaii for minors 16 and 17 years of age. In the remaining states certificates were issued upon request.

Child Labor in Emergency Periods.—In the 1940's, when defense and war production created manpower shortages, there was a trend toward relaxing state child labor laws to meet the strong demand for young workers. Offsetting this trend was the policy of upholding child labor standards, adhered to by federal agencies, including

those concerned with manpower requirements, and by organized labor. Also effective was the work of woman's groups and other private organizations in defeating many bills designed to lower these standards. In 1942, the Children's Bureau organized the National Commission on Children in Wartime, which adopted the Chil-

dren's Charter in Wartime, emphasizing the danger of relaxing child labor standards. Nevertheless, employment (full and part time) of children 14 through 17 years of age increased from 875,000 to more than 3,000,000 during World War II. Thousands of young people dropped out of school; other thousands attended school and worked a 6- to 8-hour shift after school hours. The worst abuses during the war resulted not from relaxation of legal regulations but from low standards and exemptions in state laws, and from the inability of enforcement agencies to cope with illegal employment.

The national emergency and increased industrial production after the outbreak of the Korean War in 1950 created a situation similar to that during World War II, emphasizing the need for strengthening state laws and enforcement machinery. According to the United States Bureau of the Census, the number of employed minors (in both full- and part-time employment) in the age group from 14 to 17 increased from 2,071,000 in October 1949 to 2,469,000 in October 1950, but decreased to 2,344,000 by the same month in 1951 because of the decline in the employment of those 14 and 15 years of age. The totals are broken down as follows:

	Age group 14-15	Age group 16-17
October 1949	701,000	1,370,000
October 1950	916,000	1,553,000
October 1951	762,000	1,582,000

Although the Bureau of the Census does not customarily enumerate the number of employed children under 14 years of age, it made two sample surveys for the Department of Labor in 1950. These revealed a large number of children 10 through 13 years of age at work in agriculture, as newspaper carriers and sellers, as baby sitters, and in stores. In August 1950, an estimated 1,094,000 children (one eighth of the total population in this age group) were at work; in October, a school month, 719,000 (one twelfth of the total age group) were at work.

International Movements for Regulation.—

The International Association for Labour Legislation, established in 1900 with headquarters in Basel, Switzerland, was the first organization to focus attention on the international aspects of labor legislation, including that on child labor. A conference held at Bern, Switzerland, in 1913 recommended prohibition of night work for children under 16, but it took no action on minimum age in general. Largely as a result of the pioneering work of the association, the International Labour Organization (ILO) was established in Geneva in 1919 by the Treaty of Versailles. First an independent agency and later an autonomous associate of the League of Nations, the ILO is now a specialized agency of the United Nations. Article 41 of its constitution states that one of its guiding principles is "the abolition of child labour and the imposition of such limitations on the labour of young persons as shall permit the continuation of their education and assure their proper physical development."

The general conference of the ILO meets yearly and adopts draft conventions which are submitted to the member nations for ratification. The first conference, held in Washington, D.C., in 1919, adopted draft conventions setting a minimum age of 14 for employment in industry (with exceptions for Japan and India) and a minimum age of 18 for night work between 10 P.M. and 5 A.M. (with some exceptions). The second con-

ference, held in Genoa, Italy, in 1920, adopted a draft convention setting a minimum age of 14 for employment at sea. Conventions adopted in later years raised the standards and widened the scope of recommended child labor legislation. As of 1951, they provided for a 15-year minimum age in industrial and nonindustrial employment and on the high seas, with a higher age for trimmers and stokers on vessels, and a 14-year minimum age in agriculture. In addition, they prohibited a 12-hour period of night work for minors under 18 in both industrial and nonindustrial employment.

The 1945 conference of the ILO, held in Paris, France, adopted resolutions setting forth a full program for the protection of children and young workers. It held that governments "... should accept responsibility for assuring the health, welfare, and education of all children and young persons and the protection of all youthful workers of either sex, regardless of race, creed, colour, or family circumstances, both by national action and by appropriate measures of international cooperation," and that "... questions relating to the health, education, employment, protection and general welfare of children and young persons are interrelated and cannot be solved in isolation."

CHILD PSYCHOLOGY. Psychology by simple definition is the science of the mind. Mind is a comprehensive term which includes not only intelligence and thinking, but also sensations, perceptions, feelings, concepts, attitudes, and actions. Psychology as a science attempts to describe and to interpret the operations of the mind as made evident in observable behavior and recordable reactions. Child psychology is particularly concerned with the early organization of human personality—with the beginnings, the trends, and the patterns of mental development prior to the teens. The psychology of adolescent and adult is naturally continuous with that of the child.

The Cycle of Child Development.—What are the beginnings of the human mind? Birth marks the arrival but not the true commencement of an individual. The life career of the individual begins with conception, when the genes of father and mother unite and initiate a cycle of growth. A minute globule of protoplasm becomes an embryo, the embryo becomes a fetus, the fetus an infant, the infant a child, the child a youth, the youth an adult, the adult a parent. With parenthood another cycle of growth is liberated.

The genes initiate the mental as well as the physical products of growth. From the earliest

his body, "of growth. Growth, therefore, is the key concept for understanding the nature and the needs of the child mind.

The mind does not have a fixed separate existence within a bodily dwelling. It is part and parcel of an indivisible growing organism, responsive to the joint influence of the genes and of the environment. The mind cannot be regarded as pure energy, for it is a patterned and a patterning system. Indeed, the mind of the child is a living, growing action system. Our task in this brief article will be to trace the growth of that action system in the first ten years of life.

It takes a long time for a child to grow up. Physical maturity (and, in large measure, also psychological maturity) is reached at about the age of 20 to 24 years. This long period of

"infancy" (as the biologist uses the term) is the period during which the individual achieves his racial inheritance. Infancy was evolved and prolonged to meet the needs both of racial inheritance and of individual learning.

The cycle of growth which begins with conception is therefore extremely complex. The human organism to some extent has to retrace previous stages of evolution. Accordingly, fetus and infant display physical and behavior traits which are reminiscent of primitive phases of the history of the race. But there is no evidence that the human individual ever fully reduplicates or rehearses early phyletic stages. The human infant from the beginning is human in make-up and in potentialities. Similarities between human and infrahuman behavior can be misleading, as emphasized by Madame Nadie Kohts who compared the behavior of a male chimpanzee during the age period from one and one-half to four years with that of her son from birth to

From *The Child from Five to Ten* by Arnold Gesell and Frances L. Ilg. Copyright 1946 by Arnold Gesell and Frances L. Ilg. Used by permission of Harper & Brothers.

A symbolic diagram of the growth processes which underlie the patterning of behavior. Six stages in the development of prehensory behavior are pictured: 1. At 12 weeks the infant merely looks at the cube; 2. at 20 weeks he approaches it with a bent arm; 3. at 24 weeks he grasps it with a palmar squeeze; 4. at 36 weeks he grasps with his fingertips; 5. at 52 weeks with forefinger and thumb opposition; 6. at 15 months he both grasps and releases adaptively; placing one cube upon another. He builds the tower in a twink. The twink is based on 15 months of post-natal growth time.

These reactions are made possible by patterned connections between countless neurons and muscle fibers. The connections are symbolically represented by the outgrowths of variegated neurons in brain and spinal cord. Neurons sprout and grow not unlike plants and trees. They put forth branches, sub-branches, end-tufts, and terminal arborizations. Threadlike fibrils extend from fingertips to cord and to cortex. A million nerve fibers unite the eye to the vastly complex jungle of neurons in the cortex. This living, patterned and patterning tissue affords an intimation of how the mind grows.

four years of age. She sums up her observations as follows:

(1) In the functional biological field: the chimpanzee *... ignores* the possibility of walking erect and of free-*ing* his hands for carrying weights, (2) In the sphere of imitation: the chimpanzee is devoid of imitation insofar as human sounds are concerned and generally fails to extend or improve his imitative behavior, (3) In respect of emotional, altruistic and social behavior: the chimpanzee fails to understand the advantages of friendly sympathetic intercourse with creatures standing on a lower biological level than himself, (4) With respect to habit-forming: the chimpanzee does not improve in the motor habits connected with the use of tools and household implements, (5) In the sphere of playful behavior: he does not indulge in creative constructional play . . . It is impossible to say that he is "almost human"; we must go even further and state quite definitely that he is "by no means human."

The Beginnings of Mental Life.—The patterning of human behavior gets under way remarkably early. By four weeks after conception the heart beats. By eight weeks, muscles and nerves have so far advanced that the fetus may stir, making a few simple movements of the head and trunk. By 12 weeks, the fingers flex and eyes move beneath fused lids. By 24 weeks, the chest is capable of rudimentary rhythmic movements. By 28 weeks, physiologic and behavioral functions may be sufficiently mature to insure the survival of a prematurely born infant, under modern conditions of pediatric care. The premature infant, however, gains no permanent lead over the full-term infant because the sequences and patterns of behavior are fundamentally governed by the genes.

The newborn infant is in possession of some 12 billion nerve cells which constitute his brain and sensorimotor nerves. This is the full quota, all that he will ever have. As the infant grows and as the child grows, these cells become organized into patterns of responsiveness and of reaction. In this sense the nervous system is the organ and the instrument of the "mind," of conscious experience, and of the residuals and promptings of past experience, sometimes called the unconscious. The nervous system, however, is part and parcel of the unitary organism; it is influenced by the constituents and states of the blood and body juices, by hormones and electrochemical regulators.

It is idle to ask where body stops and where mind begins. The infant cannot introspect and tell us when he becomes "conscious." There may well be glimmers and even states of psychic being in prenatal and the early postnatal periods of activity, for mind and action are closely allied.

Note the various action patterns of the four-weeks-old full-term infant. He uses his eyes adaptively. Dangle an object and move it slowly across his field of vision: his eyes will follow a short distance in active pursuit. He cannot freely rotate his head; he prefers to lie with head to one side; often he extends the arm on that side, crooking the other arm at shoulder level in a kind of fencing attitude. This is the tonic-neck-reflex posture. He holds and activates this posture from time to time, as though it were a developmental exercise. This is nature's method of preparing for the coordination of eyes and hands. Behavior is patterning. This is a manifestation of mental life. This is how the mind grows.

Even social behavior seems to be in the making. The infant regards the face of his caretaker. At favorable moments he heeds the human voice by diminishing his bodily activity. Occasionally small throaty sounds as well as

cries emerge from his larynx. He tends to quiet when securely held.

Thus we see that the newborn infant already gives developmental tokens of the four major fields of human behavior: motor, adaptive, language, and personal-social. These four fields are intimately interrelated, and no single field develops by itself. Each influences the other and the mind grows as a unit. It will be convenient, however, to discuss the fields individually in accordance with the following outline:

(1) Motor behavior: posture and locomotion; prehension and manipulation; gross and fine motor coordinations.

(2) Adaptive behavior: self-initiated and induced behavior; learning; resourcefulness in adjusting to new situations; exploitive behavior; intelligence.

(3) Language behavior: vocalizations; vocal signs; words; gestures; comprehension.

(4) Personal-social behavior: reactions to persons; response to gesture and speech; socialized learning; habits of self help.

Motor Development.—All told, a child has over 600 distinguishable muscles. These muscles, both fine and gross, are supplied by an extremely complex network of nerve fibers and fibrils. The tiny muscles which move the eyes are elaborately connected with the higher nerve centers of the brain; likewise, the delicate muscles which activate the larynx and the fingers are richly represented in the cerebral cortex. If a child were completely paralyzed, mind, as we know it, would be completely wanting. Perceptions, memories, intentions, desires, imaginings, and acts all have a motor basis. For this reason the story of mental development must be built around the acquisition of motor abilities and motor experiences.

Motor development proceeds from head to foot. It takes a full year or more before the infant stands alone and walks erect. First he "learns" to erect his head and to keep it steady on his shoulders. This is not true learning because the capacity depends mainly on a ripening or maturation of the controlling nerve structures. In due course he gains, by similar maturation, control of his arms and his trunk. First he sits by leaning forward using his arms as outriggers; later he sits upright without support. In due course, he pulls himself to his feet, cruises along the rail of his crib, and finally toddles off by himself on two feet. Walking is preceded by over 20 stages of prone behavior, including the swimming posture in which the baby at about 16 weeks of age arches his back, lifts his head, and lifts his legs in symmetric extension; pivoting at about 28 weeks; backward crawl, with abdomen on the ground surface at about 30 weeks; creeping on hands and knees at 40 weeks. Many infants toward the end of the first year creep on all fours—that is, on hands and soles. Soon soles alone suffice, and this frees his hands for carrying weights. Indeed, the erect posture was apparently evolved to emancipate the eyes and hands, so they might be used for higher purposes.

The motor coordination of eyes and hands advances by steady stages throughout the first ten years of life and into adolescence. For some 12 weeks the normal infant prefers the tonic-neck-reflex posture already mentioned. This is an asymmetric posture which undergoes growth changes: it leads the baby to look in the direc-

tion of the outstretched arm, to notice the arm in motion, to gaze momentarily and prolongedly upon his hand. At about 16 weeks, the infant prefers to hold his head in midposition, and to close in bilaterally with both hands upon an object dangled above his chest. This is the beginning of prehension. At 24 weeks he begins to reach unilaterally. At 28 weeks, having grasped an object, he transfers it from hand to hand. Early grasp is crude and pawlike, but at 40 weeks it becomes more delicate: the infant can pluck a pellet with precise pincer prehension, bringing thumb and index finger into opposition. Near the close of the first year, he "learns" to release a grasped object voluntarily. This new power of inhibition, like his earlier abilities, requires the maturation of higher nerve centers. It brings his growing motor abilities under increasing voluntary control. He begins to manipulate objects in an exploitive manner. He exercises his new-found power of release by inserting an object into a container. This behavior pattern reflects increasing intelligence and reminds us again that the mind is a unit and that adaptive, intelligent behavior is dependent upon motor developments and experience.

Practice and favorable experience tend to perfect motor performances; but the basic motor skills are untaught; they arise out of inborn sequences of development. For similar reasons, the genes play a primary role in determining handedness, eyedness, and footedness. Many children are by nature strongly right-handed or strongly left-handed; others are somewhat neutral, and to that extent are subject to custom and training. Deep-seated left-handedness, hereditary in origin, tends to show itself in a well-defined leftward tonic-neck-reflex posture in early infancy. Similarly right-handedness is manifested in a rightward tonic-neck-reflex. Hand dominance often shows itself clearly by the age of 40 weeks in spontaneous play activities; but marked interchangeability with considerable use of both hands is common at one and one-half, two and one-half, and three and one-half years of age. Nature does not place a premium on ambidexterity; unidexterity with auxiliary cooperation by the subordinate member is the rule.

A series of examples will indicate how the progressive development of motor abilities depends upon maturity factors. The two-year-old child can run without falling, and usually can walk up and down stairs alone. At three years he can jump from the bottom stair; at four years he can skip on one foot; at five years he skips using one foot and then the other alternately. He tosses and bounces and catches a ball at six years. At seven years he begins to be interested in learning to bat and pitch. At eight years he participates willingly in folk dances if he feels the rhythms and motor patterns dramatically. At nine and ten years the child displays increased self-motivated interest in acquiring motor skills.

Although there is a basic ground plan of motor development characteristic of the species and of stocks within the species, there are important individual differences reflected in variants of the ground plan. Some children are more motor-minded than others. They sense reality in terms of movements, manipulations, and postural attitudes. Such children may be

"slow" in reading, but they have compensating abilities. Verbal children, in contrast, may be adept in reading, but may lack other motor excellences. The degree to which handicapped children can overcome their motor disabilities depends largely on the available neuromuscular equipment and on strength of motivation.

Adaptive Behavior.—When sensorimotor equipment is put to self-initiated and induced uses, behavior takes on an adaptive, intelligent character. When the young baby begins to use his eyes in an inquisitive manner, to inspect his surroundings, he shows that his mind is at work. Whether we call his behavior reflex, voluntary, self-directed, natural, or intelligent is indeed a matter of semantics. We do know that an infant at 16 weeks of age may exhibit a veritable visual hunger. He frets when this hunger goes unappeased. He quiets when ocular and social stimuli combine to feed his appetite for visual experience.

This is the very time when the process of growth makes new demands upon his capacities to see. He must perceptually differentiate between his own hand and the hand of his caretaker, and the object which is proffered or which he holds. He was born with eyes, and with the potential tendencies to make the foregoing distinctions. If his inheritance is normal, he exercises his capacities at the appropriate level of maturity. If he is poorly endowed, or if his neuromotor equipment has been damaged by injury, disease, or defective genes, he may not display adequate adaptive behavior, even in the most elementary use of his eyes and hands.

Vision leads in the early growth of mentality. The baby takes hold of the physical world with his eyes before he takes hold with his hands. The next step in the development of adaptive behavior is to bring eyes and hands into coordination. Soon he begins to reach on sight; and having seized the object of interest, he exploits it by mouthing it, banging it, and rubbing it with whatever maneuvers his motor equipment permits. Eyes and hands now act in near unison, each assisting the other; visual cues and touch cues interact. The eyes are teamed as a pair; the hands are teamed as a pair; and the eyes and hands together and in alternation are likewise teamed. By an intricate process of reciprocal interweaving, the action system builds up patterns and propensities of adaptive behavior.

These patterns show themselves in his spontaneous and imitative behavior. It is instructive to see how he uses his intelligence in playing with blocks. At 24 weeks of age a typical infant grasps and holds a one-inch wooden cube; he makes an approach upon a second cube placed on a table within easy reach. At 32 weeks he picks up a cube in each hand and holds the two cubes prolongedly. At 40 weeks he brings them together in a midplane, in a pat-a-cake manner. Incidentally, he does not "learn" to play pat-a-cake until this age. Even his ability to imitate a nursery game depends upon his maturity.

At one year he can release a cube into a cup. At 18 months he releases one cube upon another to build a tower of three cubes. At two years he aligns the three cubes in a horizontal row. At three years he arranges them into a bridge. At four years he builds a gateway with five cubes, and at five years, a staircase of six cubes.

These patterns of adaptive behavior follow

each other in a lawful sequence. There are individual differences, but the general order of development is determined by a maturational ground plan. For this reason it is futile to attempt to teach a child to build a bridge at 18 months, and to play pat-a-cake at six months.

Similar sequences govern the manipulation of objects less material than building blocks, namely, words, sentences, symbols, and ideas. Through its schools, the culture begins to teach words in a systematic manner when the child reaches the age of six years. But here, too, his ability to adapt to words depends upon his maturity as well as his learning. Reading readiness, therefore, shows significant variations based upon inborn individual differences as well as upon methods of instruction. A relatively "average" child at the age of four may begin to identify capital letters; at five he is interested in numbers on the clock dial; at six he shows interest in small as well as in capital letters; at seven he recognizes familiar words out of context, and reads sentences in context; at eight he may even use a table of contents and index; and at nine he can utilize a dictionary.

With the aid of vocabulary scales and Binet tests, it is possible to appraise a child's intelligence in terms of his command of the written, the spoken, and the printed word. But both from a biological and a cultural standpoint, it is important to recognize that some children who are backward in reading and slow in speech, nevertheless may be highly intelligent and gifted in other less measurable areas of adaptive behavior.

Language and Thought.—Although there is no one-to-one correlation between verbal facility and so-called intelligence, the developmental relationship between language and thought is fundamental. Speech and visual perception are two of the most distinctive behavior features of the human species. It is not surprising, therefore, that these two functions undergo a long and complex development.

The newborn infant communicates by cries. He develops a vocabulary of cryings and frettings, the several meanings of which a discerning mother learns to differentiate. At four weeks the infant makes small throaty sounds; at 12 weeks he chuckles; at 16 weeks he laughs aloud. By 28 weeks he has in his babbling articulated such a rich variety of consonants and polysyllabic vowels that he gives ample promise that he will form words under the impress of the culture into which he is born. He may even grow up in a bilingual home and come out with two languages. By 15 months he jargons more or less volubly, as though he were carrying on a conversation. Jargon with all its rhythms and inflections seems to be the growth rudiment of phrases and sentences. In another year, jargon is shed. Three-word sentences emerge, and language becomes a useful tool. It serves not only for communication, but also for self-control. For example, voluntary control of bowel and bladder often coincides with the ability to name the products or process of elimination.

At four years, language burgeons. Hence the almost universal pleasure in nonsense words and silly language and rhyming at this age. At five years, the child shows a new interest in the meanings of words and uses language conformingly, asking "Is this the way to do it?"

At six and seven years, words are often asso-

ciated with magic powers. The child does not easily and consistently distinguish between fact and fancy; but with the aid of words he engages in private and expressed thinking about natural phenomena, life, death, superman, etc. The eight-year-old may speak with almost adult fluency. He can verbalize ideas and problems. He differentiates more clearly between fact and fancy. By ten years his thinking is still more critical; he often reduces his thoughts to writing and to diagrams. Alas, even as an adult he continues to have difficulty in making his thinking realistic and may succumb to the deceptions and black magic which sometimes lurk in words.

Personal-Social Behavior.—From the moment of birth the human infant feels the impacts of personal care and ministrations. He is an individual, but he is not an encapsulated ego. He soon begins to sense the unremitting attention which he receives. He senses it through passive touch, through hearing, and above all, through vision. He soon displays an amazing ability to read with his eyes the facial expressions, the gestures, the postural attitudes, and thereby the emotional attitudes of all the persons with whom he comes in contact. Paradoxically, his own personal sense of self is built up through these other persons—parents, siblings, playmates, teachers. The make-up of his personality depends greatly upon interpersonal relationships which he experiences from day to day and from age to age.

The child, however, is never completely made over by the culture. He retains a core of individuality, determined by the genes, by his stage of maturity, by intrinsic temperament, and by the inborn uniqueness of his particular pattern of growth. Nature, perhaps wisely, sets metes and bounds to his docility and amenabilities. At any rate, he must do his own growing, and he will regulate his personal-social behavior in terms of his insight and his capacity to profit by experience.

Social insight grows and patterns through a countless succession of interactions between the child and other persons. A one-year-old baby likes to repeat performances laughed at, thereby increasing both his own sense of self and his appreciation of others. Rolling a ball back and forth sets up a to-and-fro reciprocity with a partner. This illustrates a dynamism which operates throughout life in the organization of interpersonal relationships.

The problems of the child's social adjustment to other persons are by no means as simple as they appear on the surface. Even as late as the age of three, a child may not qualify for a hide-and-seek game because, ostrich-like, he thinks he can conceal himself simply by covering his eyes with his hands. Throughout childhood he may have difficulties in attaining the absolute perfections which the culture attempts to impose, even in such personal-social situations as table manners.

The culture must, of course, set ultimate goals of excellence. These, however, can be reached only by developmental gradations. Elsewhere we have detailed the growth gradients which underly the patterning of emotional and social behavior in infancy and childhood—gradients of anger, fear, affection, cooperation, competition; responsiveness to punishment and praise; the sense of good and bad, of ownership, truthful-

CHILD PSYCHOLOGY

1. Primitive kneel.

2. Swimming stage.

Over 20 stages of prone behavior precede the attainment of the upright posture and bipedal walking, six of which are shown here (above and to the right).

3. Pivoting crawl.

4. Frogging stage.

5. Creeping—hands and knees:

6. Creeping on all fours—hands and feet.

FOUR FUNDAMENTAL FIELDS OF BEHAVIOR.

Upper line: Posture and locomotion. Second line: Prehension and manipulation. Third line: Adaptive behavior. Bottom line: Personal-social behavior.

ness, and the like.¹ Skillful and effective child guidance depends upon a working knowledge of normal gradients of maturity on the part of teachers and parents. Humane discipline is impossible without recognition of individual and maturity factors. The so-called inherent badness of children has been exaggerated by distorting interpretations and traditions. Well-constituted children with healthy inheritance have an intrinsic charm—a charm which betokens inherent goodness. The growth potentials for good far outweigh those for evil, unless the cultural odds are too heavily weighted against the child.

Consult Carmichael, Leonard, ed., *Manual of Child Psychology* (New York 1946), for a comprehensive treatise and bibliographies on child psychology. For an account of the evolutionary background, consult Keith, Sir Arthur, *A New Theory of Evolution* (New York 1949).

Yale School of Medicine.

CHILD WELFARE. The welfare of all children calls for certain basic values in heredity and environment. It is rooted in the family and in the ability of the family to provide certain advantages, beginning with good breeding, and proper nourishment and care for the mother during the prenatal months, and followed by the physical and emotional nourishment which the infant needs. As the child grows, his physical, emotional, intellectual, social, and spiritual needs require an expanding array of services, including certain provisions by the family and also education, health, recreation, and religious and welfare services provided by the government or by voluntary agencies.

Traditionally, the term child welfare has been defined with special concern for the deprived child, with emphasis being placed upon physical, mental, emotional, and moral handicaps and problems, and upon the conditions and services necessary for the prevention or correction of handicaps. In view of the limited resources of families and communities, it is practical to make certain elemental provisions for all children, such as education and health facilities, and then to develop the services needed by those with severe handicaps, such as care, training, and treatment in their own homes, foster homes, or institutions for the dependent, neglected, delinquent, emotionally disturbed, mentally deficient, blind, deaf, or crippled. Whether it be defined broadly or in restricted terms, child welfare has extended its scope as standards of living have improved and as life has become more complicated.

Child Population of the United States.—The birth rate in the United States declined from 25.0 per 1,000 population in 1915 to 16.6 in 1933. It increased during and after World War II, reaching 25.8 in 1947, when the number of registered births, exceeding all previous records, was 3,699,940. Between 1940 and 1950 the number of children under 10 years of age increased 39.4 per cent. In many communities this additional child population overtaxed the hospitals and schools.

A comparison of 1940 census figures on child population and school enrollment with preliminary data from the 1950 federal census shows the following:

	1940	1950
Under 10 years	21,226,146	29,565,000
10 to 24 years, inclusive	35,667,293	33,420,000 ¹
Enrolled in school, 5 to 24 years	26,759,099	28,391,000

¹ Decrease due to low birthrate in the 1930's.

Federal and National Agencies Serving Children.—The welfare of children has commanded the attention of the various professions active in education, health, and welfare. In addition, service to children is the sole or partial function of scores of federal and national agencies. The numbers of child welfare organizations developed during the first half of the 20th century have required the expenditure of hundreds of millions of dollars annually.

Outstanding among the units of the federal government serving children are the Bureau of Human Nutrition and Home Economics and the Food Distribution Programs Branch of the Department of Agriculture; the Bureau of Indian Affairs and the National Park Service of the Department of the Interior; several units of the departments of Justice, Labor, and State; the Office of Education, the Public Health Service, and the Social Security Administration (including the Bureau of Old-Age and Survivors Insurance, Bureau of Public Assistance, Children's Bureau, and Division of Research and Statistics) of the Federal Security Agency; the Veterans Administration; the Displaced Persons Commission; and several coordinating bodies, including the Federal Inter-Agency Committee on Recreation and the Interdepartmental Committee on Children and Youth. Some of these federal units have counterparts in the governments of states, counties, and cities: for example, the state and local educational and health authorities and the welfare authorities administering various types of public assistance and child welfare services. The tendency for the federal government to subsidize certain health and welfare services through grants-in-aid has helped to develop similar interests in these federal-state-local governmental services. Federal aid to education became a hotly contested issue in the period 1939–1950, but no law or appropriation providing such aid developed. Even where services receive federal subsidies, the administration of the work is commonly in the hands of the local or, occasionally, state government, from which the bulk of the financial support for the services is derived.

If sectarian and fraternal organizations are included, voluntary national agencies serving children number several hundred. Many voluntary services in education, health, and welfare pertain only partially to children. This is true of the work of the American Legion (Indianapolis), with its National Child Welfare Division, which is only one of the Legion's several programs, and it applies also to the American Public Welfare Association (Chicago), the National Education Association and its affiliated bodies (Washington), and the National Association for Mental Health, the National Federation of Settlements and Neighborhood Centers, the National Probation and Parole Association, the National Recreation Association, the Young Men's Christian Associations, and the Young Women's Christian Association of the United States of America, all of which have their headquarters in New York City. Restricting their services to children are the Boy Scouts of America, Boys' Clubs of America, Camp Fire Girls, Child Study Association of America, Child Welfare League of America,

Girl Scouts of the United States of America, and the National Child Labor Committee, which also have their headquarters in New York.

White House Conferences on Child Welfare.—It has become traditional for the president of the United States at the end of each decade to call a conference in Washington, D.C., of persons qualified to study child welfare needs and resources. In addition to its inventory of conditions of children and services in their behalf, each of these White House conferences has been followed by substantial developments in child welfare planning.

The first such meeting, the White House Conference on the Care of Dependent Children, held in 1909 when Theodore Roosevelt was president, led to the establishment of the federal Children's Bureau (1912), and of the Child Welfare League of America (1920). The 1919 conference focused attention on the standards of various services to children and helped to bring about the regulation of child labor which subsequently developed in many of the states. Maternal and infancy services were promoted during the 1920's in every state with the benefit of federal grants-in-aid. Findings of the 1930 White House Conference on Child Health and Protection were recorded in 35 books and pamphlets on education, health, and welfare. The 1940 White House Conference on Children in a Democracy, with its membership limited to about 700, also considered a great variety of unmet needs and services. Follow-up work was in the hands of the National Citizens Committee, a nongovernmental body, and of a federal interagency committee. The National Commission on Children in Wartime, created in 1942, and its successor, the National Commission on Children and Youth (1946), did some of the preliminary planning for the Mid-century White House Conference on Children and Youth, held Dec. 3-7, 1950. This conference, larger than its predecessors, was attended by more than 5,000 persons, including representatives of all large citizen and professional bodies, of whom about 500 were youth delegates. These young people participated freely in discussion and study groups and in the plenary sessions of the conference.

The 1950 conference was preceded by extensive regional and local studies of child welfare needs and resources by committees or other bodies appointed by state governors. Some of these organizations were designed to operate after 1950 to continue such planning as might be needed in view of their studies and of the findings of the White House Conference. In 1949, public welfare and voluntary agencies providing foster care and related social services in Oregon arranged to have the Child Welfare League of America make a survey of their operations and a study of unmet needs.

The general theme of the 1950 conference was: "To consider how we can develop in children the mental, emotional and spiritual qualities essential to individual happiness and to responsible citizenship, and what physical, economic and social conditions are deemed necessary to this development." The inclination to account for child development as well as the specific needs of children was reflected in many of the conference's 67 recommendations, as well as in the preamble, the resolutions on following up the work of the conference, and the pledge to children approved at the closing sessions. The com-

prehensive nature of the findings was reflected in two recommendations:

(1) "That all professions dealing with children be given, as an integral part of the preparation, a common core of experiences dealing with fundamental concepts of human behavior, including the need to consider the total person as well as any specific disorder; the interrelationship of physical, mental, social, religious, and cultural forces; the importance of interpersonal relationships; the role of self-understanding; and emphasis on the positive recognition and production of healthy personalities and the treatment of variations; and that lay people be oriented through formal or informal education to an understanding of the importance of the foregoing concepts.

(2) "That steps be taken at national, state, and local levels to improve the facilities and increase the output of professional schools preparing persons for services to children."

The conference at times resembled a huge town meeting, with many of the 4,620 voting delegates desiring to speak and scores of them having the opportunity to do so. Among several controversial measures which in original or amended form survived the plenary sessions were (1) a decision to support the program recommended by the President's Commission on Civil Rights and specifically to appeal to the federal government to abolish segregation in the nation's capital, and provide there an example of a truly working democratic absence of discriminatory practices on the basis of race, creed, or color; (2) an affirmation of the essentiality of religious and ethical concepts in the development of spiritual values and the importance of religious education in homes, families, and institutions of organized religion, but also an affirmation of the principle of separation of church and state as the keystone of American democracy and a declaration of unalterable opposition to the use of the public schools directly or indirectly for religious educational purposes; and (3) approval of further federal aid to the states for educational services, in tax-supported public schools, without federal control, to help equalize educational opportunity—the issue of auxiliary services to be considered on its merits in separate legislation.

Child Health.—The chances for a child to remain alive and healthy were greatly improved during the first half of the 20th century. The mortality of children under one year of age in the United States declined from 99.9 per 1,000 live births in 1915 to 29.2 in 1950. Contributing to this progress were the increased use of hospitals for maternity care; the expansion of prenatal clinic services; the increased skill of obstetricians, nurses, and midwives; and the development during World War II of the Emergency Maternity and Infant Care program financed by the federal government and administered by the Children's Bureau. The proportion of white children born in hospitals increased from about 40 per cent in 1935 to more than 90 per cent in 1948; for Negro children in the same period the proportion rose from about 18 per cent to more than 50 per cent. Parent education in the care of children, especially of infants—a major factor in the improvement of child health—has been advanced by the distribution of millions of copies of pamphlets and books written by capable health authorities. Federal and state health agencies make some of these publications available free of charge. Nutrition has become more adequate as family in-

comes more commonly permit the purchase of wholesome food. Milk and other dairy products, as they have become more plentiful, are increasingly safeguarded by pasteurization. In addition, by 1951 one fourth of all children enrolled in elementary and secondary schools in the United States were participating in a national school lunch program.

Public health agencies provide badly needed preventive and protective measures, especially in the improvement of sanitation and in the widespread administration of prophylactic measures against several of the diseases which were characterized by high mortality rates at the beginning of the 20th century. By 1951 the number of children dying annually from diphtheria, typhoid fever, and paratyphoid fever was a small fraction of the toll taken by these diseases in 1900. Smallpox has been practically eradicated in the United States. Improved medical and nursing services and the use of modern drugs have reduced greatly the severe complications and deaths formerly caused by measles, scarlet fever, whooping cough, influenza, pneumonia, and tuberculosis. Poliomyelitis and rheumatic fever have also responded to improved treatment, although by 1951 the causes and prevention of these diseases had not been established by research. Cerebral palsy has crippled many children, and measures have been taken in many urban communities for their treatment and education. Estimates of the number of handicapped persons in the United States under 21 years of age in 1951 were as follows: rheumatic fever, 500,000; epilepsy, 300,000; poliomyelitis, 200,000; cerebral palsy, 150,000; other orthopedic handicaps, 400,000; deafness and seriously impaired hearing, 750,000; blindness and serious visual defects, 67,000.

A three-year study of child health services and pediatric education in the United States by the American Academy of Pediatrics allowed publication in 1949 of a widely accepted report (see *Bibliography*). The study was made with the cooperation of the Public Health Service, the Children's Bureau, and other health agencies. It listed four reasons why a large number of children had not received preventive and curative care compatible with acknowledged standards of good pediatric practice: (1) Parents were unable to pay for good service. (2) There was unwillingness to use, or lack of knowledge of, available facilities. (3) Services were not available within a reasonable distance. (4) There were not enough physicians well trained in the medical care and health supervision of children, especially in rural areas. The study revealed that New York had eight times as many dentists in relation to children as South Carolina, and four times as many in relation to the total population. It showed that general practitioners, many of whom were without internship training in pediatrics, handled three fourths of the medical care of children. In addition to the need for more pediatric education in medical schools, the study showed a disproportionate concentration of pediatricians in urban areas and a serious scarcity of child health services and pediatricians in rural areas.

Universities; federal, state, and local public health agencies; and such foundations as the Rochester Child Health Project (Rochester, Minn.), the Rockefeller Foundation, and the Children's Fund of Michigan have undertaken extensive research in various areas of child health. Traditionally the physical aspects of child devel-

opment have received attention, but there has also been an increasing tendency to study the emotional needs of children from infancy to adolescence.

Recreation.—Throughout the ages children have been able to play even under adverse conditions. Recreation has helped them to develop strong bodies, balanced personalities, abilities in social relations, imagination, and many skills. The organization of recreation has become characteristic of life in the United States. The production of materials and the operation of facilities have involved large expenditures by families, churches, schools, neighborhood and community organizations, and federal, state, and local governments, and commercialized recreation has become a major industry.

Several factors have led families to spend much time and money on recreation. To the extent to which the activities are wholesome, they offset some of the influences tending to weaken family life. A shorter working day and week and increased family income permit parents and children to enjoy swimming, skating, fishing, hiking, boating, motoring, and a great variety of arts and crafts. Motion pictures, radio, and television also often keep families together.

Most of the auspices under which recreation is organized represent a concern for the healthy development of children, but some of the commercial facilities and some of the play organized by gangs contribute to juvenile delinquency. Successful efforts to redirect the interests and activities of street gangs have been made by such organizations as the Police Athletic League in New York City and numerous neighborhood houses, some of which employ professionally trained group workers. Municipal recreation commissions have been developed even in small cities, and many suburban counties have such bodies. Most of these governmental projects include year-round activities which are expanded during summer vacation months.

There is great variation in the quality of facilities and leadership. Except for maintenance purposes and safety provisions, many parks, swimming pools, beaches, tennis courts, and other outdoor recreation centers are often without supervision by trained workers. Playgrounds and indoor facilities, however, are generally under the direction of leaders competent to organize and supervise sports, dramatic productions, crafts, and social activities. The recruitment and training of such leaders constitute a major service provided by the National Recreation Association. Many universities offer graduate study for those who wish to specialize in recreation, and most large recreation programs, whether under governmental or voluntary control, provide in-service training for their workers. In some parts of the United States this is one of the responsibilities of state recreation authorities.

Rural young people have been organized for recreation and other activities. Four-H clubs have thrived as motor transportation has made it easier for farmers and their families to get together, and granges, cooperatives, and other organizations have developed the social interests and activities of a large part of the rural population.

Camping has become a major recreational activity which in turn utilizes many activities. Most camps are operated on a nonprofit basis, but many are directed by a proprietor who

charges a fee large enough to make the project profitable. Pioneers in the development of summer camps on a nationwide basis were the Young Men's Christian Associations and the Boy Scouts of America, both of which have developed programs of training for camp directors and extensive literature pertaining to standards for the operation of camps. These and many other national agencies interested in camping and individuals experienced in camping have organized the American Camping Association (Chicago). Most camps aim at developing happy, healthy, self-reliant children. Some add to these objectives such specialized functions as music education, training in dramatics, and treatment for children with physical or emotional handicaps.

Play therapy has been developed by leaders in the fields of mental hygiene and psychotherapy. Research, mostly since 1930, has indicated great possibilities in this type of group work. Small groups and specially trained leaders, operating with supervision or in consultation with a psychiatrist, are essentials in a service so difficult and complicated.

WELFARE OF HANDICAPPED CHILDREN

The number of children in the United States who are dependent, neglected, delinquent, crippled, convalescent, emotionally disturbed, or mentally deficient cannot be given, partly because the legal or practical definitions of these handicaps vary from state to state and even within the same state, and partly because there are few comparable records of those needing service but unable to obtain it. Even the simpler task of accounting for those living in various types of foster homes, institutions, and residential schools has been accomplished only in part. Nor is there any enumeration of the children who receive day care, many of whom are served by women who operate facilities for profit in some communities without the requirement of a license from health or welfare officials. It was estimated at the 1950 White House Conference that one out of five mothers with children under 18 years of age works outside the home.

The federal census of *Children Under Institutional Care and in Foster Homes*, 1933 was published in 1935. Partly due to wartime economies, no such enumeration was made in 1943. The United States Office of Education in 1946 published lists of various types of residential schools, including training schools for juvenile delinquents and the mentally deficient. There then were 201 training schools for juvenile delinquents in 51 states and territories, including the District of Columbia, of which 138 were governmental and 63 were under nonsectarian or sectarian control. Children in residence then totaled 32,447. In November 1949, the United States Children's Bureau published a directory of public training schools for delinquent children, listing 171 institutions with their capacities but not their populations. The training schools for the mentally deficient numbered 163 in 1946 and were located in 45 states and territories. They reported 110,207 persons in residence, but it was not indicated how many of these were children. Chronological ages seem less important than mental ages in work with the mentally deficient; and it is not uncommon to designate as boys or girls men or women who have passed their 21st birthday.

The 1933 census report showed the number of

dependent and neglected children in foster homes to be 102,577; in institutions, 140,352. Although exact numbers have not been determined since this census, the data gathered for the 1950 White House Conference showed about 105,000 children in foster homes under the care of public welfare agencies. Those under the care of private agencies totaled about 50,000. It was reported by the Children's Bureau that about 375,000 children, including those under foster care, were receiving social case work service from public and private agencies on June 30, 1950.

Crippled and convalescent children receive care at home or in foster homes, in various types of hospitals, and in specialized institutions. The states and territories maintain registers of children who have been diagnosed by a licensed physician as having a crippling condition, but these lists admittedly are incomplete and do not reflect the number of children receiving care because they are crippled.

It is impractical to attempt to count or estimate the number of emotionally disturbed children under care in foster homes or institutions, or the number in need of such care. There is none of the legal definition of this condition that exists in services to the dependent, neglected, delinquent, and mentally deficient, although during the period 1931-1950 a number of institutions with service to emotionally disturbed children as their principal or sole function were founded or reorganized. Their clients naturally have been only the seriously disturbed, and in most states there are no facilities even for such children.

Although the exact number of those needing foster care and related services cannot be determined, it is known that in some communities there are no facilities for certain children, and that in places the facilities available do not provide for all who need them. The shortage of foster homes for children of all ages has been advertised in popular radio and news campaigns for additional homes. The lack of foster home care has been especially serious for Negro children, and there is a dearth of institutional care for Negroes even in states where segregation in such services is not the common practice.

Preventive Measures and Services.—The extent of dependency, neglect, delinquency, and emotional disturbance among children in the United States would be much greater than it is were it not for the availability since 1936 of several types of social security, notably aid to dependent children (ADC); the development since about 1925 of child-guidance clinics and related services operated by schools and social agencies; the establishment in many communities of family welfare and family counseling services; the expansion of religious services and influences; the organization and development of recreational services; the provision of probation service by juvenile courts; the increase in the facilities for day care; and the widespread development of nutritional and health services.

In January 1951, ADC was provided for 1,639,107 children in 641,397 families. The funds for ADC are derived from both federal and state appropriations, the federal government supplementing the amount provided by each state on a grant-in-aid basis. Aid is available to a parent, or to any relative of second degree providing a home for a child, who satisfies county or other local public welfare authorities that this form of assistance is needed. Unless the relative

with responsibility for the care of the child has established legal residence, however, the family is ineligible for ADC or other forms of public assistance in many states. Settlement laws have been liberalized in a number of states, however, and by 1950 seven had abolished statutory residence requirements for ADC.

Were it not for ADC, the number of children in foster homes or institutions might have doubled or trebled in the period 1936-1950. Between 1940 and 1950 the population of the United States rose 14.5 per cent, or by more than twice the percentage of the preceding decade, due mostly to an unprecedented increase in the number of children born. Yet there was no proportional increase in the number of either of the two types of foster care. An undetermined increase in the need for child care during and after World War II was reflected in the waiting lists of children for whom service in foster homes or institutions was unavailable. These facilities were noticeably insufficient for infants, adolescents, and Negro children of all ages. In addition to ADC, factors tending to keep families together have included increased wages, unemployment benefits, the reduction in illnesses among workers due to improved diet and health services and industrial safety measures, and the rehabilitation of disabled workers.

Valuable as ADC has been in the prevention of neglect and extreme dependency of children, in most states the grants have been too small to permit fulfillment of its avowed purpose. The increases authorized by most state legislatures have lagged far behind the rise in the cost of living. Recognizing the inadequacy of ADC, the United States Congress, in its 1950 amendments to the Social Security Act, added to the federal contribution for this form of assistance up to \$27 monthly for each family aided to help defray the expenses of the parent or other relative assuming responsibility for the care of the needy child or children. Even this addition left the grants so inadequate in some states that voluntary agencies, including several sectarian children's institutions in the South, provided a monthly supplement to the ADC grant for families which otherwise might have been compelled to send their children to live in an institution or foster home. In January 1951, the average monthly ADC grant per family aided ranged from \$18.38 in Mississippi to \$123.79 in Massachusetts. The inadequacies of ADC have been conspicuous because the United States is the only large industrial country without a system of children's allowances, commonly called family allowances.

Child welfare services are a major responsibility of the Children's Bureau. Under title 5, part 3 of the Social Security Act of 1935, the bureau makes grants-in-aid to state public welfare agencies in order to help them extend and strengthen, especially in rural areas and areas of special need, public welfare services for the protection and care of homeless, dependent, and neglected children, and children in danger of becoming delinquent. The services of child welfare workers thus made available have been used by families, neighbors, schools, courts, and other agencies to ascertain how the needs of socially deprived children can best be met.

The 1950 revisions of the Social Security Act included authorization of aid for the return of children who run away from home to another state in cases in which such return is in the

interests of the children and the cost cannot otherwise be met; and a provision that, in developing public child welfare services, "the facilities and experience of voluntary agencies shall be utilized in accordance with child-care programs and arrangements in the states and local communities as may be authorized by the state."

Boys or girls whose delinquency has brought them to a children's court or court of domestic relations are often returned to their parents under some plan acceptable to the court and to the parents. Some of these children are kept under the supervision of the court's probation staff. Probation is often used in preference to commitment to a training school for delinquents, such commitment still being too commonly the recourse of those courts operating without probation officers or courts in which neither the judge nor the probation staff is professionally qualified to understand and serve children. In only about half of the 3,069 counties in the United States is there provision for probation service in courts with jurisdiction in juvenile cases, and many probation officers are untrained. Probation may be provided for a child in his own home or in some place outside his home. The use of the homes of relatives, foster homes, institutions for dependent and neglected children, boarding schools, and centers for the study or treatment of emotionally disturbed children allows flexibility in dealing with the varied individual and family problems underlying delinquency. Just as ADC often prevents dependency from becoming acute, so probation permitting the effective use of various facilities by the court avoids the confirmation of delinquency so frequently resulting from commitment to a training school for delinquents.

Child guidance services provided by school social workers and child guidance clinics have proved highly effective in the prevention and correction of severe emotional disturbance and delinquency among children. The early detection of emotional distress or wayward tendencies in a child may spare him mental illness or delinquency and the unhappiness such maladjustments, if ignored, will impose. It has become obvious that teachers in elementary and secondary schools are able to detect such problems, just as they note obvious physical handicaps in time to permit early treatment. Social workers, as they become acquainted with children and families, also are in a position to refer children for psychiatric service during the early stages of behavior disorders. Thus the staff of a child guidance clinic can obtain results earlier and can be more effective than in cases when the child comes with a long-established pattern of disturbance or misbehavior. Juvenile courts increasingly rely upon the psychiatric services of child guidance clinics, and a few courts have their own psychiatric staffs. The development of mental hygiene and child guidance services during the period 1921-1950 has helped court officials and the general public to understand that many delinquents are so disturbed emotionally as to need treatment, and that the root of most delinquencies may be found in emotional disturbance. Many of the emotionally disturbed, however, are not delinquent. Serious and prolonged disturbance may lead to mental disease requiring treatment and care in a mental hospital by the time the child becomes an adolescent or an adult. Other children are restricted only in

their ability to live happily and effectively because of the depression or confusion which typifies their distress. Fortunately, most of those in need of psychiatric service can be treated while living at home and without interruption of their education, work, or other activities.

Remedial instruction for children with neurological, emotional, or mental handicaps, provided in the schools or on a tutorial basis, is another corrective measure developed since the early 1920's. Without such assistance many with reading difficulties grow up unable to read a newspaper or working instructions. Unless they are given corrective training, those with faulty speech also find difficult or impossible ordinary communication essential in obtaining employment or in living happily with others. Earlier in the century, and in many communities even in 1951, youth and adults with such handicaps were tragically misjudged and were frequently considered mentally deficient.

Special classes in the public schools permit many mentally deficient children to learn enough to compete with their more intelligent fellows in industry and other occupations and to function as useful members of society. Without this help many such children would flounder in unsuccessful efforts to learn under the ordinary curriculum and would become discouraged and defeated.

Family welfare services, available in most large cities, were founded in the 19th century as voluntary agencies providing relief. As public welfare became more adequate and as social security became available, most family service societies greatly reduced their relief programs. Increasingly, their efforts have been concentrated on social case work and related services whereby families are strengthened, individuals are aided to develop effective social relationships within and outside their families, and families and individuals are helped to meet problems which threaten their welfare. The prevention of family disintegration by such agencies has reduced the number of children needing foster care. Family service societies have also been effective in rehabilitating families, thus allowing children who have required foster care during a period of crisis to return to their homes when the crisis is over.

Homemaker service, developed in only the largest or socially best-equipped cities, is one of the most effective services holding families together when illness or other emergency situations remove the mother or place her temporarily in need of assistance. When a mother is in confinement, and sometimes after her return from the hospital with a new baby, a homemaker operating under the supervision of a social agency looks after the other children. The economy of this service is obvious, especially in large families where it would cost much more to place several children in foster care than to pay the salary of a homemaker. In terms of the emotional security provided for children, it warrants further organization and use.

Visiting nurses have played an important role in reducing morbidity and mortality among children. In addition to their own services, they contribute to the community's efforts to prevent the development of serious health and welfare problems by referring families to other agencies when there is still time for preventive services.

During World War II day care became one of the best-known and most widely used com-

munity services to children. Congress authorized the subsidy of child care centers by including day care among the activities covered by the Lanham Act of 1942. Under its appropriations religious and nonsectarian agencies expanded existing day care services or established new day nurseries. These services were insufficient to care for the large number of preschool children whose mothers were absent during the working day and who had no other adult in the home to provide supervision. Consequently, many independent proprietary day care services were organized, some of which were of good quality, but many of which were seriously substandard. With all its inadequacies during and after the war, however, day care has been a valuable and economical child welfare service without which many children would have been sorely neglected and in danger of serious accidents, ill health, or associations predisposing them to delinquency.

Other preventive measures and services might be listed, but these well-known provisions illustrate the tendency of professional workers and those responsible for legislation and social planning to attack the causes of child welfare problems. This trend is important in view of the palliative efforts, sometimes under unskilled leadership, whereby communities traditionally still provide for children handicapped by dependency, neglect, delinquency, emotional disturbance, or mental deficiency.

Dependent and Neglected Children.—

Services to dependent and neglected children in the United States, rooted in the customs of other lands and notably in the English poor laws, have grown from meager and often miserable beginnings. The indenture of children, which placed as much emphasis upon the services that the child was to perform as upon his shelter, clothing, food, and training, placed a price on the child and what he was to give and receive. The care of children in almshouses, where they lived with indigent, diseased, and sometimes vicious adults was common in the 19th century and still persisted in backward communities even after 1900. Placement for adoption or care in other types of foster homes took the place of indenture; and the orphan asylum, orphanage, or children's home displaced the almshouse for purposes of child care and the relief of dependency and neglect. Even though indenture is no longer tolerated, a practice almost as questionable—though in many states illegal—still exists in the placement of babies for adoption by individuals who receive a substantial payment for each child thus purchased. Less objectionable but also undesirable are the substandard services found in family boarding homes and children's institutions due to inadequate budgets; lack of skill in administration, social service, and child care; and overloads carried by social workers, foster mothers, and institutional personnel. The evolution of child welfare will proceed only at a slow pace in many communities until radical changes have been made, especially in the displacement of unskilled leaders by workers professionally trained to serve children.

Among the most important changes in the 20th century have been the improvements in service whereby dependency, neglect, and other handicap may be identified. The professional education of social workers, psychiatrists, and others engaged in child care has been paralleled by the development of organized services essential to the suc-

cessful treatment of children's problems. Social case work as practiced in family service societies, children's aid societies, adoption agencies, and various types of institutions has placed emphasis upon understanding the relationships within families and the development of children. The social worker, sometimes designated as the case worker, usually emphasizes rehabilitation of the family, wherever practical, and the development of well-balanced personalities. As this influence has been felt, the average length of the period of care or treatment required for dependent and neglected children has been shortened. In 1920 it was common for children to remain in a foster home or institution for 5 to 10 years or even longer. A few children need such long-term care even where there is adequate social case work. But the average period of care required by most dependent and neglected children may be measured in months instead of years. The progress thus made is comparable to the improvements in surgery and hospital care whereby a person recovering from an appendectomy in 1951 remained in the hospital less than half the time common for such patients in 1930. The social economy reflected in this shortening of the length of foster care, both in foster homes and institutions, may be measured in different ways. It means conservation of family ties, which are apt to be weakened or severed if a child is separated from his parents for years. The child and family derive greater security when they are reunited at the earliest time consistent with wholesome relations. The space in the foster home or institution will serve more individuals within a year than when long-term care was common. Some institutions, with the same number of children in residence on a given day, served twice as many in 1951 as they did in 1930. Even though the per capita daily cost of child care rose sharply because of the increased cost of living and the much needed improvements in service, the total cost of a child's care was less in 1951 if he remained under care only six months as compared with the two years he might have remained in 1930.

A double burden of dependency and neglect is often observed by those who serve children requiring foster care. The economic, physical, mental, and emotional pressures which create dependency in a family may also make parents neglectful. Moreover, the parent inclined to neglect his child because of emotional conflict and confusions in his family relationships is apt to have his earning power curtailed and his ability to support his child reduced to the extent that dependency is created. The two conditions do, however, exist separately.

A child may be dependent and still have one or both parents who love him and are capable of satisfying his basic emotional needs. A widower or widow may be unable to earn a living and also to maintain a home, and be compelled to ask a social agency to accept one or more of his or her children for foster care. The parent confined to a hospital with a long illness, as with tuberculosis, may require for medical and hospital expenses the funds needed to maintain the home and to provide substitute parental care. In most states it is a simple procedure for the city or county department of public welfare to commit such a child to a child-placing agency or institution, with the understanding that the parent will pay something toward his support if the

family budget permits. Whether there is such payment or not, it is common practice for the committing authority to return the child to his parents when they are ready to provide a home for him. In a few states and local jurisdictions the law requires the action of a juvenile court before a child may be declared a dependent and be entitled to support as a public ward. Increasingly, since the passage of the Social Security Act of 1935, and the subsequent development of child welfare services by county welfare authorities, the courts have left to these authorities jurisdiction in all matters pertaining to dependency. Such jurisdiction has been provided for in the revision of children's codes in several states. Dependency is often recognized by voluntary arrangements between a parent and a nonsectarian or sectarian child-caring agency or institution. In the first quarter of the 20th century there was a tendency for such organizations to have a parent sign a formal surrender of his child. Legal decisions repeatedly declared such surrenders invalid when a competent parent claimed his child in opposition to the claim of a social agency reluctant to return him. Another reason for avoiding the use of surrenders is the tendency of social workers and social agencies to do all they can to keep intact those economic and emotional ties between parent and child which the act of signing a surrender tends to dissolve. Sometimes physically handicapped children requiring prolonged hospitalization are declared legally dependent in order to permit public authorities to pay for all or part of their treatment.

A neglected child is one whose relatives or guardians fail to perform their duty, do not provide a proper home, do not care properly for him, or treat him with cruelty. There are various degrees of neglect, ranging from the failure of a mentally deficient parent to support his child to the willful rejection by a parent of one or more of his children (as in cases of abandonment), the instruction of a child in immoral practices, or the use of physical punishment which injures the child. Extreme neglect may warrant depriving the parent of his rights as guardian and custodian of his child. In contrast to dependency, neglect may require the action of a juvenile court in transferring guardianship, custody, or both to a child care agency or to a responsible and interested individual, or in requiring a parent to contribute to the support of his child. Such court orders sometimes are issued to fathers of children born out of wedlock whose paternity has been established by legal action.

Much of the neglect of children reflects only the ignorance, immaturity, or emotional distress of one or both parents. Consequently, children's protective services operated on a case work basis seek and obtain the cooperation of most parents against whom complaints of neglect are filed. Parents whose neglect of their children has been serious or even cruel respond in some cases to sympathetic and skillful efforts to help them understand their children and themselves. This development is in contrast to the authoritative and even punitive attitude of the early efforts of children's protective societies, and of some of the social service still provided in 1951 on that basis.

Juvenile courts and courts of domestic relations may also be classified according to their inclination to obtain the cooperation of parents or to coerce or punish them. In most cities and

counties in the United States there are no children's protective societies. In such communities the police, public welfare workers, and the court probation officers respond to complaints of the neglect of children.

Even where neglect warrants the removal of a child from his parents, there is a tendency to rehabilitate the home when it seems in the best interests of the child. In certain cases where there is improper guardianship, however, parents are even denied the right to visit their children in the foster homes or institutions to which they have been committed. Those who work effectively with neglected children acquire legal knowledge, especially with reference to guardianship and custody. A publication of the Children's Bureau helpful in this connection is *Guardianship: A Way of Fulfilling Public Responsibility for Children* (see *Bibliography*).

Improved services for children, especially in the fields of health and welfare, are patronized increasingly by parents, able to pay for the entire cost of service, whose children cannot be classified as dependent or neglected. Many widowers have found the employment of housekeepers unsatisfactory and have turned to child-placing agencies for foster home care for their children. Families of children who are emotionally disturbed or who have other handicaps often find in foster homes or institutional care of high quality the best available service. The second half of the 20th century may see extensive use of such services by those able to pay all that it costs, just as the first half of the century saw the use of hospitals by private patients become increasingly popular.

Care in Foster Homes.—The care of dependent and neglected children in foster homes is given mostly in boarding homes. Other types are adoptive, free, wage, and work homes. Boarding homes include subsidized foster homes, used especially for temporary care, where experienced foster parents are ready day or night to receive children in need of emergency shelter or detention. In such a home a fixed payment is charged for each bed kept available even when it is not in use, and a larger amount is paid for each child under care. There are also specialized foster homes for specially handicapped children, where a physical or mental infirmity receives the attention of a nurse who is also the foster mother. Dependency or neglect is usually an additional handicap of such children, who otherwise might have nursing care in their own homes.

Adoptions usually involve infants, most of whom are the children of unmarried mothers. There is a tendency to arrange adoptions for a few older children, including those of school age—children without relatives to provide suitable care who otherwise would spend years in boarding homes or institutions. The demand for babies consistently has been greater than the supply of those available for adoption, even though an increase in the number of children born in the United States, including an increase in the number born out of wedlock, has overtaxed the facilities of accredited adoption agencies. Such agencies first screen the large numbers of applications of couples seeking to adopt children and then study carefully the family situation of those who satisfy the initial requirements. By 1951 adoption studies, which in earlier years were usually superficial, stressed the emotional stability and compatibility of the adopting parents and their capacity to love an adopted child until he should become an adult,

with due attention being given to the ability of the foster parents to maintain a home and to provide the religious, moral, and social influences expected of parents. It is customary to approve for adoption of babies only those foster parents under 40 or 45 years of age. Common practice, required by law in most states, allows the completion of adoption only after the child has lived in the foster home for a trial period of a year or more.

In contrast to the oversupply of adoptive homes is the scarcity of boarding homes. The radio, press, and other channels of communication have been used in campaigns to recruit this type of foster home. Factors restricting the supply of suitable boarding homes are the scarcity of housing; the construction of apartments large enough only for childless couples; the demand for women workers in business, industry, and the professions; and inadequate rates of board paid to foster mothers. The need for boarding homes is especially acute for Negro children and for those of other racial groups for whom suitable housing has been scarce because of discrimination and other disadvantages. Rates of board were doubled by many child-placing agencies during or after World War II. The study of the situation by the Child Welfare League of America and other organizations led to the analysis of board rates and to more adequate provision for the expenses of those caring for a foster child. Basic rates for board commonly include amounts covering the child's share of the family budget for food, laundry, fuel, light, and rent. In addition to the basic rate, the payment for board usually includes the cost of clothing, school supplies, transportation, haircuts, and spending money. A few agencies also add an amount to compensate the foster mother for her services. In 1951, however, the situation was still complicated by rates of board so low as to require foster parents to be philanthropists to the extent of paying for several of the items essential or desirable in the care and training of their foster children.

Serious hazards in foster home services are the circumstances, sometimes unpredictable, which require re-placement of a child, and the inclination of some social workers and agencies to use substandard homes or to place in one home more children than the foster mother can properly serve. The law in many states limits to six the number of children who may be cared for in one foster home and requires the licensing of foster homes by a public welfare agency. The scarcity of qualified social workers, the limited budgets of child-placing agencies, and the insufficiency of foster homes have led to the overloading of workers responsible for finding and supervising foster homes.

Reliance upon free foster homes has decreased as the use of boarding homes has increased. At one time large groups of children from Eastern cities were taken by child-placing workers to the Middle West, mostly for placement in rural homes; this practice was discontinued by 1920. In several respects these free home placements resembled indenture. The foster parents chose the child with little or no study of their qualifications to provide suitable care and training; there was no regular supervision of the child after placement; the placements were too far away to permit visits by the child's relatives; placement at a distance discouraged efforts to return the child to his parents; and in most cases the child's fitness as a farm or domestic helper, or the likeli-

hood of his becoming a capable worker, was implicit in the application for a child. Many states have statutes controlling and discouraging the placement within their boundaries of children from other states, and bonds are required in some jurisdictions before an agency may bring a child from outside the state for placement in a foster home. There continues to be some use of free homes and some reliance in the care of adolescents upon wage or work homes. With skillful home finding and supervision there is a place for these types of care, although they are suitable for only a few of the children needing foster homes.

Care in Institutions.—There are in the United States approximately 1,600 institutions serving dependent and neglected children. Of this number, about 400 are under Protestant sectarian auspices, almost 400 are operated by the Roman Catholic Church, and a few are run by Jewish organizations. More than 500 are under non-sectarian control, and about 200 are operated by state or local governments. Approximately 10,000 of the 140,000 children in such institutions are in those under government administration. This proportion is in contrast to that prevailing in foster home service, in which about two thirds of the children are under the care of government agencies. Approximately three fourths of the institutions have fewer than 100 children in residence, and it has become increasingly common for them to provide for some of their children in foster homes.

Most institutions built since 1910 have utilized the cottage plan, the group in each cottage ranging from 10 to 25. There are some cottages for more than 25, but child welfare authorities are inclined to consider these larger living groups as congregate units. In the 19th century most institutions were congregate, sometimes with 100 to 500 children living in one building and 40 or more children sleeping in one room.

Institutional care, typified by function, includes temporary service for purposes of shelter; reception, pending placement in foster homes or referral to other institutions; and observation or study. Where residence for several months or years is anticipated, the institution usually regards foster care as its primary responsibility. For older children training is often an avowed purpose, very much as in a boarding school, and this training may include prevocational activities or preparation for study beyond high school. Some institutions are inclined to specialize in the treatment of emotional problems or handicaps which require remedial teaching, this policy being based on the presumption that most children uprooted from their own homes are confused or disturbed to the extent that they need these specialized services. A modern institution regards itself as an advocate for the child, providing the social service necessary to safeguard such kinship ties as he possesses and to prepare for his return to his family. Visits by parents are encouraged, and plans are often made for children to spend holidays with relatives. This type of service is quite different from the custodial service which formerly characterized most institutions and often is still found where no social case work has been done in behalf of the child and his family, and where a child's admission to an institution is considered the complete plan instead of one step in dealing with his dependency or neglect. Increasingly, institutions provide a balanced service in which social worker, teacher, physician, dentist,

nurse, recreation worker, and house parent work together to help the dependent child to become independent, and the neglected child to achieve security. The various professions may all be included within the institution's staff, but often, and to the child's advantage, professional workers in a nearby community are members of this team. The use of neighborhood and community facilities helps to offset the regimenting influences of institutional life.

Institutional care for infants and preschool children has been severely criticized because young children need more affection and individual attention than can be supplied in most institutional environments. Some children of school age also require more love and attention than it is practical to provide in an institution. This is true even of some adolescents, but there is more value in group life for them than for younger children. After puberty children are more gregarious than at earlier ages, and the natural revolt of adolescents against adult authority in the home makes life in an institution or boarding school practical for many of them.

Modification of congregate care has been made possible by the reduction of the population of many institutions, a change which in turn has permitted the reduction of the size of dormitory groups. It was not uncommon in 1951 to find a unit of 10 or 15 children under one housemother in a room or suite of rooms previously crowded with 25 or 30 children. This change was made possible partly by improved social service, whereby the average length of institutional residence was greatly reduced, sometimes to less than half what it had been a few years before. Under such conditions many of the advantages of small cottage units could be realized. But the more usual situation was the overloading of workers with groups of children so large as to make regimentation unavoidable.

The development of small cottages has permitted a type of institutional care previously impractical. The freedom from restraints in a cottage of 10 or 12 can be approximately the same as children enjoy in family homes. Such a cottage usually is a complete living unit for children and house parents, with kitchen, dining room, living room, playroom, sewing room, storage spaces, sleeping quarters, and bathrooms. Some cottages have individual bedrooms for a few children, and the dormitories in small cottages seldom contain more than three or four beds.

The creation of cottage life and the greater freedom in the lives of the children call for house parents more capable than the matrons and attendants who formerly regimented boys and girls in congregate dining rooms and dormitories. Most institutions seek as house parents workers with education and such interest in their work as will qualify them for the study of child development and other subjects included in staff training classes. House parents are expected to cooperate with social workers, nurses, psychiatrists, and others who are working intensively with particular children. A cottage may have only a housemother, but there is a tendency to employ a married couple so that the children may have the influence of both sexes, as in a family home.

Delinquent Children.—Nearly all delinquent children for whom courts decide there should be care outside their own homes are committed to training schools, two thirds of which are under

government auspices. Detention homes, usually operated by county or municipal juvenile courts, play an important role in the care of children alleged to be delinquent, before and after their appearance in court and pending their admission to training schools. The detention of juveniles increasingly is provided in subsidized foster homes, a practical arrangement in thinly populated communities where an institutional detention facility may be unoccupied for periods of weeks or even months. Too often, however, children are detained in jails, sometimes without segregation from adult prisoners.

Even a few days in a substandard detention home often leaves a child shocked and embittered. This is true of those who continue on their way to a state training school for delinquents as well as of those who are returned to their own homes. Sometimes a child held as a material witness, as in cases where he or she has been the victim of a vicious attack by an adult, is compelled to live with delinquents in a detention home or jail. Studies made by the National Probation Association (now the National Probation and Parole Association) in 1945 described serious inadequacies in most detention facilities and indicated a lack of facilities in many communities. The association emphasized the need for a variety of facilities, including boarding homes or small home-like shelters for children who do not require security detention. For a rural county which cannot afford to construct and maintain a modern detention home it recommended cooperation with other counties in the operation of a regional home. Reduction in the length of detention through the prompt disposition of cases by courts is a common need. To spare children a detention experience is desirable whenever the situation warrants keeping the child at home or providing other types of care. In addition to custody, detention should provide medical, educational, recreational, and religious services and influences, in keeping with the best practices in child development and child care.

Training schools for delinquents have evolved from the houses of refuge established in Boston, New York, and Philadelphia in the 1820's, and from the reform schools which most of the populous states were operating by 1860. An unfortunate heritage is the congregate nature of most of the work. Although it obviously is more difficult to serve delinquent children effectively, the dormitory or cottage groups in training schools usually are larger than they are in institutions for dependent and neglected children. There is a marked tendency to reduce the size of school-room classes and work groups in training schools, but the congregate dormitory, sometimes a unit for 30 or 40 in one "cottage," has seldom been replaced. Mass treatment tends to provide training in vicious habits and preparation for crime more often than it produces the rehabilitation so badly needed by those who have become delinquent.

Few training schools operate on budgets large enough to permit the elimination of the overloading of workers and the mass care and training which still persist. Larger staffs and more capable workers are employed in states where the funds for the care and training of delinquents are most adequately provided. In 1951 it was apparent that if the training and treatment of juvenile delinquents was to become effective, the per capita cost would be nearly as great as the

cost for hospital services for medical and surgical patients. The greatest additional outlay needed in most institutions was for larger staffs, including highly qualified teachers, social workers, physicians, nurses, recreation leaders, and house parents. Many institutions in 1951 provided an unattractive and nutritionally inadequate diet, another condition due to limited budgets and poorly qualified staff. If mass care and treatment was to be eliminated, large amounts must be spent in replacing obsolete dormitories with cottages for as few as 10 or 15 children.

Training schools for delinquents are asked to serve boys and girls with whom homes, schools, churches, and social agencies have failed. Occasionally, a judge will commit a neglected or mentally deficient child to such an institution, a practice more common when the resources for serving handicapped children were less specialized. Most of those responsible for the commitment or admission of children to training schools are still inclined to be more concerned about the child's misbehavior than about his problems. Treatment and rehabilitation, however, are replacing the concepts of trade training and reformation which still characterize much of this work. In the states where the greatest progress has been made, there is a tendency to commit to training schools only the seriously delinquent. To allow further specialization, the state of New York in 1947 opened in Orange County its New Hampton Security Annex of the New York State Training Schools for Boys. There the two large and relatively open training schools sent their most highly disturbed boys, many of whom were chronic runaways and some of whom had committed holdups, stabbings, assaults, homicides, or sex offenses. This new institution, with a capacity of only 60 boys, has a staff ratio of more than one worker to two boys. There are three psychiatrists on the staff, each spending one day a week at the annex, each with no more than 20 boys to serve. Even though the boys live in cell-like rooms in one congregate building, the individual treatment thus provided has produced favorable results in most cases. In 1951 about one third of the boys went without an accompanying adult to work occasionally or regularly at agricultural or other employment outside the institution. Here, as in the best-staffed training schools, fear, repressions, and severe punishments are recognized as inadequate influences tending to aggravate the children's problems. Conscientious and consistent efforts are made under psychiatric guidance to develop confidence through the progressive use of freedom and the recognition of achievement.

Emotionally Disturbed Children.—Treatment centers for emotionally disturbed children have been developed under both government and private auspices. Some institutions have been founded for this purpose, and others previously caring for dependent, neglected, or delinquent children have developed treatment as a function, in some cases as their only function. The varying degrees of proficiency of those providing this service, and the different psychological approaches to the treatment of behavior, make it difficult to classify such institutions except in cases where they restrict their work to treatment and have a professional staff sufficient to sustain such treatment.

Well-known institutions for dependent and neglected children which have become treatment

centers for the emotionally disturbed are Bellefaire, Cleveland, Ohio; Ryther Child Center, Seattle, Wash.; and St. Christopher's School, Dobbs Ferry, N. Y. Outstanding among the training schools for delinquents which have adapted their functions to provide psychiatric treatment is the Hawthorne-Cedar Knolls School, Hawthorne, N. Y. These four institutions serve boys and girls, a distinct advantage in view of the monastic traditions which in most institutions for delinquents, and in many of those for dependent and neglected children, have imposed separation of the sexes.

The use of the group in psychotherapy in such centers has been studied and applied to the extent that other institutions, especially training schools for delinquents, are recognizing values in group care which traditionally have been ignored. The treatment of many of the emotionally disturbed includes a phase of study, either at the treatment center or before admission, and placement with relatives or in foster homes as treatment progresses and as the child is ready to maintain the relationships necessary in family life. Research on the development of study homes and residential treatment centers for such children had been completed or was in process in 1951 under various auspices. The Child Welfare League's two-year study, to be published in 1952, covered programs under the leadership of psychiatrists, social workers, and members of other professions.

Mentally Deficient Children.—The development of institutional facilities for mentally deficient children, dating from about 1850, lagged behind the establishment of institutions for juvenile delinquents. Almshouses, prisons, and mental hospitals continued even into the 20th century to serve as catchall shelters for many whose lack of training or inability to profit from training left them unable to compete with more intelligent children.

Even in 1951 the overcrowding in training schools for the mentally deficient was worse than in any other type of institution serving children. Most institutions then had beds in corridors, and in some the congestion was so great that many were required to sleep on floors. For the most part the facilities were congregate, with 60, 80, or more beds in each dormitory. One of the happy exceptions was the Southbury Training School, Southbury, Conn., an institution for about 1,400 on the cottage plan constructed in 1939-1940. There, only the idiots and imbeciles were in hospital-like units with congregate wards. The rest of the children and adults were in cottages for 18 or 36, each cottage with its own kitchen and dining room.

The training schools serving the state of New York operate, in addition to their large institutions, cottage colonies located in rural neighborhoods or in small cities. In these units, where 20 to 40 live apart from the rest of the institution, those nearly ready for discharge are trained. They are given household duties and work experiences resembling the responsibilities which they will carry after leaving the institution. The first extensive development of the colony system was made by the Rome State School, Rome, N. Y.

Early leaders in this field of service came from the professions of education and medicine, and through the years the administration of most training schools for the mentally deficient has been characterized by the teachings and terminology of either educators or physicians.

Dr. Walter E. Fernald, who in 1887 began his work at the Massachusetts State School for the Feeble-Minded, at Waverly (now the Walter E. Fernald State School, Waltham), continuing there until his death in 1924, was the pioneer physician whose leadership extended throughout the United States and to other countries. He organized the clinical study of the mentally deficient and developed criteria for the diagnosis of mental deficiency. A center of educational leadership in this work was developed after 1888 at the Training School, Vineland, N. J., where Edward R. Johnstone (from 1889) administered a service soon characterized by research and by a program of training for psychologists and educators. These leaders and their associates and successors have helped all those who serve effectively the mentally deficient to understand the various types of mental deficiency and factors contributing to this handicap, including heredity, injuries to brain tissues, and deficiencies in the development of the brain.

The mentally deficient are commonly divided into three groups: idiots, imbeciles, and morons. Many morons can be educated and trained so that they may adjust effectively in society and become useful workers in agriculture and industry. Idiots can do little or nothing to take care of even their elemental needs, such as feeding themselves; but efforts to train imbeciles have allowed many of them to perform simple tasks, attend to their personal wants, and observe elementary rules of hygiene. As skills in service to the mentally deficient increase, and as research progresses, there are fewer of the errors in diagnosis and classification which in the past led to the commitment to training schools of a few who needed remedial education or medical service—for example, some of those with cerebral palsy or epilepsy whose intelligence had been concealed by their handicap. The intelligence tests used in determining mental deficiency are considered valid for this purpose only when they are correlated with medical findings and social criteria.

Parents of mentally deficient children have organized for purposes of cooperation with those who serve their children. The National Association of Parents and Friends of Mentally Retarded Children is interested in child care and training both at home and in school. Several training schools for the mentally deficient have parent associations. See also CHILD LABOR; CHILD PSYCHOLOGY; CHILDREN, DISEASES OF; CHILDREN'S BUREAU; MENTAL RETARDATION; SOCIAL SECURITY; and separate articles on leading national organizations concerned with the welfare of children.

CHILDBIRTH. See OBSTETRICS.

CHILDE HAROLD'S PILGRIMAGE, a poem by George Gordon Byron (q.v.). Despite diversity of critical opinion and the fact that it has become hackneyed through use in guidebooks and school readers, *Childe Harold* still remains the most famous descriptive poem in English. It was written, says Byron, "as a mark of respect for what is venerable and of feeling for what is glorious." The poem is divided into four cantos aggregating 4,500 lines; its meter is the nine-line stanza of Edmund Spenser's *Facrie Queene*. Though usually termed a descriptive poem, *Childe Harold* is really a series of descriptive, reflective, and lyrical stanzas strung on a slender thread of narrative formed by the wanderings of its eponymous hero through the countries described. But Harold, who figures only slightly in the first three cantos, and who disappears entirely in the fourth, was, in spite of Byron's strenuous denial, never other than the poet himself.

Byron's travels through Portugal, Spain, Albania, and Greece in 1809 and 1810 furnish the subject matter for cantos 1 and 2, which, upon their publication in 1812, caused their author to exclaim, "I awoke one morning and found myself famous." Their popularity, such as few poems have ever attained, was due largely to their posing, their showy rhetoric, and their satire, which exactly suited the taste of the age. Except for the fine stanzas on Greece (canto 2, stanzas 73-90), however, they contain little of value. But the third and fourth cantos, published in 1816 and 1818, respectively, belong to a higher order. His earlier poses and affectations are now laid aside, and his style is direct and mature. Canto 3 is devoted to Waterloo, the Rhine, and Switzerland; canto 4, to Italy; with their landscapes, historical associations, great men and great events, cities, buildings, and works of art. But not one half of the matter is descriptive, for the poet usually passes into reflection, and from this into the purely lyrical. In Italy his wanderings are easily traced, from Venice through Ferrara and Florence southward to Rome, but *Childe Harold* is far from being a guidebook. Byron selects only what arouses his emotions, and presents objects only as colored and interpreted by his own personality. Yet so essentially just and adequate are many of his descriptions, such as those of Venice, Rome, the Pantheon, and the gladiator, that they have become identified with the objects they describe. The contemporary popularity of *Childe Harold*, however, was not due solely to the splendor and energy of these descriptive passages. The spirit of the age spoke in its pleas for justice and liberty, and for social, political, and religious reform; and contemporary interest was quickened by the reflections on the French Revolution and Napoleon, and by political allusions and prophe-

cies. Added to all this was the daring revelation of the poet's own complex and brilliant personality.

Despite the diversity of critical opinion, it may safely be said that *Childe Harold* contains much poetry of a high order, particularly passages on the Rhine (canto 3, stanzas 50-56); on night and storm on Lake Geneva (3, 85-97); on the marble cascade (4, 69-72); on the ocean (4, 178-184). Again, Byron's historic imagination can summon "the glory that was Greece, the grandeur that was Rome," and make the reader feel the desolation of once great and now fallen states: on Athens (canto 2, stanzas 73-90); on Venice (4, 1-19); on Rome (4, 78-82). With all its lapses into empty rhetoric, its moral platitudes, its ostentatious parade of the poet's "bleeding heart," *Childe Harold* still possesses, as Algernon Swinburne said, "the splendid and imperishable excellence of sincerity and strength."

MARION TUCKER.

CHILDE ROLAND TO THE DARK TOWER CAME, a poem by Robert Browning.

One of the most powerful and impressive of Browning's shorter poems, *Childe Roland* is a narrative monologue in which "Childe" (meaning young lord) Roland, a medieval knight, tells the story of his quest of the "dark tower," though to whom he speaks, and when, and where, we never know. The poem, which is in 34 six-line stanzas, was written in one day, Jan. 3, 1852, in Paris, and was first published in the volume entitled *Men and Women* in 1855. Its title was suggested by a single disconnected line spoken by Edgar in *King Lear*: "Child Rowland to the dark tower came" (Act 1, scene 4, l. 187). Its grotesque imagery is perhaps to be understood only in the light of the unreal and fantastic world of Edgar's fancy. The strangely impressive setting presents a series of pictures as by Albrecht Dürer, in turn terrific and grotesque, fantastic in the general impression but sharply realistic in detail. In spite of Browning's assurance that the poem is "only a fantasy," commentators have offered various interpretations of its supposed allegory, not one of which is without inconsistencies. Probably the poem is best taken simply as an effort of the imagination from which each reader may gain what he will. Possibly a broad and safe interpretation is that *Childe Roland's* quest is the journey of life, with its dangers, failures, and successes, its pursuit of an ideal through perils both real and imaginary, and its final triumph through sheer power of will. The climax of the poem is superb in the crashing finality of its long-drawn trumpet blast, defying fate and all unseen malignant forces, and claiming victory even in the midst of apparent defeat.

MARION TUCKER.

CHILDEBERT, chîl'dé-bêrt, Fr. shêl-dé-bâr', the name of three Frankish kings of the Merovingian dynasty.

CHILDEBERT I (c.495-558) succeeded to the kingdom of Paris in 511 on the death of his father, Clovis I. When his brother Clodomir, king of Orléans, died in 524, Childebert and a third brother, Clotaire I, king of Soissons, killed Clodomir's two eldest sons and seized his dominions.

CHILDEBERT II (570?-596) was proclaimed king of Austrasia in 575 on the death of his father, Sigebert I. In 592, on the death of his

uncle, Guntran, he also succeeded to the kingdoms of Burgundy and Orléans and to part of Paris. CHILDEBERT III (c.683-711) was proclaimed king of Austrasia and Neustria in 695 on the death of his brother, Clovis III. He was king in name only, however, real power being exercised by the mayor of the palace, Pepin of Herstal.

CHILDERIC, *chīl'dēr-ik*, Fr. *shēl-dā-rēk'*, the name of three Frankish kings of the Merovingian dynasty.

CHILDERIC I (437?-481) became king of the Salian Franks about 458. As an ally of Rome he fought the Visigoths in 463, and later waged war on the Saxons. His capital was at Tournai, where his tomb, containing numerous examples of Merovingian art, was discovered in 1653.

CHILDERIC II (c.653-673) in 660 became king of Austrasia; in 670, on the death of Clotaire III, he also succeeded to the throne of Neustria and Burgundy. Three years later he was murdered.

CHILDERIC III (c.714-751), the last Merovingian ruler, was recognized as king of Austrasia and Neustria in 741 by Carloman and Pepin the Short. He never exercised any real power, however, and in 751 he was dethroned.

CHILDERMAS DAY. See INNOCENTS, FEAST OF HOLY.

CHILDREN, Diseases of. Any consideration of children's diseases or, more properly, the diseases of infancy and childhood, should take into account the normal development of the average child. At birth infants weigh about 7½ pounds and are about 21½ inches tall. After a year the weight has usually increased to a little over 21 pounds and the height to about 2½ feet. At 10 years of age most children will weigh about 67 pounds and should be more than 4 feet tall. In normal children the first dentition occurs at 6 months and the closure of the anterior fontanel comes at 18 months. At birth the circumference of a child's head should measure about 13½ inches, which will increase to about 21 inches at 12 years of age. Children may be tall for their age or too short, but this of itself does not indicate disease. Diseases to which children are subject may be divided into at least three groups: (1) diseases which are antenatal or occur in connection with childbirth; (2) diseases peculiar to various epochs in the life of the child; (3) diseases common to adults and children.

Prematurity and Developmental Defects.—A premature infant is one born before the 38th week of intrauterine life. An infant born before the 34th week is not likely to survive. About two per cent of all infants born are premature, and most of them weigh less than 5 pounds. The greater part of the deaths among these infants is due to intracranial hemorrhage. After 48 hours the chance of survival becomes much improved.

Developmental defects during intrauterine life are of two classes, mechanical and chemical. Among mechanical defects are conditions which are usually obvious to the mother and are referred to generally, as deformities. Omitting the class of cases including monsters and joined twins, the deformities most often seen at birth are: lack of symmetry of head and face, harelip and cleft palate, stiffness of joints, wryneck, and clubfoot. The chemical disturbances are usually: lack of minerals in the body, blood dyscrasia, tetany, and endocrine disturbances.

At the moment of birth full expansion of the lungs may fail to take place and what is known as asphyxia neonatorum, associated with cyanosis, may be observed. This is overcome, as a rule, by removal of the cause of the obstruction in the trachea or larynx, by artificial respiration, and by other simple means. If due to a developmental defect of the heart or great vessels (patent foramen ovale, blue baby), mechanical means will be of no avail.

Obstetrical injuries, resulting from such factors as accident, undue use of force, the employment of forceps in delivery, are of frequent occurrence. Among them are hematoma of the scalp, which is not often a serious matter, since it is resolved quickly, and intracranial hemorrhage, which may give rise to grave and unfortunate sequelae, including permanent mental impairment, spastic paralysis, or athetosis. Facial palsy from mechanical injury is usually one-sided and is readily recognized. It is not as serious as it appears, since recovery takes place, as a rule, in two to three weeks. Complete paralysis of the arm attracts attention at once, since the arm hangs limp, but this should not be confused with fracture of the arm or clavicles. It is caused by traction upon the arm in difficult deliveries, which injures the brachial plexus and results in either a temporary or a permanent paralysis.

Pyogenic infections of the newborn infant frequently are encountered, because the child possesses little immunity. The umbilicus is the site most often involved, and what begins as a mild irritation may spread to become an uncontrolled case of sepsis or erysipelas, ending in death. Other parts of the skin are also subject to infections such as impetigo and pemphigus, indicated by large watery or purulent blotches and due to a staphylococcus infection. Such ailments, which would appear to be of little danger to an adult, may threaten the life of a weak and poorly nourished infant; statistics indicate a high mortality among all infants considered as a group.

Jaundice of the newborn may be simple, infectious, or a variety known as icterus gravis. The simple form is rectified in two weeks at most. Infectious jaundice is sometimes associated with a skin or umbilical infection. Icterus gravis is familial. As time passes, the jaundice increases, the color of the skin deepens, and the picture of hemolytic anemia is present. Blood transfusions have been reported as successful, if the blood is suitable, that is, if it is not destroyed by antibodies from the mother and present in the infant's circulation.

Other infections of the newborn are ophthalmia, now becoming rare through efficient prophylaxis, and hemorrhage from the umbilicus or gastrointestinal tract. This last may accompany an infectious diarrhea of young infants, caused by contact with an adult carrier, the agent being salmonella or a virus. It is said to be present in about 15 per cent of all infants.

Other diseases, not always classed as infectious, are rather conditions due to some physical cause, such as dehydration, ileus, intussusception, and interference with urinary output.

Diseases of nutrition are very frequent in the early weeks of life. Vomiting is the commonest and perhaps the most frequent symptom of many disorders. It may indicate overdistension, improper feeding formulas, especially those with excess fats, obstruction of the pyloric opening of the stomach, intestinal obstruction, or the begin-

ning of some infectious disease. Diarrhea is quite common among artificially fed infants. The stools are good indicators of the cause. If vomiting and diarrhea continue too long, acidosis may result.

Among the causes of infant morbidity the lack of vitamins holds a high place. These conditions have both specific and general symptoms. If due to lack of vitamin A (avitaminosis A), beside dryness and scaliness of the skin, night blindness may be present. If from lack of vitamin B (thiamin) the symptoms noted may be meningeal, with convulsions, or there may be manifestation of polyneuritis (beriberi). Lack of vitamin C leads to scurvy, while, if nicotinic acid is not present in the diet, a dermatitis, associated with sore tongue and general malaise, may be observed (pellagra). Lack of riboflavin produces a stomatitis with loss of weight. Loss of vitamin D affects metabolism, especially calcium and phosphorus, and causes bone changes (rickets). Lack of calcium also is responsible for the appearance of tetany and osteomalacia. All these manifestations can be prevented, if the child receives proper amounts of cod-liver oil, thiamin, fruit juices, ascorbic acid, vitamin D, nicotinic acid, calcium, and sunlight. What cannot be supplied from the diet must be given in food or in glucose solutions. In all cases of apparent malnutrition a 10 per cent decrease from the normal standard of height and weight should be a dependable guide when associated with flabby muscles, pallor, nervousness, and digestive disturbances. If these conditions are present, a search should be made for the cause, and the absence of at least some of the vitamins should be assumed.

Digestive Disorders.—The cause of digestive disorders should not be confused with manifestations of disease. These conditions may be induced by underfeeding (either too small an amount or too poor a quality of food) or by overfeeding. Indigestion from protein foods is not usually an important cause, since both carbohydrate indigestion, and especially that due to an excess of fat, are much more frequent. Stomatitis, or inflammation of the mouth, may arise from chemicals or from extreme heat, or may be due to a virus infection. If ulcerative in character, this may be a specific infection. Gangrenous stomatitis (noma) is seen in extremely debilitated children and may commence as a small slough, which spreads rapidly, sometimes destroying the greater part of one side of the face. Some cases of mouth inflammation are due to a parasitic fungus, *Oidium albicans* (thrush).

A child's teeth are subject to many malformations, including supernumerary teeth and total or partial absence of teeth. Defects in the enamel are frequent and may be marked by underdevelopment or by spotting. These defects may indicate a lack of calcium in the diet.

Children are especially liable to acute pharyngeal and tonsillar disease and to retropharyngeal and peritonsillar abscess, which may cause difficulty in breathing. Ludwig's angina is a serious purulent, and sometimes gangrenous, infection of the submaxillary area in the neck. Such ailments require surgical intervention, as a rule, and this should be rendered promptly, since they may threaten life. Occasionally is observed disease of the esophagus, which may be due to a fistulous connection with the trachea or a bronchus. Spasm of the esophagus is more common (cardiospasm) and may be marked by disturbing symp-

toms. Regurgitation of food with swallowing of the regurgitated material will suggest the diagnosis. Children often swallow corrosive poisons such as lye. If recovery occurs, an esophageal stricture may result, calling for early and continuous treatment by dilatation. A foreign body lodged in the esophagus, if it cannot be swallowed nor regurgitated, must be removed through the esophagoscope.

The stomach in children may be: (1) malformed, (2) associated with pyloric stenosis, (3) transposed with the viscera, (4) lodged in the thorax (due to diaphragmatic hernia, sometimes called "upside down stomach"), (5) the seat of tumor such as sarcoma. Projectile vomiting is a symptom of pyloric stenosis, while recurrent vomiting indicates a nervous reaction and may be due to extreme fatigue or excitement. Acute gastritis is not at all unusual in children and is commoner than in adults. Due usually to food or chemical poisoning, it may be associated with acute diarrhea. In improperly fed children chronic gastritis may develop, but this is unusual in older children. Gastric ulcer is rare in children of any age, but gastric hemorrhage is seen frequently and may proceed from a multitude of causes. Very young children often swallow foreign bodies, such as buttons, coins, nails, lead toys, and glass. Most of these pass from the stomach to the intestine within a few days at most. If a foreign body remains in the stomach more than a week or 10 days, it may require surgical removal.

Intestinal obstruction may arise from fecal impaction, malformations, and infections such as peritonitis. Telescoping of the intestine (intussusception) and twists of the intestine (volvulus) are fairly common in infants and have a high mortality.

Appendicitis is seen rarely in children under four years of age, but, if present in any child, should admit no delay in operation.

What is known as celiac disease is seen occasionally in children in the second and third year. It is a chronic intestinal complaint characterized by fatty stools having a foul odor.

Intestinal parasites are of frequent occurrence. These are generally pinworms, roundworms, and tapeworms. They are merely infestations and do not cause disease, but are accompanied by symptoms. The only serious infection by a parasite likely to be encountered is trichinosis, which is due to eating uncooked or insufficiently cooked pork. It is a dangerous and painful disease for which no cure has been found.

Dilatation of the colon (megacolon, Hirschsprung's disease) is a functional disorder with swelled abdomen, constipation, and colic. The bowels sometimes are not evacuated for more than a week, unless enemas are employed.

Rectal disease in children is usually due to anal atresia and anal occlusion. Passage of the feces is difficult in the former and in the latter is impossible without operation. In female children there is sometimes a passage from the rectum into the vagina. Such a condition can be cured only by a plastic operation. Prolapse of the rectum, in which the organ is inverted and protrudes, is usually controlled by replacement and by the use of nonsurgical measures.

Other digestive organs which are the seat of disease are the liver (cysts, abscess), the umbilicus (hernia), the gall bladder and its ducts (infectious jaundice), the peritoneum (peritonitis, ascites from tuberculosis), the groin (inguinal

hernia). In young infants a hernia sometimes will disappear, if a yarn truss, a spring truss, or an abdominal binder be used continuously for a considerable period. Diaphragmatic hernia has been mentioned under remarks concerning the stomach.

Diseases of Metabolism.—For the most part these are best regarded as disorders. Two common ailments of children are acidosis and alkalosis. Acidosis is a disturbance of the normal acid-base balance with excess acid in the blood. It produces dyspnea, asthma, drowsiness, and vomiting. Occasionally an attack may indicate the presence of diabetes, hitherto unsuspected. The symptoms of alkalosis are less pronounced, but extreme weakness and lethargy are present. Tetany is sometimes observed.

Cyclic vomiting is confined almost exclusively to the period of childhood and is apt to make its appearance before the age of two. It runs in families and is seen generally in nervous, high-strung individuals. The attack appears suddenly with incessant vomiting, drowsiness, high fever, and sometimes is followed by a period of coma. The condition may give rise to alarm, since it may continue for at least a week. Little is known of the cause, but the attacks disappear usually as the age of adolescence approaches.

Diabetes mellitus is seldom present in the extremely young, but is of frequent occurrence in children five to ten years old. The onset is usually abrupt, much more so than in adults, and extreme thirst and enuresis (bed-wetting) developing within a week or two should arouse suspicion. The most important complication of diabetes in children is coma, which may be an early symptom. Other complications of the disease, so often encountered in adults, are generally absent. The outlook for recovery, before the discovery of insulin, was practically hopeless and life was seldom prolonged for more than three or four years. At present the prognosis is as good as in adults. Diabetic children require insulin in practically all cases.

Other metabolic disturbances due to an abnormality in chemical function of the body are: albinism, urinary disorder (such as cystinuria), and lipid deposits in various portions of the body (Gaucher's disease, Niemann-Pick disease).

What is called the Schüller-Christian syndrome also occurs in children up to eight years of age. This is a necrotic bone disease of the skull, the larger flat bones, and sometimes the long bones, with accompanying diabetes insipidus.

Diseases of the Urogenital System.—Diseases of the urinary tract differ little from those affecting adults; but, since the symptoms are often less easily interpreted, urinary examinations are of great importance.

Albuminuria, in the presence of high fever due to respiratory disease, is quite common and does not necessarily indicate any serious damage to the kidney. That associated with scarlet fever may indicate a nephritis. Sometimes a persistent albuminuria may prove to be merely functional and disappears in time.

The various types of renal disease seen in children are much the same as those found in adults. (See KIDNEY.) Tumor of the kidney or adrenals is often sarcoma or lymphosarcoma and may exist in newborn infants. Surgical removal is sometimes successful.

Bladder and genital malformations are occasionally observed. Exstrophy of the bladder

(externally situated bladder), defects of the urethra (hypospadias and epispadias), undescended testicle and hermaphroditism in males, atresia of the vulva and imperforate hymen in females are the commonest developmental defects. Girls are especially liable to nonspecific vaginitis or to epidemic gonococcus vaginitis.

Respiratory Disorders.—Nosebleed is of common occurrence in children, but is seen seldom in infants. It may mark the onset of infectious disease.

Acute rhinitis is present in children in much the same form as in adults. Allergic rhinitis (hay fever) is sometimes continuous instead of seasonal and may be due to various irritating substances other than the pollens.

Otitis media (middle ear disease) is a complaint to which children are particularly prone and in young infants sometimes will be suggested by the symptoms of rolling of the head and of putting the hands to the head, in cases of those too young to talk. Mastoid disease is now seldom seen in otitis media properly treated.

Croup is a term used to designate the choking spasm observed in young children with acute laryngitis, laryngeal stridor, and laryngeal spasm, occasionally in diphtheria.

Acute bronchitis is particularly common in younger children and, while it may resolve itself in a week, the disease may continue into bronchopneumonia in the feeble and undernourished, who have a poor outlook for recovery. Chronic bronchitis is seen oftener than is generally supposed and may be due to untreated tonsillar infection or to adenoids. It is apt to be worse in winter.

Foreign bodies lodged in the bronchi frequently are reported and often are in the news, since their removal is now achieved by the use of the bronchoscope. They are evacuated by coughing in only a small percentage of cases (from 4 to 5 per cent).

Asthma in children may be due to allergy or may be associated with other diseases.

Lobar pneumonia is common to all ages. It has a sudden onset, frequently with vomiting, and is occasionally confused with appendicitis. Clinically it does not differ from the disease present in older persons. A frequent complication is empyema or pus in the pleural cavity. The mortality in pneumonia under modern methods of treatment is probably not over 5 per cent in children.

Tuberculosis of the chest may be intrathoracic and may involve the mediastinal glands only. In children the disease has infinite variety and should be considered as an infection of a general and not a selective character. The cause is in the tubercle bacillus, which may involve any part of the body. Ordinarily the avenue of infection is the respiratory tract, but the bovine type may be acquired through ingesting milk from infected animals, which leads usually to abdominal tuberculosis. Recovery from this type is frequent. Contact with tuberculous adults is generally the manner in which children acquire the disease. In addition to the disease seen in the respiratory organs and in the peritoneal cavity, miliary tuberculosis, an acute variety, occurs. In obscure cases tuberculosis is sometimes difficult of diagnosis. X-ray films of the chest are of great value in detecting early cases.

Heart Disease.—Congenital disease of the heart is generally evident soon after birth and this variety accounts for about 2 per cent of all

cases of heart disease in children. In the more serious cases many infants die soon after birth. Causes include narrowing of the aorta or of the pulmonary artery and defects of the heart wall (open foramen).

Functional heart disturbances occur in children as in adults. These are principally: fatigue syndrome, arrhythmia, rapid heart, slow heart, flutter, fibrillation, and heart block.

Of the infectious diseases of the heart in children, rheumatic heart disease is one of the commonest and most serious. The term rheumatic is not strictly accurate, but is used to cover a multitude of symptoms and evidences of disease, such as neuralgias, sciaticas, back and joint aches, and generalized bodily and muscle pains seen in childhood. The rheumatic heart is rare before the age of 5 and becomes less common after the age of 10. Many of these cases are associated with tonsillitis and with recurring acute attacks of sore throat. There are intervals when the child appears well and at first the heart lesion may be overlooked entirely.

Heart disease is also associated with polyarthritis and chorea. The causal agent may be a variety of the streptococcus, but this cannot always be demonstrated.

The symptoms of cardiac disease are apt to be vague, but loss of weight, pallor, anemia, and breathlessness may arouse suspicion and lead to an examination of the heart. After an acute attack the heart may become normal, if no further symptoms appear and the cause is perhaps removed; or it may be permanently damaged, leading to valvular incompetency in later life. The outlook is by no means entirely bad.

Diseases of the Blood.—Nutritional anemia, in which the hemoglobin is as low as 30 per cent, is sometimes seen. This is due to lack of iron plus a lack of vitamin content in the food, which is manifested by rickets. Scurvy (avitaminosis C) is also accompanied by anemia. Aplastic anemia with a low red cell count may be due to acute or chronic infectious disease. The cause is often undetermined and the prognosis generally is unfavorable. Other anemias, seen also in adults, are Mediterranean (Cooley's), and a familial hemolytic variety known as sickle cell anemia. Many anemias in children are secondary to some acute or chronic disease or intoxication. Among these are diphtheria, pyelitis, and rheumatism. A frequent cause of anemia is hemorrhage, such as that following a tonsillectomy, or from hemophilia or purpura. Leukemia may be seen at any age and is not a rarity. Hemophilia is a hereditary disorder associated with prolonged bleeding from even a slight wound. The disease is manifested only in males, but is transmitted in the female line. Purpura is a condition in which spontaneous hemorrhages occur in the skin and in mucous membranes. It is usually a symptom of some disturbance of body chemistry and is observed in toxemia, anemia, or allergy. Some varieties bear the names of individuals who have brought them into special notice (Henoch's purpura). Hodgkin's disease in children is no different from that seen in adults.

Diseases of the Endocrine System.—See ENDOCRINE GLANDS; ADRENALS; CRETINISM; GOITER; MYXEDEMA; PITUITARY BODY; THYROID GLAND.

Diseases of the Bones, Muscles, and Joints; Locomotor System.—In children the differentiation of what are often called growing pains from

muscle and joint affections is not always appreciated. Some of these are due to changes in climate, others are fatigue pains, while still others indicate definite disease. In children over three years, if the pains in the limbs are accompanied by fever, if the joints are tender, or if the skin over these is reddened, the diagnosis of rheumatic fever should be suspected. Occasionally a case of acute osteomyelitis will be confused with rheumatism, but here the symptoms are usually localized in or about one joint.

Rheumatoid arthritis in children is not as common as in adults, but, if present, is manifested by great distortion of the joints of the hands and feet.

Achondroplasia is a joint disease in which shortening of the limbs and stubbiness of fingers and toes is pronounced. It has the appearance of dwarfism. The head is usually enlarged.

Other diseases of the same nature are fragile-bone disease, marble-bone disease, spider fingers, and skull deformities.

Spinal curvature is usually a postural disease or is due to infantile paralysis.

Muscular defects, atrophy or dystrophy, are sometimes congenital. Wryneck generally is congenital and only occasionally is acquired.

Diseases of the Nervous System.—Various forms of meningitis, while infectious, find their place here. Infants are especially liable to a basal posterior meningitis, while the epidemic cerebrospinal variety affects older children. In many cases permanent injury to the nervous system occurs, in some cases recovery may result. Tuberculous meningitis is invariably fatal.

Hydrocephalus is an enlargement of the head accompanying excessive accumulation of cerebrospinal fluid within the skull. The diagnosis is usually obvious. Little success has been achieved in the treatment of this condition.

Brain tumors in children are no different in character from those found in the adult.

Spastic paraplegia is often caused by intracranial hemorrhage with serious damage to the brain cells.

Infantile paralysis is an acute infection of the brain and spinal cord due to a virus, as yet unseen. It attacks children from the second to the sixth year most frequently. (See POLIOMYELITIS.)

Chorea, or St. Vitus's dance is characterized by involuntary movements and emotional disturbance. It is seen generally in children over five years old and its pathology is uncertain. The disease often is accompanied by heart disease. Recovery from chorea is the rule.

There are a number of other diseases of the nervous system which are organic, such as cerebral degeneration, various forms of ataxia (staggering), and a few diseases of the muscles, details of which are omitted here.

Infectious Diseases.—While children may be affected by almost all diseases encountered in adults, there are a few which deserve special mention, if only as reminders of their frequency among the young.

Diphtheria is still a serious disease of children, especially in isolated localities. It is essentially a disease of the young, is diagnosed bacteriologically, and is treated successfully by antitoxin. Nevertheless, it still enjoys a high mortality rate in some areas.

Scarlet fever is a local throat infection with severe toxic effects on the body. It is caused by

the *Streptococcus scarlatinae*. Its virulence has declined in the 20th century due to a number of factors.

Measles is one of the most infectious of the exanthemata and is due to a virus. It is common between the ages of two and seven and in some epidemics it runs rampant through a community.

Whooping cough is almost entirely a disease of childhood and the diagnosis is easily made. It has serious lung complications and may end in bronchopneumonia and death, in very young and weakened children. It runs a long course in the average case and is not to be considered lightly.

Chicken pox is a mild disease usually, but has been mistaken for smallpox.

Smallpox occurs in a severe (hemorrhagic) and in a mild form. In the 20th century it is found only in sporadic form in the United States and in countries where compulsory vaccination is not in force.

Mumps is seen frequently in children and is regarded generally as a children's disease, but is not at all infrequent in adults. It has a long incubation period and is sometimes undetected at first, because the characteristic symptoms may not be manifested always in the region of the parotid gland. It may have complications, especially in the testicle.

Typhoid and paratyphoid fevers, once common in children and an important factor in mortality, are now much less frequent due to improved public health inspections of food and water supply and to antityphoid vaccination.

Tetanus, rabies, and brucellosis (undulant fever) are diseases to which children are sometimes exposed.

Syphilis in children is generally the result of infection before birth. Such cases do not exhibit the primary stage and manifest the disease in full-blown form.

Diseases of the Skin.—Only the common diseases of the skin are mentioned here.

Perhaps the most troublesome is eczema, a dermatitis of infectious or noninfectious origin. The ailment appears usually after the third month. At first the rash is only a redness of the skin, but later it becomes a generalized patchy eruption with intense itching. Secondary infection of the skin is the rule and in neglected cases the body is covered with pustules, scales, and cracks. It is often resistant to treatment.

Nettle rash or hives (urticaria) is common and may be due to digestive disturbance or allergy.

Psoriasis is seen generally in older children and is a chronic, nonitching disease occurring in patches. The patches are scaly and the skin somewhat thickened. The cause is unknown and the psoriasis may persist at intervals through life.

Impetigo is a contagious skin disease of the streptococcal or staphylococcal origin, difficult of treatment.

Herpes of the lips and other parts of the body is common and may exist as herpes zoster (shingles).

Dermatophytoses, scabies, ringworm, and warts are particularly common. Warts are not contagious.

Miscellaneous Diseases and Common Conditions.—Children have a much less stable nervous system than that of adults. Consequently a great many behaviorisms exist. The nervous energy of a young child is out of all proportion

to its size and, if it finds no proper and legitimate outlet, will be thrown out of balance, so to speak. The result is the development of many abnormalities of conduct. Uncorrected actions become fixed habits. Moreover, the sense of fear existing in the minds of many children may have unfortunate manifestations. Among the many functional nervous disorders, all of which are characterized by one or more prominent symptoms, usually obvious, are the following.

Rolling the head and banging the head are two rather similar habits exhibited in young infants. There is no evidence that the child derives any pleasure by it and in many cases it causes pain and sometimes bruising. It is sometimes caused by teething or by earache, but more often there is no assignable cause.

Thumb-sucking is almost universal and thumb- or finger-sucking may persist for several years, if the habit is not broken. There is no evidence that this habit produces any appreciable change in tooth development.

Head-nodding is a rare condition, often associated with nystagmus of the eyes, and recovery from it usually is made in a few weeks.

Refusal of food in young children and habits of slow eating in older ones are annoying to parents, who are sometimes even alarmed over it. These peculiarities result from faulty management in early life. If parents or others show anxiety or irritation, refusal to eat normally may be persistent because of the notice which it receives, and this in turn fosters the child's egoism. Attempts to placate the child by offering other and more palatable food are worse than useless as corrective measures.

Holding food in the mouth (and refusal to swallow it) or expectorating food are also irritating habits, generally susceptible of correction by good management.

Nervous starvation is more serious, is seen in older children, who refuse to eat, and may be attended by great loss of weight. This is actually a psychosis and may be difficult to treat successfully.

Biting the nails is an unpleasant habit observed in nervous children and often is induced by observing adults who have never outgrown it. If it is allowed to persist, it will pose a difficult problem later in life.

Dirt eating (pica) is not common and is due to a morbid craving for articles like hair, paper, earth, coal. It causes chronic indigestion and foul stools, and the child is apt to exhibit nervous fits and outbursts of temper.

Disturbances of sleep, refusal to go to sleep or to stay in bed, and occasionally sleepwalking are among the common problems which confront the average parent. Underfeeding, overfeeding, and indigestion are basic causes. Bad or irregular sleeping habits and fear of the dark play their part. Rather common in younger children is nightmare (night terror), which not infrequently is due to some disturbing factor of the day, for the child lives over the incident in distorted form. True sleepwalking (somnambulism) is somewhat rare.

Delay in talking is a speech disorder, which worries parents who sometimes fear that their child is mentally deficient. This may be of no moment, but it may also be due to deafness, especially partial deafness. If entirely deaf, the child will of course be a mute. Mental retardation is also the cause in some cases.

Stuttering is an incoordination of the muscles used in speech. It is more frequent in boys than in girls and is made worse by nervousness and by mimicry on the part of other children. If it cannot be overcome by educational methods, it may persist through life.

Habit spasm is a disorder often encountered. It may take such forms as blinking, grimacing, head tossing, or aimless movements of the arm. It may last for months or even years, or it may become permanent. Curiously, if one habit spasm is overcome, another may take its place. The habit spasm of adults, though generally thought to be organic, is actually the persistence of a purposeless movement begun in childhood.

Bed wetting (enuresis) is almost universal and is a cause of much worry to parents. It is generally confined to the hours of sleep. Bed wetting should not normally continue much after the age of two, but no set age for it to cease can be determined. A variety of causes besides the continuance of the normal incontinence of infants may cause bed wetting. Certain diseases are sometimes responsible, and if persistent efforts do not eliminate the habit, a careful physical examination is indicated. In this connection it should be mentioned that many parents consider bed wetting in children up to the age of five a normal situation, which is far from true.

Incontinence of the bowels may indicate mental disorder or an organic disease. It occurs generally during the day. Sometimes it is due to mismanagement, but if it does not cease, the cause should be ascertained and medical advice sought.

Other disturbances pertaining especially to children are tongue-tie, which is not particularly common, and minor illnesses and fever associated with teething.

Convulsions may occur at any age, but are more frequent in young infants than in older children. They may indicate disease but are themselves a group of symptoms. Sometimes they are due to a true epilepsy which has now become manifest, but in the great majority of cases they arise from some other cause. Onset is abrupt, the eyes close, the limbs twitch, the tongue may be bitten, evacuation of the bowels may occur, consciousness is lost, and the child does not cry. In some cases convulsions are an indication of mental deterioration or intracranial disease. Death seldom occurs in the acute attack. The usual domestic remedy is immersion in a tub of warm water until a physician can be summoned. Crying convulsions sometimes are mistaken for true convulsive seizures, although the two are dissimilar. The former occurs after a fit of temper: the child holds his breath until cyanosis is apparent and asphyxia begins, after which he takes a full breath and, obtaining relief, becomes quiet. Spoiled children frequently indulge in this sort of fit. The disturbance may recur at intervals, but it disappears when the child is older.

Vulvovaginitis of young girls is not uncommon and is apt to be horrifying to parents. Lack of cleanliness may be the cause and the trouble may be rectified within a few days by the use of simple measures. In all purulent cases, however, a bacteriological examination is indicated to ascertain whether the gonococcus is present. If so, the disease may be due to contact with infected agents, such as adults, linen, or towels.

The disease is highly infectious and prompt treatment with penicillin is mandatory.

Phimosis, or narrowing of the prepuce, is common in male infants. It seldom interferes with the passage of urine, but it may cause irritation from lack of cleanliness. Circumcision is advised by many obstetricians as a routine practice.

Miscellaneous Emergencies Affecting Children.—In infants and in young children many conditions arise which are alarming to parents. Some of these are of no great consequence, while others are of serious import. In the case of a very young child, who cannot evaluate or describe his symptoms, it may be necessary to make a tentative diagnosis by observation. Moreover, the mother may often furnish information of value to the physician which he may not be able to obtain himself.

A few fundamental facts are of importance in examining the physical and mental condition of children. These include the following: A very sick child is generally listless and does not resist handling nor does he scream. If he lies in a peculiar position, this is because he finds it more comfortable to do so. If he does not move a limb freely, there is probably something the matter with it. If he vomits, the cause may be not something he has eaten, but the onset of some acute febrile disease. If he limps, a disease of the hip, knee, or leg bones may be responsible. If he puts his hand to his head, this may be a sign of middle-ear inflammation. Such examples can be multiplied many times. The most important thing for the physician to know is: What does the child do that he did not do formerly and what does he fail to do that he is used to doing?

Among acute emergencies affecting young children which must be dealt with without delay are pyloric stenosis, swallowed foreign bodies, convulsions, intestinal obstruction, obstruction of the larynx caused by inhaled foreign bodies, rectal obstruction and anal obstruction caused by impacted feces, and fractures. Some of these emergencies can be handled on the spot by using simple remedial action; others may require surgical intervention.

Other disorders which parents may note by continuous observation are epilepsy, the presence of intestinal parasites, congenital dislocation of the hip, muscular dystrophies, tuberculosis of the spine, lateral curvature of the spine, and tuberculosis of the hip or knee joint.

Even physicians may miss osteomyelitis of a leg bone and instead make a diagnosis of rheumatism. As a rule, such a diagnosis should not be regarded as final until the presence of an infectious bone or joint disease can be ruled out. Chronic pain in the knee or hip with spasm of the muscles will suggest tuberculosis of the joint involved. Fractures in children following a fall are sometimes overlooked. An injury to the elbow, for example, may be regarded as a sprain when it is in reality a condylar fracture. Any deformity or undue swelling of the arm, wrist, elbow, or other bony structure following violence should warrant a provisional diagnosis of fracture, which in children is often incomplete (greenstick fracture).

Intestinal obstruction is a serious emergency in young children. The outstanding symptoms are abdominal pain; vomiting; a swollen, drum-like abdomen; and, sometimes, the appearance of

a localized abdominal tumor. Impacted feces will cause symptoms of mild obstruction, but this condition can be relieved by administering an enema, or by the manual removal of the ball of feces, a procedure which will usually require brief etherization.

The accidental inhalation of a foreign body, such as an orange seed, which may be sucked into the larynx, can generally be relieved by holding the child upside down by the legs and slapping his back. If action is delayed and the foreign body is taken into a bronchus, surgical removal may be required. Swallowed foreign bodies should not cause immediate alarm, since they are generally expelled through the intestinal canal within a few days. If any doubt exists as to their whereabouts, X-rays will be required.

Convulsions and croup may cause some alarm. Children almost never strangle from croupous attacks, and simple remedies will suffice. Convulsions may have an underlying cause, such as epilepsy, but the simple convulsions of infancy will usually yield to a hot bath until such time as a physician can be summoned. See also PEDIATRICS.

HAROLD WELLINGTON JONES, M.D.,
Editor, "Blakiston's New Gould Medical Dictionary."

CHILDREN IN THE WOOD, The (also called **THE BABES IN THE WOOD**), an old English ballad found in several collections, including Thomas Percy's *Reliques of Ancient English Poetry* (1765, q.v.). It tells the story of two children whom their uncle wished to murder for their inheritance. He hires two assassins, but one of them, rebelling at killing the children outright, leaves them to die in the woods. The authorship of the ballad is unknown, and the date is uncertain; it appears in the *Stationers' Register* of 1595, and was probably written at about that time. A play by Robert Farrington, published in 1601, has a similar plot, and some critics believe the source of the two to be the same.

CHILDREN OF EARTH, a play of New England life by the novelist Alice Brown (q.v.). In 1913 the theatrical producer Winthrop Ames offered a prize of \$10,000 for the best play by an American author. Manuscripts were to be submitted anonymously. The prize was awarded to Miss Brown for *Children of Earth*, and the play received its first production at the Booth Theatre, New York City, on Jan. 12, 1915. Although the critics hailed its literary and poetic qualities, the play failed of popular appeal. The heroine, who has led the life of a conventional New England spinster, experiences a great love in middle age. Her character and that of her lover are not fully developed, however, and when their New England consciences drive them back into conventionality, the spectator remains unconvinced of the logical reasons for their adventure.

CHILDREN OF GIBION, a novel by Sir Walter Besant (q.v.), published in 1886. It tells the story of two children brought up by a wealthy widow in the West End of London.

One is her own daughter; the other, the child of a slum family of the East End whom she has adopted. When the girls are grown up, they meet this family, and through the presentation of contrasting ways of life the author gives his views on social problems. The novel is well written, and it became very popular. It did much to call attention to the evils of sweatshops and also helped to further the movement to organize women workers in labor unions.

CHILDREN OF THE ABBEY, The, a romance in four volumes by the Irish novelist Regina Maria Roche (q.v.), published in 1798. It recounts the adventures of a motherless girl beset by enemies. Melodramatic and sentimental, the romance suited the taste of the times and became very popular.

CHILDREN OF THE GHETTO, a novel by the English writer Israel Zangwill (q.v.), published in 1892. It is divided into two parts. The first is a masterly account of life among poor Jews in London's East End and of their adherence to the tenets and practices of orthodox Judaism. The second describes those of the next generation who have acquired wealth, and their problems of adjustment to contemporary London life. The novel was dramatized in 1899. Zangwill's sympathetic and well-drawn picture of Jewish society helped to further the Zionist movement, in which he was interested.

CHILDREN OF THE NIGHT, The a collection of poems by Edwin Arlington Robinson (q.v.), published in 1897. It consists of 57 short poems, most of which are complex portraits of various individuals. Robinson's delineation of character is so well done that the reader feels that he knows the person described. Miniver Cheevy, who "loved the Medici," Richard Cory, and the rest are colored by the poet's pessimistic view of life. The poems are sometimes obscure because of their condensation, and the tone is sardonic. *The Children of the Night* was highly praised by Theodore Roosevelt, in the *Outlook*.

CHILDREN OF THE SOIL, a novel by Henryk Sienkiewicz (q.v.), published in Poland in 1894 as *Rodzina Polanieckich*. It tells the story of the marriage of Pan Stanislas Polanietzki and Maryina Plaritska, and of their problems, misunderstandings, and eventual happiness. The novel paints a broad picture of contemporary Polish life. Of particular interest are the glimpses of traditional Polish country life and the treatment of questions of property.

CHILDREN OF THE WORLD, (Ger. *Kinder der Welt*), a novel by Paul Heyse, q.v. (later Paul von Heyse), published in Germany in 1873. The work is the literary echo of the discontent and rebellion against the existing order—political, religious, social, and economic—which, beginning in the universities, spread through Germany in the period between the revolution of 1848 and the Franco-Prussian War. It is a perfect example of the *Tendensroman* (novel of purpose), which such times of unsettled thought and altered values engender. Except in its treatment of women, which is extremely romantic, *Children of the World* is the philosophy of Arthur Schopenhauer and David Friedrich Strauss (qq.v.) reduced to novel form.

CHILDREN'S AID SOCIETY, The, a nonsectarian organization founded in 1853 "to improve the conditions of poor and destitute children in the City of New York and the State of New York." Charles Loring Brace, the founder and first secretary of the society, was particularly fitted for the task. After training for the ministry, he had traveled and studied living conditions in the large cities of Germany, Hungary, England, and Ireland. Returning to New York he worked among the wretched and outcast. After a year's experience among adults in the Five Points, he became convinced that "an effort to reform those old in sin was hopeless." Out of this grew his determination to devote himself to the cause of children.

Mr. Brace's unique contribution to social work was his belief that the best place for a homeless child was in a private family home where he could grow up loved and protected like other children. Looked upon as somewhat revolutionary in their day, his ideas have long since become practice in social work, and out of this philosophy has grown The Children's Aid Society's present foster home work and that of other organizations which stress foster home rather than institutional care.

In 1951 the society was providing 12 essential services for more than 45,000 children of all races and creeds from infancy to 21. These services include foster home care, homemaker service, boys' and girls' clubs on a neighborhood basis, with health examinations and medical supervision, nourishing lunches, dental clinics, individual attention to problems of children, counseling and employment service, psychiatric service, convalescent care, and summer camps.

CHILDREN'S BUREAU, of the Social Security Administration, United States Department of Health, Education, and Welfare, was established by Congress April 9, 1912, to investigate and report "upon all matters pertaining to the welfare of children and child life among all classes of our people." In 1935, under the Social Security Act, the bureau was made responsible for the administration of grants to the states to enable them to extend and improve their services.

After 33 years in the Department of Labor, in 1946 the bureau was transferred to the Federal Security Agency which, in 1953, became the Department of Health, Education, and Welfare.

Under its basic act, the bureau makes studies of conditions that are a hazard to the well-being of children, and of the effectiveness of measures designed to prevent and alleviate such conditions. On request, it gives advisory service to state and local agencies regarding methods of conducting programs aimed at promoting the health and welfare of children. It issues publications for professional and lay use. Four of the bureau's most widely used publications for parents are: *Prenatal Care*; *Infant Care*; *Your Child from One to Six*; *Your Child from Six to Twelve*. In 1954, it released a fifth in this series: *The Adolescent in Your Family*.

Congress has authorized a total of \$41,500,000 in annual grants to be given to the states. Actual appropriations, which are administered by the bureau, totaled \$30,000,000 (fiscal year 1955).

The bureau carries responsibility for recruiting and providing technical help to specialists in children's services sent to other countries by the Foreign Operations Administration, and for de-

veloping programs of study and observation for specialists from other countries coming to the United States. The chief of the Children's Bureau is the United States representative on the executive board of the United Nations Children's Fund.

CHILDREN'S COURTS. See **CHILD WELFARE.**

CHILDREN'S CRUSADE, The, a singular movement in 1212, preached in France by Stephen, a peasant boy, and in Germany the same year by Nicholas, also a peasant boy. Some 90,000 children left their mothers and schoolmasters in the spring "to rescue the Holy Land from the infidels," and ships were placed at their disposal. The French contingent embarked at Marseilles in August; part perished the same month by shipwreck on the island of San Pietro, and the rest were sold into slavery to Mohammedans. The German contingent reached Genoa in August, and was utterly dispersed by various disasters before the next spring. See also **CRUSADES.**

CHILDREN'S LITERATURE. In its usually accepted sense, children's literature includes only that literature intended for the entertainment or instruction of children. In its wider and truer sense, it embraces all literature marked by simplicity and vividness of expression and that piquantly imaginative quality demanded by young minds. That portion of the world's great literature having these characteristics has been taken over bodily by the children. Folklore and fables, such as Aesop's *Fables*, romantic adventure, as in *Arabian Nights*, and the whimsical creations of great writers, such as Jonathan Swift's *Gulliver's Travels*, Daniel Defoe's *Robinson Crusoe*, and Washington Irving's *Rip Van Winkle*, possess these qualities and have been accepted by the children.

Notwithstanding the fact that children's literature is not separated from adult literature by any clearly defined partition, it is possible to trace its origin and growth backward from the present products to their sources, and thereby show a continuity of characteristics which mark children's literature as such.

Through all recorded history children have taken to themselves the folk tales, many of the ballads, the legends and myths, the tales of magic and knighthood, the adventure and exploration, the jingles, part of the lyrical poetry, and the epics.

History reveals four—fairly distinct periods that have contributed to the present diversified field of children's books, although, as periods, they have no exact beginning or ending, but, rather overlap and merge imperceptibly. First came the ancient precepts, tales, and poems chiseled on stone, clay or brick tablets, followed by, or used concurrently with, papyrus rolls (strips made from tough water plants). Next came the age of compilation in medieval times, when monks collected the ancient works and recopied them upon parchment or vellum, adding current tales and poems. The third period was inaugurated with the discovery of the printing press and its spread to all countries, widely disseminating the literature of all lands and revealing, incidentally, that the folklore that had entertained children in separate countries was essen-

tially the same material, differing in versions only. The fourth period is the modern age, which may be called the consciously experimental period, when, for the first time, children's own interests are studied to determine what forms of literature give them most pleasure and instruction, and to devise new forms suited to individual interests.

ANCIENT PERIOD

Egypt.—The oldest manuscript yet discovered that addresses words directly to children comes from the banks of the Nile, and was a production of Ancient Egypt. It is *The Precepts of Ptah-hetep*, contained in a papyrus roll now preserved in the Bibliothèque Nationale at Paris. Although this papyrus was written around 2600 B.C., it is a compendium of much older precepts dating back to, or even beyond, 3850 B.C. This book, lofty in tone and style, with a viewpoint toward life that is highly civilized even according to modern standards, contains advice for the young: "Be not puffed up with your own knowledge, but honor the truly wise. Nor shall you fail to honor even the simple . . . A good son is a gift of the gods. Such a son does more than is demanded of him and seeks to please the soul of his father, and strives to increase his strength through righteousness . . ."

The earliest manuscripts, so far exhumed, contained mostly precepts and advice, but it was not long before the current folk tales were likewise recorded. The earliest known manuscript of fictional stories is contained in what is known as the Westcar Papyrus, written about 2800 B.C., and preserved for modern scholars in the Berlin Museum. It, too, is from early Egyptian literature, and consists of narratives supposedly told to his sons by King Khufu, or Cheops, builder of the Great Pyramids. Like the majority of Egyptian literature, it deals with magic and the dramatic acts of gods and magicians. The Egyptians were lovers of these tales of magicians, filled with stories of animals that talk and who, in their human personifications, reveal the whimsies of human nature.

Typical of early Egyptian tales is a story called *The Shipwrecked Sailor*, dated about 2500 B.C. and now preserved in Russia. A forerunner of *Robinson Crusoe* and *Swiss Family Robinson* (q.v.) it tells of a shipwrecked vessel from which one lone survivor reaches the Isle of Plenty, where, with a talking serpent as his companion, he lives by his own resources on the abundance of nature.

Babylonia and Assyria.—Babylonia, both before and after it was conquered by the Assyrians, was rich in stories and poems that form a source for later children's writers. Accounts found on burnt brick and baked clay tablets have been uncovered dating back to 2000 B.C., although the golden age of Babylonian literature was from about 668 to 608, when the ruler, Sardanapalus (q.v.) gathered a remarkable library at Nineveh, collecting the ancient papyrus and tablets and having them translated. Typical of early Babylonian tales was one of a serpent who complained to the sun that the eagle had devoured all her young. The sun advised the serpent to ensnare the eagle by means of a dead ox as bait, but the wise eagle escaped the snare.

Greece.—*Homer.*—On library shelves for modern children are many titles such as *The Children's Homer*, *The Iliad for Boys and Girls*, *The Odyssey for Boys and Girls*, and various

adaptations of the Homeric legends. All of these spring from the same source, the two great epic poems of ancient Greece, the work of the master storyteller, Homer.

Tradition pictures Homer as a blind poet wandering from town to town reciting his narrative of gods and men, but history has not yet authenticated either the time nor the personality of the man. His great books come from an age before literary history, put by some as early as 1159 B.C., by others as late as 685 B.C. The legend of his blindness may have arisen from the known fact that certain rulers in ancient days blinded their favorite bards so that they might not wander away to other places. Seven different cities have claimed Homer as native son; however, by the time the Greek historians of the 5th and 4th centuries B.C. began to investigate origins and study documents on the Homeric epics, the man himself was already a legend.

No matter what or who the great author known as Homer truly was, the characters he created and the scenes he depicted form a basic part of children's literature. The theme of the *Iliad* (q.v.) is the final incident in the siege of Troy by the Greeks, and a large part of Greek mythology is revealed in the poem. The *Odyssey* (q.v.) concludes the story of the siege of Troy, with the dramatic trick of the wooden horse, and recounts the adventures of Ulysses (called Odysseus in Greek) on his way home, together with the experiences of his wife, Penelope, while awaiting him.

Aesop.—The second Greek of primary importance in children's literature is the slave, Aesop (c.620-560 B.C.). Aesop's name has been given to a whole class of animal tales told to point up a moral. He did not originate all the fables attributed to him, nor did he originate the form, since fables are found in early Egyptian literature, but he brought to the fable a dramatic liveliness that children enjoy. He may not even have committed his fables to writing; the earliest record is of a collection of ten books of Aesop's *Fables* made by Demetrius of Phalerum (345?-283 B.C.), but this collection was not preserved. The Latin translations are the ones familiar today, the best known of which is the collection of Maximus Planudes, a monk of the 14th century, in whose edition are added many tales from Oriental sources. Aesop, although once a slave of Iadmon of Samos, must have been freed, since he once conducted a public defense of a citizen. He used fables to persuade and instruct as well as to entertain; he created laughter in order to reprove and admonish. (See also **FABLES OF AESOP.**)

Greek Historians.—Not only did Greece give to children's literature the first great epics and fables, but it also gave the first great history. History—one of the primary fields of children's reading interests—may only develop late in a nation's life, after centuries of recorded national experience have built a unified flow of personalities and activities. The higher a nation's civilization, the greater its recorded history. Ancient Greece achieved an unprecedented height, and of its men and women of genius in the 5th century B.C., Herodotus and Thucydides were the greatest historians, not only of their time but of all time.

Herodotus.—Herodotus (c.484-424 B.C.) wrote one great work upon which much children's literature has been based, both in exact translations and adapted forms. This was his *Histories*, a

narrative account of the wars waged by the Persians against the Greeks.

Thucydides.—Thucydides (c.454–399 B.C.), the first wandering war correspondent, wrote a *History of the Peloponnesian War*, a work remarkable for the fidelity and exactness of its details. He began the personal observation, factual narrative that flowered in the 20th century.

Xenophon.—Xenophon (c.434–355 B.C.) followed Thucydides, continuing, with his *Hellenica*, a history of the Greeks, from the point where Thucydides left off, and adding the *Anabasis* (q.v.), an account of the expedition of Cyrus, which has become the first text in Greek given to modern students.

Plutarch.—Plutarch (c.46–c.125 A.D.) was a biographer, the first to write biography in a narrative form that children could appreciate. He accumulated, from travels in Egypt, vast stores of historical and mythological lore, and examined public and private documents in Greece and Rome. From this material he wrote his *Parallel Lives*, character studies of illustrious Greeks and Romans in pairs: Demosthenes and Cicero, Alcibiades, and Coriolanus. There were in all fifty lives of which 14 have been lost; from those remaining, dramatists and writers, including Shakespeare, have drawn copiously for material.

India.—*Sutta-Pitaka*.—India possessed a written literature before 2000 B.C., but much of it was written on palm leaves and could not be preserved. Copies were made of some small part of it, however, before it crumbled to dust. The first work that forms a readily observable source of children's literature is the *Sutta-Pitaka*. The *Sutta-Pitaka* tales are embodied in one of the *Three Pitakas* or *Baskets*. (See also *PITAKA*.) They are stories accumulated around the few known utterances of Gautama Buddha (563?–483 B.C.).

Written between 300 and 500 B.C., the *Sutta-Pitaka* contains the Buddhist birth stories (Buddha was supposedly reborn many times) called the *Jatakas* (q.v.). A *Jataka* is a Buddhist birth story, or a legend or fable supposedly told by Buddha to illustrate an ethical lesson. In reality, the *Jatakas* are the accumulated folklore of unknown generations of Indian storytellers, happily gathered together in one volume of legends, jungle lore, and fables. It was to be known under many names in the centuries that followed: *The Book of Five Hundred and Fifty Jatakas*, and in an even more popular version, *The Panchatantra* (q.v.) or *Five Books*. The latter book spread through the East, accumulating new tales from local folklore as it moved, and was called the *Hitopadesa*, or Book of Good Counsels. As it moved on into still other countries, references to Buddha were eliminated and the tales, when told in a Sanskrit version, introduced a wise old sage who supposedly told the stories to instruct the sons of a king. By the 6th century A.D. it had reached Persia, where it was first called *The Lights of Canopus*, referring to the star of wisdom, Canopus, and later by the title widely known today: *The Tales of Bidpai*. In this latter edition, the old *Jatakas* were told to an Indian king by a philosopher named Bidpai (q.v.). The Persians added to the original and accumulated tales new romances of magic, human shrewdness, and adventure, for the Persians were master storytellers and excelled in imaginative romances.

The Arabs got the collection from the Persians, calling it *Kalilah and Dimnah*, after the two jackals of the original *Jatakas*. The Jews got the stories from the Arabs and, after translating them into Hebrew and adding new inventions, carried them into western Europe. By the 13th century, the monks were copying them in a hundred monasteries, putting them first into Greek and Latin, and later into the vernacular.

In the 20th century, they are found in school readers, often headed erroneously *Aesop's Fables* or *LaFontaine's Fables*; in abridged translations such as Ellen Babbitt's *Jataka Tales* and *More Jataka Tales*; in adaptations, perhaps unwitting, of writers like Rudyard Kipling and Joel Chandler Harris, and in the stories that form the basis for *The Arabian Nights*.

Another Hindu collection important to the stream of children's literature is *The Seventy Tales of a Parrot* (SUKA SAPTATI, q.v.), later called *The Seven Wise Masters*. In this book each day, for seven days, romances and legends were told to a king. It is not in itself a children's book, but, together with the Arab version of the *Jataka* tales, *Kalilah and Dimnah*, it formed the basis for that great landmark in children's literature, *The Arabian Nights*. It has been because of this similar source of *The Arabian Nights* and the *Jatakas* that historians have sometimes given two separate tracings to these collections.

The Arabian Nights.—This collection, but its own contents, is recognizable as not all Arabian. It is obviously of Indian origin through the Persian, with a flavor of Chinese. Each land contributed something of its own nature until, when the medieval monks began its copying, it breathed the mystery of India, the magic of Egypt, the perfume of Persia's rose gardens and incense, and the romance of Arabia, to which were added the philosophy of China and the Hebrews. Also called *The Thousand and One Nights* because it contained, in its final accumulation, 1,001 stories hung on a single thread of narrative, it is one of the great books of all time. The titles of its stories call back the world of childhood: *Ali Baba and the Forty Thieves*, *Sindbad the Sailor*, *Aladdin or The Wonderful Lamp*, *The Merchant and the Genie*, *The Merchant of Bagdad*.

Ramayana and Mahabharata.—Besides the *Jatakas*, which grew and branched into an unparalleled literature, the Hindus also contributed two great epic poems dealing with the history and mythology of the Aryan or Hindu conquerors of India. These are the *Ramayana* and *Mahabharata* (qq.v.), both accumulations of legends and traditions in poetic form that later appeared in medieval translations and were incorporated, after the discovery of printing, into chapbook form for children.

Persia.—There is no one date which may be set as the end of the ancient period of composition and the beginning of the medieval period of compilation. But if there was any one nation that formed a link between the ancient composers and the medieval compilers, it was Persia. Early Persians and Hindus intermingled and their written literature was the same. But about the 4th century B.C. they separated and the Persians went westward to the highlands of what is now called Iran. The jungles of India inspired an animal-fable type of literature with the Hindus, but the highlands inspired tales of mysticism, magic, and romance with the Persians. Eventu-

ally a book evolved called the *Shah Nameh* (q.v.) or *Book of Kings*.

The Shah Nameh.—This was an incredibly lengthy compilation of an unknown scribe or scribes, containing 60,000 couplets in crude verse of folktales, legends, romance. From this book came such tales as *Sohrab and Rustum* (q.v.), made famous by Matthew Arnold.

Omar Khayyam.—From the Persians, too, comes such delicate poetry as that of Omar Khayyam. His *Rubáiyát*, written in the 11th century, is still singing in the pages of beloved little volumes. Persian literature, both prose and poetry, had a beauty and fragrance all its own, compounded of roses, spices, moonlight, enchantment, and the song of nightingales; it was truly "youth's sweet-scented manuscript." When the glory that was Persia's was over, it was the 14th century, and the medieval world had brought newer, but not better, songs and tales.

MEDIEVAL PERIOD

Monastic Compilers.—In conventional history, the Middle Ages are the thousand years from the middle of the 5th century A.D. to the middle of the 15th. But in literary history there is no such sharp division. Long after the genius of Greece and Egypt had died away, Persia was still composing new tales and embroidering the old ones, but Persia was an isolated oasis of literary creation. In Europe, the early centuries of the Christian era saw little new in literature, and wars and conquests temporarily effaced much of the old. Daily life in Europe, during the 5th, 6th, and 7th centuries was at a low level, intellectually. What little literature there was, both for children and adults, may be divided into the German (including Scandinavian and English), Celtic, French, Spanish, Italian. They were interdependent, borrowing from each other, with no one country producing much of merit that was new, except for the five flashes of literary brilliance that are discussed in the paragraphs immediately following.

The influence that may have kept all literature from being blotted out during the ten centuries of the Middle Ages, a period of incessant warfare, hard physical conditions and consequent ignorance, was the work of the scribes in monasteries of the Benedictine type. Benedict (St. Benedict of Nursia), born in Nursia (now Norcia), Italy, around 480 A.D., was profoundly impressed by the universal decay of education and the possible loss of the ancient learning and literature. He founded monasteries as a refuge for scholars and, before his death, around 544 A.D., he had set up schools in the monasteries for the education of young boys.

The rapidly spreading monastic organization, as started by Benedict, was a significant factor in the preservation and augmentation of children's literature, for the monks were set to the task of collecting and transcribing upon parchment and vellum the ancient manuscripts, and of writing texts for the pupils.

Closely associated with Benedict and with one of his prominent followers, Pope Gregory the Great, was Cassiodorus (490-585). An Italian, like Benedict, and a man of wealth, Cassiodorus founded a monastery upon his private estates, and traveled far to find literature for translating and transcribing. He was one of the profound scholars of his day as is shown in the extant fragments of his *History of the Goths* and his

Letters, both of which works contributed to the learning of the young.

The spread of monasteries of the Benedictine type in the 7th and 8th centuries made possible the restoring of much of the ancient works to readable form, the preserving of some sort of education with both elementary and advanced texts, and the beginnings of a new cycle of folk tale collecting. As a result of their missionary activities, the Benedictines penetrated England, Holland, Germany, Scandinavia, and Poland, until, by the end of the 11th century, Benedictine houses existed by the hundreds, giving seclusion and security to scholars who sometimes spent their entire lives in their austere, quiet cells, laboriously, often artistically, producing a written literature.

The majority of the manuscripts produced in the monasteries was strongly tinged with theology, but the copying was not entirely confined to saintly precepts and instructional texts. Tales from Egypt, fables from India, romances from Persia, and current folk tales and heroic cycles were also transcribed. A form of writing called dialogues, based on an ancient Greek innovation, was worked out for the instruction of the young, and riddles came into vogue. The use of the riddle and puzzle in teaching children is exemplified in a book by Aldhelm (c. 640-709) called: *The Number Seven, Meters, Enigmas, and Rules of Feet*, the enigmas referring to puzzles and riddles designed to teach metric problems.

Outstanding among the monastic scholars of the day were Bede, Alcuin, and Aelfric.

Bede (*Beda* or *Baeda*).—Bede, sometimes called the Venerable Bede, (c. 673-735), was important as an historian. He composed, among other works, a grammar, a book on natural phenomena, and an *Ecclesiastical History of England*, which, translated later from Latin into Anglo-Saxon by King Alfred, was long a required text for scholars.

Alcuin.—He was born in York (c. 735-804) and had perhaps the widest influence of his time, because he was the first to carry the growing learning of the British Isles to western Europe. He traveled to the court of Charlemagne, and there his influence displaced that of the Italians, who had occupied chief place in the new renaissance of letters. He wrote poems, histories, and elementary texts: grammar, rhetoric, mathematics. In his *Dialogue of Pepin* we see the intellectual exercises by which he taught the young.

Aelfric (955-1020).—Called the Grammarian, he was an English abbot and author educated at the Benedictine monastery at Winchester. He wrote 40 ecclesiastical homilies, a Latin grammar, and a glossary; more important were his *Lives of the Saints*, some of which were sufficiently lively to entertain as well as instruct the young. His *Colloquium*, a Latin dialogue designed to aid his pupils in Latin conversation, became widely used. Latin, at this date, was still regarded as the appropriate vehicle for works of any literary pretensions.

The Benedictines, although themselves producing no brilliant and lasting pieces of children's literature, recognized the need of books written especially for children. They were not world-minded with regard to history, as Herodotus had been, but they wrote histories that perpetuated the story of their times and, in addition, they gave to children encyclopedias of

what science they knew, chronology, astronomy, mathematics, and homilies on ethics. Some of the manuscripts copied by medieval monks had extraordinary beauty, the calligraphy lovely as a painting, the parchment or vellum decorated with scrolls, flowers, and human figures.

It was however, not out of the monasteries, but growing from the folk lore and romance cycles of the unlearned populace that the five great pieces of medieval literature came into existence which were to become a basic part of children's literature.

Song of Roland.—In France, the enduring masterpiece was *The Song of Roland*. This was one of hundreds of *chansons de geste* (q.v.) (songs of heroic deed), a type of epic in which the poetical and romantic French excelled. The material of the popular *chanson* dealt with the exploits of some national hero, mythical personage, or historical ruler. Roland was a knight who accompanied Charlemagne's army to Spain, and whose refusal to sound the horn which would summon the emperor to the rescue, during the army's retreat, forms the most dramatic episode of the narrative.

Beowulf.—An original piece of early Anglo-Saxon literature was *Beowulf* (q.v.), composed after the German invasion of Britain in the 5th century. The British Museum has a manuscript of *Beowulf* dated the year 1000, but it is considered much older than that. It must have been a recited tale of great age before it was committed to writing, for although the language is Anglo-Saxon, the hero and scenes are Scandinavian and German. The story tells of a young hero, Beowulf, brave and strong, who battles a monster (Grendel) in the hall of a king and slays him, but is later killed by a dragon. This old tale, clearly of the *Jack the Giant Killer* variety, is still being published for children in modern variants. It has many dramatic and colorful parts.

The Eddas.—The third work originated in the Scandinavian countries where there had been developing a cycle of heroic legends comparable to the Homeric tales. First collected in Iceland in the 13th century by a poet, Snorri Sturluson, they were called *Edda*. This first collection is now called the *Younger Edda*. A second book of Scandinavian hero tales, collected much later, in the 17th century, was called the *Elder Edda*. The honor of having been the homeland of the *Edda* has been claimed by Norway, Iceland, the British Isles, and Denmark, but Iceland points out with pardonable pride that it was the first to collect them. The *Edda* contained *The Story of Grettir the Strong*, and *The Story of the Volsungs and the Nibelungs*. These sagas (stories), passing over to Germany, became the basis of the Wagnerian tales of Siegfried and Brunhilde. See also EDDAS, THE.

King Arthur.—Growing in the Celtic and French lands all during this medieval period was a cycle of romance, epics, legends, and ballads clustered around a central figure: King Arthur. There are few children in Europe or America today who have not heard some wisps of the tales about King Arthur and his Knights of the Round Table, yet the origins of these engrossing and deathless narratives are lost. They were probably the joint product of France and England, or rather, of those peoples who occupied the opposite coastlines of the channel, during the early medieval times. It is not even

revealed historically whether there was a real Arthur whose heroic exploits started the cycle. It is only certain that after generations of verbal embellishments, and after many written versions had been circulated on both sides of the channel, there came the happy day in English literature when Sir Thomas Malory, in the second half of the 15th century, gave to the world *Morte d'Arthur* (q.v.). This great work brought to the world's children the adventures of the peerless King Arthur and his Knights of the Round Table: Launcelot, bravest of the 150 knights, Galahad, purest of them all, Launfal, Galahad's father who was King Arthur's steward, Queen Guinevere (Guanhumara)—unfaithful to Arthur, alas—and all the heroic men and lovely women whom poets and authors and dramatists have pictured ever since. The most popular later interpretation was in Tennyson's *Idylls of the King* (q.v.).

There are three separate narrative cycles associated with the Arthurian legends. First there is the story of Arthur's marriage to Guinevere, her love of Launcelot (Lancelot), and Arthur's death. The second is the quest of the Holy Grail, that sacred chalice in which the blood of Christ was preserved, and its finding by the one pure knight, Galahad. The third story is that of Tristan and Iseult, a completely separate tale, which was later set by Wagner into some of the world's most exalted music. See also ARTHURIAN ROMANCES; GRAIL, THE HOLY; TRISTAN UND ISOLDE.

Gesta Romanorum.—The fifth great work of medieval times was the *Gesta Romanorum* (DEEDS OF THE ROMANS). This collection, probably compiled about the end of the 13th century, was one of the most popular books of the time. Almost every monastery had its copy from which the monks transcribed new and more beautifully designed copies; storytellers and ballad singers built new romances upon its contents. It was a collection of anecdotes and tales, of fables and romances, that bear the ancient imprint of the Hindu Jatakas and the later *Panchatantra*. The *Gesta Romanorum* was a source book for Chaucer and Shakespeare, as well as for later authors. Because the book was written in the conventional Latin, it was given a Latin name, but the name was inappropriate, since the book comprises fragments of various origin, Oriental and European. The germ of the tale *Guy of Warwick* (q.v.) was contained here, and *Darius and His Three Sons*, stories that, in chapbook form, English children would learn by heart. Chaucer borrowed freely from it; Spenser used it for the basis of his *Faerie Queene* (q.v.); Shakespeare took over plots for *King Lear* and *The Merchant of Venice* (qq.v.). When printing was introduced, the stories from the *Gesta Romanorum* were among the first published.

Canterbury Tales.—Although Chaucer (1340-1400) is not in a direct line of children's literature, his *Canterbury Tales* (q.v.) had an influence which cannot be ignored. Chaucer's close observation of mankind, his interpretation of emotional reactions, his fidelity in recording speech and action, were forerunners of the 19th century realism in children's stories; from the *Canterbury Tales* have come some familiar themes in children's literature. See also CHAUCER, GEOFFREY; MILLER'S TALE OF THE CARPENTER, THE; NUN'S PRIEST'S TALE, THE.

CHILDREN'S LITERATURE

"The King and Queen of Hearts were seated on their throne . . . the Knave was standing before them, in chains near the King was the White Rabbit, with a trumpet in one hand, and a scroll of parchment in the other. In the very middle of the court was a table, with a large dish of tarts upon it. . . ."

These words of Lewis Carroll were illustrated by Sir John Tenniel's famous drawing of the court scene for the chapter, "Who Stole the Tarts?", in *Alice in Wonderland and Through the Looking Glass*.

INFLUENCE OF THE PRINTING PRESS

It is natural that few books, except texts, were written in ancient and medieval days solely for children, for the production of a book was a laborious task. Moreover, paper was not plentiful, even by the 14th century; scribes still copied on parchment, or the precious and beautiful vellum (a leather especially processed).

The Chinese were the first to invent letterpress printing: the art of producing impressions by means of pressing an inked relief surface onto paper or other material. But China did not build a children's literature with their art. There is no certainty as to the date of the first European use of printing from movable type, nor which country used it first. It is only authenticated that by 1464 it had been introduced into Germany, and shortly thereafter into Switzerland, France, Holland, Belgium, and Spain. In all these countries, folk tales, because they were short, entertaining, and easy to print, were put into circulation, but one cannot picture children as reading them avidly, because few children could read.

Caxton.—William Caxton (c.1422–1491) was the first English printer. His name has outstanding significance in the history of children's literature, for he not only printed the old folk tales, many of which were crudely translated from the French or adapted from Italian translations of Greek and Latin classics, but, because England as an island had to build an early trade by sea in order to exist, he was able to send his little books abroad as soon as they were printed. Thus the English versions of old tales and poems became widely dispersed before the year 1500. Even well into the 20th century there were countries which had not dispersed their native writings, particularly writings for children.

In 14 to 15 years, Caxton produced around 100 known publications, and probably others which did not outlast his time. For children's reading, his most memorable books were *Reynard the Fox*, *Troilus and Cressida* (*Troilus and Cresida*), Malory's *King Arthur* (*Morte d'Arthur*), *The Golden Legend*, *Fables of Aesop*, *The History of Troy*, and *The Story of Jason*.

When Caxton died, his press passed to his assistant, Wynken de Worde (q.v.), who refined the art of printing, and whose publication of the *Gesta Romanorum* perpetuated these old tales for children. Wynken de Worde's edition, now kept at St. John's College, Cambridge, is the earliest one extant of this famous collection.

Hornbooks.—Paper was still not too plentiful, and children were, and are, destructive; therefore, around the year 1550 a new "book" was invented for their use: thin printed sheets pasted upon wooden paddles, covered by transparent horn and bound with brass. Known as hornbooks (q.v.), these gave elementary instruction only: the alphabet, syllables useful for the beginning reader, and the Lord's Prayer. Arithmetical exercises and religious instruction also appeared on some of the hornbooks.

Battledores.—Chiefly because it was durable, the hornbook lasted for 200 years in some form, yielding finally, around 1769, to the battledore, which consisted of sheets of cardboard folded over in book form. The battledore, too, was designed for elementary instruction only; it contained reading lessons for the beginner as well

as the alphabet, syllables, and numerals. In the New World, it was superseded by the *New England Primer* (q.v.), but in England, following the usefulness of the hornbook, it spread the knowledge of reading so that children of all classes were able to enjoy England's next publishing venture, the chapbook.

Chapbooks.—During the 17th and 18th centuries, England's presses, rapidly increasing in number, turned to an original type of mass literary production. Because more people, including children, were reading for entertainment, cheap books were devised, called chapbooks (q.v.) (from the early Anglo-Saxon word *ceap*, later pronounced *chap*, meaning cheap or common). The little books were peddled by chapmen (ceapmen). Merely pamphlets in their earlier forms, they consisted of a minimum of 4 and a maximum of 70 pages, folded but unstitched. They sold at from a penny to sixpence apiece, and commonly sold in lots, tied together. They were peddled over England and Scotland, carried by the same chapmen who peddled trinkets and articles of houseware and clothing to the farms, hamlets, and towns. For the first time in any country the populace had "books" in their homes—if these badly printed sheets may be termed books. Chapbooks contained the ancient tales of India, Greece, Rome, and Persia, the medieval romance cycles and narratives authored by Chaucer, little jingles and rhymes for the nursery age, fairy tales pirated from France and Italy. Later, chapbooks were exported to America, leavening the gloomy Puritan literature of the day. *Jack the Giant Killer* (q.v.) was a prime chapbook favorite with children, as was the perennial *Sir Bevis of Hampton*¹ (q.v.), the story of the doughty lad, sold to the heathens, who slew 60 for deriding Christianity, was given a wonderful horse, a mighty sword, captured a giant, and married a princess. Sir Bevis was the prototype of a hundred English literary heroes.

Robinson Crusoe.—During the 18th century, while chapbook popularity was at its height, England produced one immortal book of a different nature and length which was to be unique in the joy it would give to childhood. This was *Robinson Crusoe* (q.v.), published in 1719 by Daniel Defoe (c.1659–1731). Its theme of the solitary individual shipwrecked and surviving by his own resourcefulness was reminiscent of *The Shipwrecked Sailor*, written over 4,000 years previously in ancient Egypt, but its treatment was a new and fascinating realism. Defoe is justly called the first great realistic novelist; his imagination, which pictured the self-reliance and heroism of the human being cut off from human aid, invented such details that every adventure of Robinson Crusoe is still believable.

16TH, 17TH, AND 18TH CENTURIES

France.—*Fairy Tales.*—Always a poetical, artistic, and romantic country, France was the first to put traditional fairy tales in such charming and dramatic style that they became great literature as well as folklore. Like all new literary developments up to this time, the French fairy tale was first created to entertain adults. The courtiers of Louis XIV are credited with the innovation of this new art: the telling and writing of alluring tales of fantasy, designed to

¹ Also known as Sir Bevis of Southampton or sometimes Hamtown.

amuse the noble ladies and gentlemen of a court which demanded constant amusement. In 1697, Charles Perrault (1628-1703), already an elderly man, published a collection of eight stories which have remained a landmark in children's literature: *Contes de ma Mère l'Oye* (*Tales of Mother Goose*). These included *The Sleeping Beauty*, *Bluebeard*, *Little Red Riding Hood*, *Puss in Boots* (qq.v.), *Cinderella*, and *Tom Thumb*. Perrault, an architect, who published first in the name of his son, fearing ridicule, said that he had heard the stories from his son's nurse. They were not new tales; the origin of *Cinderella* alone goes back before historic records; Perrault's genius gave them universal appeal. Today, a monument to Perrault stands in the gardens of the Louvre in Paris—a life-size bust surrounded by a ring of dancing children, *Puss in Boots* in their midst.

Among the writers of original and adapted fairy tales who followed Perrault in France, three aristocratic ladies excelled: Marie Catherine Jumel, Countess D'Aulnoy; Madame Henriette Julie Murat; and Mademoiselle de la Force. The Countess D'Aulnoy is best remembered by *The White Cat*, *The Yellow Dwarf*, and *The Blue Bird*; Madame Murat's stories were sophisticated; Mlle. de la Force is remembered for *The Enchanter* and *Green and Blue*, tales of exaggerated marvels. See also FAIRY TALES.

Italy.—The rapid spread of printing as an art tangled the thread of children's literature as it passed from one country to another. Throughout all civilized lands, compilation and original productions appeared simultaneously and interwove because of growing trade and communications. Thus the contributions of 17th century France are listed before those of Italy in an historical tracing because the work of France was dispersed earlier, yet the stories of France may acknowledge to be based upon earlier Italian work. There were linguistic difficulties in Italian writings which confined them to small areas long after the work of French writers was given to the world.

The earliest known Italian collector of tales that would appeal to children was Giovanni Francesco Straparola, whose book, now known as *Straparola's Nights*, was published in 1550, and in complete form in 1554. Of his 74 stories, *Puss in Boots* and *Beauty and the Beast* were the immediate forerunners of the French variants.

Of equal importance in Italian letters was Giovanni Battista Basile (1575-1632), whose *Pentamerone* (*Five Books*) was written in about 1620, but in so archaic and difficult a Neapolitan dialect that the book was understandable to few. For over half a century it remained unknown not only to the world but to Italy itself. Basile, a gentle, imaginative poet, was born in Naples; he collected his stories as he traveled about the country as a soldier—a profession he detested and from which he took refuge in a mental world of charming fantasy. He divided the *Pentamerone* into five days, each containing ten stories, among which were *Cinderella*, *Rapunzel*, *Snow White*, *The Sleeping Beauty*, and *Hansel and Gretel*. Thus, Basile predated by many years the variants of these stories written by Perrault and the brothers Grimm.

Spain.—The Spanish, even more than the French, are a romantic people, fond of extra-

gant tales of adventure. Of their romantic novelists of this period Miguel de Cervantes (1547-1616) is acknowledged the master. His most celebrated work, *Don Quixote* (q.v.), gave to Spanish children and later to the children of the world a whole series of little tales all woven around the adventures of the absurd hero, Don Quixote, who, having read too many accounts of chivalry, goes forth into the world to right all wrongs. *Don Quixote* was translated into every language in Europe, and excerpts from it appear in innumerable children's anthologies. For some reason, it was never as popular with children of the United States as of other countries, which is unfortunate, for the book reveals the Spanish pride in manners and chivalry, as well as the inimitable Spanish humor.

Religious Writers.—No other period in children's literature is as clear-cut and definitive as the one now known as the Religious Period. Starting with the work of the monastic scribes who, naturally, injected theological doctrine into their own writings, religion as the basic theme of children's books reached its flowering in England around the year 1649. For perhaps a generation before this time church leaders had been alarmed at the rapid spread of chapbooks among the populace, and at the consequent freedom of thought and dissemination of knowledge which the art of printing was creating. Other social forces, besides the increasing literacy, were at work, too, and the result was that measures of repression were inaugurated by both church and state officials. A tremendous religious revival was started in England; the Bible replaced the chapbooks in the presses of the country, and *Guy of Warwick* yielded to the Old Testament Bible reading was carried on in churches and homes. Then a group of people, called the Puritans, a sect of English Protestants that arose in Elizabeth's reign, became a dominant force. I was from this group that the Pilgrim founder of New England came. Although the Puritans were strong upholders of freedom of conscience and simplicity of worship, they were scrupulously and narrowly strict in their religious life. Speedily they censored the reading of children. Their literature took on a rigid morality and a morbid concern with death. Chapbooks were still printed, to fill popular demand, but even the ungodly were filled with fear to give them to the children.

Typical of the English writers for children at this time, was the Reverend James Janeway. The book for which he is best known in the annals of children's literature was titled: *A Token for Children: being an Exact Account of the Conversion, Holy and Exemplary Lives, and Joyful Deaths of Several Young Children. To which is now added Prayers and Graces Fitted for the Use of Children*. This melancholy treatise told of good children who lead exemplary lives, to wit: brooded on eternal damnation and preached salvation to their elders, happily departing early to a better land.

The difference between these religious writers and the early monastic scribes, in the writing of children's books, was that the scribes interspersed doctrine with elementary educational material, whereas the later religious writer turned the doctrine into narrative channels and omitted the education. This does not mean that the Puritans ignored the education of the young; on the contrary, they fostered it in the form of

texts with a strong religious undertone but added to texts their innovation—the doctrinal narrative.

Pilgrim's Progress.—The theme of salvation and damnation expressed itself in only one great book: *Pilgrim's Progress* (q.v.) by John Bunyan (1628–1688). Bunyan was a man of the people, a tinker, and as such was not subjected to that influence which raised Elizabethan prose to the heights. He could only express the popular religion, because it affected his life deeply. His book became a second Bible, and children, permitted to hear it—indeed, forced to hear it—enjoyed the mystery and allegory without having to understand the theology. The theme of *Pilgrim's Progress* is a dream-allegory that represents the struggles and triumph of the Christian life. Its success with children was purely accidental, never dreamed of by its author, who, influenced by John Foxe's *Book of Martyrs*, had sought only to picture religious truths as he believed them.

The Puritans, arriving in New England, brought with them their rigid concepts of what children's literature should consist.

New England Primer.—The first important textbook published in the New World, possessing leaves and binding, thus differentiating it from the hornbook (which was almost immediately imported for children's use), was the *New England Primer*, first printed around 1649. This book was a combination of alphabet, spelling words, catechism, the Ten Commandments, and verses for religious training. For over one hundred years, in innumerable revised forms, this most famous of all early children's books was the standard beginning text in America. Its rhyming alphabet, which could be recited by almost every child, began:

A—In Adam's fall
We sinned all

And so on, with every letter followed by a religious verse.

Cotton Mather.—Cotton Mather (1663–1728) was best known of the children's writers in early American days. One of his books, first published in 1700, was reprinted for more than fifty years. Its gloomy title was *A Token for the Children of New England, and Some Examples of Children in Whom the Fear of God Was Remarkably Budding When They Died, in Several Parts of New England*. Cotton Mather had fifteen children of his own, but never wrote with tenderness or love, but solely to exhort and terrify.

Children's poetry of the day was of this nature:

I in the burial place may see
Graves shorter far than I;
From death's arrest no age is free,
Young children, too, may die.

Eighteenth Century.—*John Newbery*.—Fortunately for children, England, which had sent to the New World Puritanism and the pious sayings of children who died young, prepared an antidote. In the year 1744, an English publisher, John Newbery (1713–1767), printed a new kind of children's book. It was called *A Little Pretty Pocket-Book Intended for the Instruction and Amusement of Little Master Tommy and Pretty Miss Polly with Two Letters from Jack the Giant Killer*. By 1750, John Newbery was advertising in the *Philadelphia Gazette* a variety of children's books "all in a plain familiar Way

for Youth of Both Sexes." Newbery published close to 200 stories, most of which were devised with an understanding affection for children. Some of them dealt with "useful subjects," such as "eloquence and propriety, the solar system, Rules for Behavior, and the Seven Wonders of the World . . . All interpreted with Letters, Tales, and Fables, for Amusement and Instruction, and illustrated with cuts." But most of Newbery's books were just stories: *Robin Hood*, *Patient Griscl*, the immortal *Guy of Warwick*, and *Reynard the Fox*. For the nursery age, he published *Mother Goose's Melody or Sonnets for the Cradle*. In 1765, he printed *The History of Little Goody Two Shoes*, the authorship of which is attributed to Oliver Goldsmith. This latter book was perhaps the first full-length story written for children with an intent to realism.

Rousseau.—After Newbery's success in the publishing field, it is likely that writers for children would have carried still further the production of books for entertainment and amusement, but a new influence was introduced by French educational reformers. This movement was led by Jean Jacques Rousseau (1712–1778), a French social philosopher, educator, and writer. Rousseau loved nature and its beauties, and was intensely interested in the education of the young. He wrote on education with eloquence and warmth, and in his book *Emile, ou Traite de l'Education*, he outlined a new method of teaching useful knowledge to children. He pictured a child, *Emile*, accompanied always by a wise tutor, receiving his education through his own observations of nature and human activity, and by satisfying his needs for information and character development as situations made demands upon him.

This method of teaching children was carried over into the narrative field by later writers, by having child characters in stories learn by doing: learn of flowers and vegetables by planting and tending them; learn of animals by raising them; learn ciphering by playing at store-keeping and making change; learn self-reliance by being placed in situations that demanded it. The stories became more moralizing, stiff and pedantic, as the idea passed from the more indulgent France to England and America. In England, Thomas Day (1748–1789) was the best of the didactic writers. In his *History of Sandford and Merton*, a story, popular for many years, a clerical tutor trains two boys, one rich and the other poor, using the poor boy as the all-knowing, self-reliant one, and the rich boy as his foil. Maria Edgeworth (1767–1849) was a better writer than Day, but none the less didactic, although she told her moralizing tales with more skill and drama. Her *Parent's Assistant* and *Moral Tales* contained stories that are still included in popular collections.

MODERN PERIOD: 19TH CENTURY

During the 19th century, four separate channels were followed, differing with the national characteristics of peoples. These were: (1) stories of children's activities in contemporary or historical settings, pictured with some attempt at realistic portrayal; (2) picture books for small children produced by gifted artists; (3) national folk lore collected scientifically; (4) a new type of whimsy and fantasy. Because the

nations differed in the fields they pursued, one can only trace the developments in the separate countries which made the most original contributions.

Germany.—In Germany, fairy tale collecting became a science. The Teutonic passion for method and exactness led to a systematic collection and classification, best exemplified in the work of the two brothers Grimm. Jakob Ludwig Karl Grimm (1785–1863) and his brother Wilhelm (1786–1859) became interested in preserving folk lore records for scientific purposes, and to this end they gathered a mass of household tales from the peasantry throughout Germany. For 13 years they amassed a store of old tales before they began to select, to edit, and to publish. Their best-known collection is *Kinder-und-Hausmärchen*, known in English as *Grimm's Fairy Tales*. The Grimms were the first to discover the similarity of folk stories everywhere, and their collections started a national collecting and dispersal of folk literature that is being carried on to the present day.

Switzerland.—Johanna Spyri (1827–1901), living in Switzerland, but writing in German, was inspired at the identical period of Louisa May Alcott in the United States (see below) to write a realistic story of child life that was to remain a beloved classic—*Heidi*. This authentic, sincere story of a little girl in the Swiss mountains, her beloved grandfather and her herd of goats, gave an unforgettable picture of firelight on cabin walls, the sputter of toasting cheese, and the activities of happy childhood.

France.—The French genius for poetry and art expressed itself in delicate little verses for and about children, and in equally delicate illustrations for children's stories. The French artists developed a folio type of book, containing pictures with a single line of text. Narrative writers developed the Rousseau learning-through-experience theme, but one gifted novelist, Hector Malot, turned to realism of the *David Copperfield*, autobiographical variety. His *Nobody's Boy* and *Nobody's Girl* were translated into many languages. Jules Verne (1828–1905), although he did not write for children, struck a new vein of scientific adventure. Beginning with his first popular work *Cinq semaines en ballon*, published in 1863, he anticipated later discoveries in aerial and submarine navigation, and produced pseudo-scientific novels that, in translation, achieved world-wide popularity, notably his *Twenty Thousand Leagues Under the Sea*, *Around the World in Eighty Days*, and *From the Earth to the Moon*.

Denmark.—Denmark produced notable collections, but made its foremost contribution in the work of Hans Christian Andersen (1805–1875) who, at the age of 30, began to write some of the most original and the best adapted fairy tales that children's literature has ever known. He was soon famous over the entire civilized world as the gifted author of *The Ugly Duckling*, *The Dauntless Tin Soldier*, *The Tinder Box*, and *The Emperor's New Clothes*. See FAIRY TALES OF HANS CHRISTIAN ANDERSEN.

Italy.—Italy, following in the tradition of Giovanni Francesco Straparola and Giovanni Basile, pursued the imaginative field, and gave one of the world's most popular stories to children: *Pinocchio*, by "C. Collodi." Collodi, whose real name was Carlo Lorenzini, wrote his

famous story of the mischievous but lovable wooden marionette, after he was an elderly man and had retired from his life's work as editor and government official.

Ireland.—Ireland, long the homeland of the "little people" and the leprechauns, where, even today, many an Irish peasant would swear he could watch the fairies dancing in a moonlit glade if only he cared to chance their displeasure should they catch him peeping, began its collections of earliest Gaelic literature in 1825, when T. Crofton Croker published *Fairy Legends and Traditions of the South of Ireland*. The next important collector was Patrick Kennedy, a Dublin bookseller, who declared that he believed implicitly in fairies, as should every man and child who was willing to take the evidence of his own eyes, and, to prove his point, brought out, between the years 1866 and 1871, three books of currently popular tales. Among the Irish original creators was Frances Browne (1816–1879) whose book, *Granny's Wonderful Chair*, became a classic. To mention all the Irish writers who interested themselves in fairy tales of prime interest to children would be to mention almost all the Irish writers of the 19th century. Padraic Colum, born in 1881 and publishing well into the 20th century, is the most prolific of the talespinners who wrote expressly for children, using ancient as well as Irish themes for his tales. Best known of his books are *A Boy in Eirinn*, *The Children's Homer*, *The Golden Fleece*, *The Island of the Mighty*, and *Peep-Show Man*.

Norway.—Of all the Scandinavian countries, Norway has the most interesting folk stories for children. Trolls skip through the dark woods, and giants stalk the hillsides during the long nights. The two foremost 19th century collectors of Norwegian tales were Peter Asbjørnsen (1812–1885) and Jorgen Moe (1813–1882). Together they published two volumes—*Norwegian Folk Tales* and *Norwegian Fairy Tales and Folk Legends*. These books were translated into English by Sir George Dasent under the titles *Popular Tales from the Norse* and *Tales from the Fjeld*. Later, Gudrun Thorne-Thomsen, who was born in Norway but emigrated to America, made of these stories an outstanding children's book: *East o' the Sun and West o' the Moon*.

Russia.—A great country with a tremendous literature, Russia did not disperse all its children's stories to the outside world as England did. Its most important collector was Alexander Afanasief who, in 1863, published a volume called *Russian Popular Tales*, an enormous collection of 3,000 pages containing 332 stories. Afanasief, who had great literary talent, reveals how closely akin are the European and Slavic tales. His *The Dun Cow* is a variant of *Little One Eye*; *The Bear, the Dog, and the Cat* is like *The Bremen Town Musician*, and *The Miraculous Hen* is the familiar *Hen that Laid the Golden Egg*. In the stories of Afanasief one sees the deep sense of seriousness and social purpose of the Russians. Their children's stories do not appear to be written to amuse, as are the French, nor to instruct, as are the English, or to arouse, as are the American; but to be a social instrument for the creation of a large body of like-minded people. One sees peasants who wrest a bare living from the soil, warring on the wolf, the bear, the fox, and on witches and

devils. No stories from any lands tell of as many witches and devils as do the Russian children's stories. J. A. Khudyakof's collection, called *Great Russian Tales*, was published in 1864, and contained 122 stories. A. A. Erlendvein's, called *Popular Stories*, was published in 1863, containing 41. E. A. Chudinsky's, called *Russian Popular Tales*, contained 31. But the work of these three men is only a repetition and continuation of Afanasief's.

Sweden.—This land takes pride in the children's writer Selma Lagerlöf (1858–1940). Although she did not complete her greatest classic for children, *Nils Holgersson's Wonderful Journey through Sweden*, now known in English as *The Wonderful Adventures of Nils*, until 1907, much of her writing was done in the 19th century. *The Girl from the Marsh Croft* and *Further Adventures of Nils* brought her to permanent fame in children's literature. In 1909 she received the Nobel Prize for literature, and in 1914 she was elected to the Swedish Academy—the first woman so honored. Children's literature was thus given the highest approval as a separate art.

England.—In the 19th century, England diversified its children's literature to a wider extent than any other country. Its chief contributions were in the nonsense verse; a new kind of whimsy and fantasy; and picture books either by artists who collaborated with writers or by artists who possessed the twin talent of writing. Edward Lear's *Book of Nonsense* (1846), verses and pictures designed only to amuse, struck a keynote for the nation. Next in importance came the book that England herself calls her greatest contribution to children's literature—*Alice in Wonderland*, written by Lewis Carroll (pseudonym for Charles Lutwidge Dodgson, 1832–1898). Written to amuse a little girl, Alice, and her sisters, the nonsense of this book so delighted adults and children alike, that Dodgson wrote a sequel *Through the Looking Glass and What Alice Found There*. The two little books were sensationally popular on both sides of the Atlantic, and are still extensively quoted.

England's artists, turning to children's books as a new outlet for their talent, began to illustrate and to write. Great names come from England's 19th century artists—Kate Greenaway: *Apple Pie, Under the Window, Marigold Garden, Mother Goose*; Walter Crane—*Baby's Own Aesop*; Randolph Caldecott—*Come Lassies, Hey Diddle Picture Book*, and others; L. Leslie Brooke—*The Golden Goose Book, The Three Little Pigs, Johnny Crow's Garden, The Tailor and the Crow*; Beatrix Potter—*Peter Rabbit* series.

Although Beatrix Potter's *The Adventures of Peter Rabbit* was to become the most popular of all children's stories for the very young, Randolph Caldecott (1846–1886) possessed perhaps the greatest talent as an illustrator. He published 16 books for children, picturing horses, dogs, activities of children, and scenes of the English countryside. The Caldecott picture books are world classics. The late 19th century led another great artist to England's imposing list: Arthur Rackham (1867–1939). Although Rackham's best-known illustrating was done in the 20th century, he was beginning to be known in the 1890's. Rackham illustrated principally the work of others, preferring the traditional fairy tales for which he painted deli-

cately beautiful pictures in subdued blues, greens, and golden browns, but he published two books under his own name: *Arthur Rackham's Book of Pictures* (1913), and *The Arthur Rackham Fairy Book* (1933).

England's original fairy tales, collections of old tales, and animal stories were voluminous in quantity, and cannot be listed adequately here. Dinah Mulock Craik (1826–1887) wrote the beloved *Little Lamé Prince, The Adventures of a Brownie*, and *The Fairy Book*, although she preferred to be known as the author of *John Halifax, Gentleman*. George MacDonald (1824–1905) wrote *At the Back of the North Wind, The Princess and the Goblin*, and *The Princess and Curdie*. A scholarly antiquarian, James Orchard Halliwell, published in 1842 *Nursery Rhymes of England*, and, later, *Popular Rhymes and Nursery Tales*, two books that later reprinted in one volume called *Nursery Rhymes and Tales* are still basic in the field of jingles and nursery classics. Joseph Jacobs (1854–1916) collected six volumes of fairy tales that had originated in ancient and medieval days. Andrew Lang (1844–1912), the most popular of all English collectors of fairy tales, published close to 100 books, as well as magazine articles. Best known are his fairy tales named for colors—*The Blue Fairy Book, The Red Fairy Book*, and others. Two English writers who lived in both the 19th and 20th centuries belong in this period because of the nature of their work. Kenneth Grahame (1859–1932) wrote only one successful book, but it was outstanding as a talking-beast tale—*The Wind in the Willows*. And combining fantasy with realism came the incomparable Rudyard Kipling (1865–1936), whose tremendous literary output included the children's classics—*Kim, The Jungle Book, Second Jungle Book*, and *Just So Stories*.

The English master of adventure tales in this century was Robert Louis Stevenson (1850–1894), whose *Treasure Island*, and *Kidnapped* (qq.v.) took permanent place as classics. His versatility was further revealed in *A Child's Garden of Verses and Ballads*.

George Alfred Henty (1832–1902), British war correspondent, was a prolific writer of boys' stories that achieved wide popularity in both England and the United States.

England's 19th century writers took high rank in world literature; it was an age of scientific thought and practical reform. Prose and poetry alike were imbued with an ethical purpose, and novelists turned to social problems as their themes. Because of what Dickens called "the romantic aspect of familiar things," a considerable part of the literature designed for adults turned out to have those qualities of vivid expression and swift action that appeal to the young. Therefore, much of the work of England's great novelists became a part of children's literature. Children everywhere were fascinated by the graphic tales which, in the words of Dickens, sought to "banish from earth some few monsters of selfishness, malignity, and hypocrisy, set to rights a few obvious imperfections in the machinery of society, inspire all men with a cheery benevolence . . ." all of which accomplishment would have the effect of making everything "go well with this excellent world of ours." Chief among the 19th century English novelists and poets whose work, in part, was read by children were (listed in order of birth-date,

with 1803): Edward Bulwer-Lytton, Alfred (Lord) Tennyson, William M. Thackeray, Charles Dickens, Charles Reade, Charlotte Brontë, Charles Kingsley, George Eliot, John Ruskin, Jean Ingelow, Thomas Hughes, Wilkie Collins, George MacDonald, R. D. Blackmore, Dinah Maria Mulock, Thomas Hardy, W. H. Hudson, Joseph Conrad, A. Conan Doyle, Sir James Barrie, Rudyard Kipling, Arnold Bennett, John Galsworthy, Walter de la Mare, John Masfield, and Lytton Strachey. It is an imposing list that may be added to by any of the devoted readers of a generation ago. It is debatable whether any other country produced as much entertaining fiction which received world-wide attention through translations as did the English novelists of the 19th century.

United States.—Realism was America's greatest contribution to children's literature in the 19th century, but it entered upon this gradually. Variations of the instruction-through-activity method, as innovated in France by Rousseau, became widely used in stories for children. Samuel G. Goodrich (1793-1860) was the first to combine the method with literary merit. Under the pseudonym of Peter Parley, Goodrich wrote more than a hundred books for young people, picturing children learning geography, history, art, and science by traveling and seeing at first hand the material they were learning.

Jacob Abbott (1803-1879), a leader in education, was the first to use this method in long series form. He wrote the Rollo travel books in 28 volumes, in which Rollo travels through many countries learning by seeing and taking part in the lives of other peoples. His *Franconia* stories ran to 10 volumes. Platitudinous and moralistic though these books may sound to modern readers, they were an advance in children's literature. The domination of the religious and moralistic writers weakened with the publication in 1819 of Washington Irving's *Sketch Book* (q.v.), containing *Rip Van Winkle* and *The Legend of Sleepy Hollow* (q.v.). Irving's genial spirit brought warmth to stories that children craved; they had so long been chilled by moral tales and preaching. Nathaniel Hawthorne (1804-1864), following Irving, combined a poetic spirit with a charming style. His *Grandfather's Chair*, *Biographical Stories for Children*, *The Wonder Book*, and *Tanglewood Tales* (q.v.) were a fresh breeze blowing away a miasma of foggy mediocrity and patronage.

Of the many children's poets, the sisters Jane Taylor (1783-1824) and Ann (1782-1866), and Alice Carey (1820-1871) and her sister Phoebe (1824-1871) were the earliest to become popular. Phoebe Carey's *The Leak in the Dike* is still enjoyed, as is Jane Taylor's *Twinkle, Twinkle, Little Star*. But two greater poets were James Whitcomb Riley (1849-1916) and Eugene Field (1850-1895). Riley was pre-eminent as an interpreter of the simple life in childhood in kindly, homespun verse; of his 14 published volumes, the most popular were *Rhymes of Childhood*, and *A Child World*. Eugene Field was an author and poet of rare sympathy. His *With Trumpet and Drum*, *Poems of Childhood*, and other volumes showed unusual powers of appreciation and understanding.

The two writers who helped turn the stream of children's literature toward realism in the 19th century were not primarily children's writers, although their books were immediately taken

over by older children. These were James Fenimore Cooper and Herman Melville. Cooper (1789-1851) was the first American writer to extend the domain of fiction over the American scene—its great forests and prairies, and surrounding seas. Children found most interest in his *Leatherstocking* series, stories of adventure and of Indian life, including *The Deerslayer*, *The Last of the Mohicans* (qq.v.), *The Pathfinder*, *The Pioneers*, and *The Prairie*. Herman Melville (1818-1891) wrote sea stories: *Moby Dick*, *Typee*, *Omoo* (qq.v.), *Redburn*, *White Jacket*, and *Mardi*, all high adventure tales, well told, in authentic settings.

The first American juvenile writer to devise a new pattern of realism was Louisa May Alcott (1832-1888). Her *Little Women* (q.v.) broke completely from the English and Continental tradition of writing for children and was as American as the ice-cream soda. This simple, believable narrative of the home life of four girls and their parents created, not types of children as such stories as *Little Goody Two-Shoes* had done, but characters who sprang from the pages as real people to bring utter conviction and delight to child readers. Her format was so new that a publisher could not immediately be found who could believe in the success of such a factual, detailed narrative of home activities. *Little Women* was phenomenally successful, and was soon followed by Miss Alcott's *An Old-Fashioned Girl*, *Eight Cousins*, *Silver Pitchers*, *Under the Lilacs*, *Little Men*, *Rose in Bloom*, *Jo's Boys*, and other stories, all of which rank among the most highly esteemed American fiction for young people.

Before Miss Alcott finished her brilliant career, other writers were branching into new fields of realism. Mary Mapes Dodge (1831-1905) editor, poet, and juvenile writer, published *Hans Brinker, or The Silver Skates*, a story that became a beloved classic on both sides of the Atlantic. *The Land of Pluck* and *The Golden Gate* followed, and from 1873, Mrs. Dodge ably edited the juvenile periodical *St. Nicholas*, which, for years, was to carry outstanding verse and prose for children.

Kate Douglas Wiggin (1856-1923) followed in the tradition of Mary Mapes Dodge, producing the widely popular stories—*The Bird's Christmas Carol*, *Mother Carey's Chickens*, and *Rebecca of Sunnybrook Farm*.

Other American women writers of the 19th century and their best-known works were: Jane Andrews, *Each and All*; Eleanor Atkinson, *Greyfriars Bobby*; Jane Goodwin Austin, *Standish of Standish*; Frances Hodgson Burnett, *Little Lord Fauntleroy* (q.v.); Martha Finley (Martha Farquharson), *Elsie Dinmore* series; Lucretia Peabody Hale, *The Peterkin Papers*; Jean Ingelow, *Mopsa the Fairy*; Sarah Orne Jewett, *Betty Leicester*; Margaret Sidney (Lothrop), *Five Little Peppers* series, and Frances Baylor (Barnum), *Juan and Juanita*.

Two writers who used the love story successfully for teen-age girls were: Susan Coolidge (Sarah Chauncey Woolsey), *What Katy Did* series; and Helen Hunt Jackson, *Ramona* (q.v.), two forerunners of a host of writers in a new field of children's stories based on the oldest of all themes.

Men writers of the 19th century turned to adventure, picturing boys in contemporary or historical settings. Best known of these writers

and their books which became most popular were: Thomas Bailey Aldrich: *The Story of a Bad Boy*; James Baldwin, *The Story of Roland*; John Bennett, *Master Skylark*; Eldridge Brooks, *The Master of the Strong Hearts*; Noah Brooks, *The Boy Emigrants*; Edward Eggleston, *The Loosier Schoolboy*; Oliver Optic (William Taylor Adams), *Onward and Upward* series; James Otis (James Otis Kaler), *Toby Tyler*; Thomas Nelson Page, *Two Little Confederates*; Howard Pyle, first of the distinguished artist-authors, *The Merry Adventures of Robin Hood* and other stories; Horace E. Scudder, *George Washington*; and John Trowbridge, *Cudjo's Cave*. Frank R. Stockton, famous as a humorist, created not only realistic stories, but fanciful stories as well.

The series books, which became very popular toward mid-century, were best exemplified in the work of Joseph A. Altsheler (1862-1919) who wrote of various periods in American history: a *Civil War* series, a *French and Indian War* series, the *Young Trailers* series.

Joel Chandler Harris (1848-1908), best of the collectors of southern folk tales, became eminent for his Afro-American studies. His *Uncle Remus* (q.v.) tales, markedly similar to the Hindu *Jatakas*, tied the New World literature to the old as did no other author's.

To round out the 19th century and raise realism to a new height, there appeared, in 1876, Mark Twain's *Adventures of Tom Sawyer*. Mark Twain (Samuel Langhorne Clemens: 1835-1919) American humorist, was more completely realistic than any preceding writer for children; his characters emerged with all the good and bad intermingled that their times made inevitable. Among his many books, all of which became classics, *The Adventures of Huckleberry Finn* (1885) was also high in the esteem of children.

During the second half of the 19th century, a split appeared between books that held widespread popular appeal for children and books that received adult approval. The books listed above happily combined both, but this was not true of many. The work of L. Frank Baum (1856-1919) revealed this split at its widest. Baum wrote *The Wonderful Wizard of Oz* (1900), followed by a long series of Oz books. They sold by the hundred thousands, and for over fifty years led many lists of best-liked books for children 8 to 12 years of age, but adults termed them "fantastical trash."

The Oz books endured in spite of adult disapproval, but the dime novels, first appearing in the summer of 1860, did not endure. These cheap little paper-covered books or pamphlets, dramatized the American pioneers and the opening of the West. The first novel of young Edward S. Ellis, *Señor Jones; or The Captive of the Frontier*, sold, in dime novel format, 600,000 copies, and was translated into a number of foreign languages. Other dime novels dealt with pirates and whalers, hunters, soldiers, and Indians, and with adventure on the prairie. In three years' time, five million dime novels had been sold, and after ten years there was hardly an American boy who did not have a stack of them secreted from parental eyes. When they died of their own unbridled sensationalism, their place was taken by paper-covered series books of youthful achievement. Horatio Alger (1834-1899) wrote 130 books with the rags-to-riches formula—From

Farm Boy to Senator, Joe's Luck, Brave and Bold. Burt L. Standish (Gilbert Patten) wrote 900 stories, all dealing with the school and athletic adventures of a flawless hero, Frank Merriwell, and his brother Dick. Later reprinted three to a volume, these made 208 books, of which 125,000,000 copies were sold. Alger and Patten were the last of a group of prolific writers whose output was unparalleled in quantity, yet so hastily written that not a single story endured. The immediate successor of the paper-covered tale of sports and adventure was a throw-back to the dime novel and the older chap-books. Called the "Comics" because originally they were designed to amuse, and when they first appeared were called "Comic-strips" in newspapers, the 20th-century Comic was (usually) an unbound stitched or pasted pamphlet of pictures with a few lines of explanatory text, often lurid and sensational, dealing with much the same type of fantastic adventure—though in more modern guise—as had brought adult displeasure down upon the publication of the dime novels. More interesting to boys than to girls, they were notably popular with the enlisted men of World Wars I and II. Either because adults have grown more tolerant or more understanding, they have received far less opprobrium than the earlier dime novels; they are sold in vast numbers in drug-stores across the entire United States. In their continued newspaper form, they sometimes achieve a new form of native art that is as much enjoyed by adults as by children.

MODERN PERIOD: 20TH CENTURY

In the first half of the 20th century, two world wars affected the printing trade in Europe. France and Germany produced picture books for small children that were unexcelled in artistry but lagged in books for older children. England, the Lowlands, and the Scandinavian countries were handicapped, sometimes from the simple lack of paper; yet England produced some of the best children's poetry of the first half of the century, along with a few adventure stories that were excellent examples of their type.

United States.—In the United States, the unprecedented industrial expansion made possible the widest diversification in juvenile literature. It was a transition period in the United States, with writers striving to reconcile adult requirements with child interest, and to capture in literary form suitable for children all the new scientific and industrial developments. And beyond these general factors, there were several forces at work that profoundly influenced children's books.

First and most important, there was the growth of the public library and the training of children's librarians. These trained women encouraged the circulation of choice books and discouraged that of the ephemeral and sensational; they created children's rooms that were quiet oases of literary delights.

Second, public schools opened school libraries, as tools of education and included a widely diversified literature, which grew as teachers and librarians learned to coordinate their efforts.

Third, publishers established special children's departments, where editors vied in enticing the best talent into the field.

Fourth, the American Booksellers' Association inaugurated Book Week, designed to display the best books for children. Since 1919, Book Week has been featured annually in the United States,

CALDECOTT PRIZE WINNERS

Year	Artist	Title of book
1938	Dorothy Lathrop	<i>Animals of the Bible</i>
1939	Thomas Handforth	<i>Mai Li</i>
1940	Ingri and Edgar Parin d'Aulaire	<i>Abraham Lincoln</i>
1941	Robert Lawson	<i>They Were Strong and Good</i>
1942	Robert McCloskey	<i>Make Way for Ducklings</i>
1943	Virginia Lee Burton	<i>The Little House</i>
1944	Louis Slobodkin	<i>Many Moons</i> (text by James Thurber)
1945	Elizabeth Orton Jones	<i>Prayer for a Child</i> (text by Rachel Field)
1946	Maud and Miska Petersham	<i>The Rooster Crows</i>
1947	Leonard Weisgard	<i>The Little Island</i> (text by Margaret Wise Brown)
1948	Roger Duvoisin	<i>White Snow, Bright Snow</i> (text by Alvin Treaselt)
1949	Berta and Elmer Hader	<i>Big Snow</i>
1950	Leo Politi	<i>Song of the Swallows</i>
1951	Katherine Milhous	<i>The Egg Tree</i>
1952	Nicolas Mordvinoff (with William Lipkind)	<i>Finders Keepers</i>
1953	Lynd Ward	<i>The Biggest Bear</i>
1954	Ludwig Bemelmans	<i>Madeline's Rescue</i>
1955	Marcia Brown	<i>Cinderella</i>

NEWBERY PRIZE WINNERS

Year	Author	Book
1922	Hendrik Willem van Loon	<i>The Story of Mankind</i>
1923	Hugh Lofting	<i>The Voyages of Dr. Dolittle</i>
1924	Charles Boardman Hawes	<i>The Dark Frigate</i>
1925	Charles Joseph Finger	<i>Tales from Silver Lands</i>
1926	Arthur Bowie Chrisman	<i>Shen of the Sea</i>
1927	Will James	<i>Smoky, the Cowhorse</i>
1928	Dhan Gopal Mukerji	<i>Gay-Nech</i>
1929	Eric P. Kelly	<i>The Trumpeter of Krakow</i>
1930	Rachel Lyman Field	<i>Hitty, Her First Hundred Years</i>
1931	Elizabeth Coatsworth	<i>The Cat Who Went to Heaven</i>
1932	Laura Adams Armer	<i>Waterless Mountain</i>
1933	Elizabeth Foreman Lewis	<i>Young Fu of the Upper Yangtze</i>
1934	Cornelia Lynde Meigs	<i>Invisible Louisa</i>
1935	Monica Shannon	<i>Dobry</i>
1936	Carol Ryrie Brink	<i>Caddy Woodlawn</i>
1937	Ruth Sawyer	<i>Roller Skates</i>
1938	Kate Seredy	<i>The White Stag</i>
1939	Elizabeth Enright	<i>Thimble Summer</i>
1940	James Daugherty	<i>Daniel Boone</i>
1941	Armstrong Sperry	<i>Call It Courage</i>
1942	Walter D. Edmonds	<i>The Matchlock Gun</i>
1943	Elizabeth Janet Gray	<i>Adam of the Road</i>
1944	Esther Forbes	<i>Johnny Tremain</i>
1945	Robert Lawson	<i>Rabbit Hill</i>
1946	Lois Lenski	<i>Strawberry Girl</i>
1947	Carolyn Bailey	<i>Miss Hickory</i>
1948	William Pène duBois	<i>Twenty-One Balloons</i>
1949	Marguerite Henry	<i>King of the Wind</i>
1950	Marguerite de Angeli	<i>Door in the Wall</i>
1951	Elizabeth Yates	<i>Amos Fortune, Free Man</i>
1952	Eleanor Estes	<i>Ginger Pye</i>
1953	Ann Nolan Clark	<i>The Secret of the Andes</i>
1954	Joseph Krumpolt	<i>And Now Miguel</i>
1955	Meindert De Jong	<i>The Wheel on the School</i>

and was followed throughout other countries until, by 1950, twelve separate nations were holding national book weeks.

Finally came the stimulation given by awards for the best children's books. In the United States, this movement began in 1921 when the children's section of the American Librarians' Association voted to award a medal annually to "the most distinguished children's book written by an American author in the preceding year." This medal was called The Newbery Medal in honor of the 18th century English bookseller, John Newbery.

Frederic G. Melcher, who endowed the Newbery Medal, also established and endowed a second medal for the most distinguished American picture book for children published each year. It is called the Caldecott Medal, in honor of the English artist, Randolph Caldecott. Its winners have been artist-authors, or illustrators of others' work.

Canada.—The Canadian Association of Children's Librarians awards a medal for the outstanding children's book by a Canadian author. This medal honors Madame Louis Hébert, wife of the first Canadian farmer, who instructed French and Indian children in her own home.

HEBERT MEDAL WINNERS

Year	Author	Book
1946	Roderick Haig-Brown	<i>Starbuck Valley Wint</i>
1947	No award	
1948	B. Mabel Dunham	<i>Kristli's Trees</i>
1949	R. S. Lambert	<i>Franklin of the Arctic</i>
1950	No award	
1951	Catherine Anthony Clark	<i>The Sun Horse</i>
1952	No award	
1953	No award to an English book; French award: Reverend Emile Gervais	<i>Le Venerable François de Montmorency-Laval</i>

Annual winners of the Governor-General Medal have been:

CANADIAN LITERATURE

Year	Author	Book
1950	R. S. Lambert	<i>Franklin of the Arctic</i>
1951	D. Donald Dickie	<i>The Great Adventure</i>
1952	John F. Hayes	<i>A Land Divided</i>
1953	Marie McPhedran	<i>Cargoes on the Great</i>
1954	John F. Hayes	<i>as We Ride at Night</i>

Twentieth Century Types.—*Nursery Tales and Picture Books*: First place for nursery tales written in the 20th century went to an English woman, Helen Bannerman, for the inimitable *Little Black Sambo*. It took a place with Beatrix Potter's *Peter Rabbit* in the affections of small children, sharing eminence only with the immortal *Three Little Pigs* and Robert Southey's *Goldilocks and the Three Bears*. In picture books, France led all other nations in the picturing of animals in whimsical and comical situations. The *Babar, the Elephant* books, by Jean de Brunhoff, of France, were rated the most novel of the half-century's picture books. Germany was the acknowledged leader in artistry and colors until the wars ended their production. The pictures printed in Germany for Sibylle v. Olfers' *When the Root Children Wake Up* received international acclaim for rare coloring and beauty.

Folk, Fairy, and Nonsense Tales and Talking-Animal Stories.—The national collecting of folklore, accelerated by the work of the brothers Grimm in Germany, spread during the 20th century to every country on the globe. Where national genius did not exist for literary productions, as in Africa, outside writers went in to collect the native folklore. Translations appeared with illustrations to make the stories more appealing to children. To the traditional material, new talking-animal tales and droll tales of nonsense were added. Typical of the best in America for younger children were Margery Bianco's *The Little Wooden Doll*, *Poor Cecco*, and *The Velveteen Rabbit*, and in England were A. A. Milne's *Winnie-the-Pooh* stories. For children a little older, rated high were Hugh Lofting's *Dr. Dolittle* books, Pamela Travers' *Mary Poppins*, and Richard and Florence Atwater's *Mr. Popper's Penguins*.

Legends.—These stories, which in previous centuries, had told of the exaggerated achievements of popular heroes or gods, changed in the 20th century to the tall tale. In the United States, the tall tale swelled into mighty proportions with five regional heroes: Paul Bunyan, the logger; Pecos Bill, from the Western plains; Tony Beaver, from the South; John Henry, the steel-driving man, and Old Stormalong, from the New England coast. More than ten writers made good collections of these tales.

History.—Histories which subordinated dates and wars to accounts of the social and industrial life of the people appeared in the 20th century for juvenile readers. Among the best published in the United States were Virgil Hillyer's *A Child's History of the World*, Hendrik Van Loon's *Story of Mankind*, Ramon Coffman's *Our America*, and Eva March Tappan's *American History Stories*, and *The Story of Our Constitution*. Of far more interest to children, however, were the books of historical fiction. Howard Pyle (1853-1911), the eminent illustrator-author, was the first American writer to perfect this type of writing, notably in *Otto of the Silver Hand* and *Men of Iron*, stories of the medieval period in Europe. Elizabeth Janet Gray followed in his realistic tradition with *Adam of the Road*; Evalene Stein with *Gabriel and the Hour Book*, *A Little Shepherd of Provence*, and *Troubadour Tales*; Katharine Gibson with *Oak Tree House and Jock's Castle*, and Stephen Meader with *Who Rides in the Dark*. Books of American historical fiction became especially numer-

ous; the period of pioneer life gave writers colorful, dramatic material. Some of the best were Cornelia Meigs' *Clearing Weather* and *Master Simon's Garden*; Walter D. Edmonds' *The Matchlock Gun*; Rachel Field's *Calico Bush*; Esther Forbes' *Johnny Tremain*; Carol Ryrie Brink's *Caddy Woodlawn* (a prime favorite); and Laura Ingalls Wilder's *Little House in the Big Woods*.

Biography.—After 1930, biographies increased rapidly in number; within ten years time over 150 good biographies appeared for children, most of them well illustrated and written in lively narrative style. Every type of person was covered by the biographers—statesmen, eminent women, scientists, pioneers, explorers, musicians, artists, writers. A few of the titles, published in the United States, will indicate the scope of these books: *The Romantic Rebel* by Hildegard Hawthorne (the life of Nathaniel Hawthorne), *Nansen* by Anna Hall, *Pasteur* by Francis Benz, *Abe Lincoln Grows Up* by Carl Sandburg, *Daniel Boone* by Stuart White, illustrated by James Daugherty, *Amundsen, the Splendid Norseman* by Bellamy Partridge, *Penn* by Elizabeth Gray, *Young Lafayette* by Jeanette Eaton, *George Washington Carver* by Rackham Holt, *Haym Solomon, Son of Liberty* by Howard Fast, *Drina, England's Young Victoria* by Marion Flexner, *Madame Curie* by Eve Curie, *He Heard America Sing* (the life of Stephen Foster) by Claire Purdy; and *Deep Flowing Brook* (the life of Bach) by Madeleine Goss.

International Themes in Fiction: Stories of children of other lands had been popular in English-speaking countries ever since Mary Mapes Dodge's *Hans Brinker* and Johanna Spyri's *Heidi*. In the 20th century, a growing consciousness of "One World" led to a wider interest in the contemporary life of children in other countries. A few books that illustrate this highly popular trend were: *Poppy Seed Cakes* by Margery Clark (Mary Clark and Margery Quigley), stories with a Russian atmosphere; *Pelle's New Suit* by Elsa Beskow, and *Snipp, Snapp, Snurr and the Red Shoes* by Maj Jan Lindman, both translations from the Swedish; *Young Fu of the Upper Yangtze*, *Ho-Ming: Girl of New China*, *China Quest*, and *When the Typhoon Blows* by Elizabeth Foreman Lewis, pictures of modern China before the Japanese and Communist conquests; *Little Pear and Little Pear and His Friends* by Eleanor Frances Lattimore, artist-author, whose Chinese children are realistically portrayed; *Call It Courage* by Armstrong Sperry, the story of a Polynesian boy; *The Good Master and The Singing Tree*, by Kate Seredy, the adventures of a Hungarian tomboy; and *Dobry* by Monica Shannon, the story of a Bulgarian peasant boy.

Regional Stories.—The different regions of the United States and Canada gave material to writers of the 20th century for stories that dramatized the differences in customs and traditions of separated regions. The *Augustus* books of Le Grand Henderson pictured the poor whites of the South; *Henner's Lydia, Thee, Hannah*, and other books of Marguerite de Angeli were tales of the Amish, Quakers, and Pennsylvania Dutch; *Araminta, Jerome Anthony*, and *Araminta's Goat* by Eva Knox Evans show Negro youngsters; *Waterless Mountain* and *Dark Circle of Branches* by Laura Armer were stories about Navajo Indians; *Chi-Wee* and

Chi-Wee and Loki by Grace and Carl Moon were stories of Pueblo children in their world of desert, mesa, and canyon. Among the regional stories were tales about minority groups, sometimes discriminated against in the social order, which brought social problems into children's literature. These stories told of child life in the Tennessee mountains and the Ozarks, family life among the migratory workers in California, stories of immigrants, and many accounts of Negro-white relationships.

Contemporary Adventure and Achievement: Although the majority of the regional books dealt with child adventure in contemporary settings, there were many adventure and family life stories that were not primarily regional in character. Rated high by librarians were the books of two English authors: Arthur Ransome, who wrote *Swallows and Amazons* and other stories, and Noel Streatfield, who wrote a *Shoes* series (*Ballet Shoes, Tennis Shoes*, etc.). Hilda Van Stockum, who lived in Holland, Ireland, and the United States, wrote four highly rated books about family life in the three countries: *The Cottage at Bantry Bay, Francie on the Run, Pegeen*, and *The Mitchells*. Of the American writers, Eleanor Estes achieved rare humor in the *Moffatt* stories. Elizabeth Enright, who won the Newbery Medal for *Thimble Summer*, a story of family life, wrote *The Saturdays, The Four Story Mistake*, and *Then There Were Five*, all family life adventures.

Stories of the achievements of girls in the professions and businesses were a 20th century innovation indicative of the changing social order. *Sue Barton, Student Nurse* and *Sue Barton, Senior Nurse* by H. D. Boylston were significantly popular with adolescent girls, as was *Peggy Covers the News* by Emma Bugbee. Alice Dalgliesh's *Silver Pencil* was also in this field—one in which writers lagged behind the reading demands of the times.

Animal Fiction.—Writers of animal stories in the 20th century turned from talking-beasts to the realistic portrayal of animal life in authentic settings. For small children, there were picture book animal stories, such as the *Angus* books and *Ping* by Marjorie Flack; *Mittens*, and other stories, by Clare Turlay; *Chuckle and Sniffy, the Story of a Skunk* by David M. Stearns; *Buttons* by Tom Robinson; *The Smallest Puppy* by Margaret Johnson and Helen Lossing; *The Skittle Skattle Monkey* by Dorothy Lathrop; and *Make Way for Ducklings* by Robert McCloskey. For children a little older and for the teen age, among the best-liked were: the *Blaze* stories by C. W. Anderson, who also wrote *Salute, High Courage*, and two biographies of great race horses; *Smoky, the Cow-Horse* by Will James; *Justin Morgan Had a Horse* by Marguerite Henry; *My Friend Flicka, Thunderhead*, and *Green Grass of Wyoming* by Mary O'Hara (Mary Sture-Vasa); *Lassie Come Home* by Eric Knight; the 9 animal stories of Clarence Hawkes, including *Redcoat, the Phantom Fox* and *King of the Flying Sledge*; *Watchers of the Trails* and other works, by Charles G. D. Roberts; *On Safari* and *The White Panther* by Theodore Waldeck; *The Yearling* by Marjorie Kinnan Rawlings; *Kari* by Dhan Gopal Mukerji; and, most popular of all with boy readers: *Silver Chief, Dog of the North* and *Silver Chief to the Rescue* by Jack O'Brien. Many animal-story writers owed a debt to Jack

London (1876–1916) whose *Call of the Wild* (q.v.) formed a much-used pattern of realistic animal adventure.

Natural Science.—The 20th century produced factual books on mammals, amphibians, reptiles, birds, insects, and the stars written in such style that older children, whose interests lay in those fields, could read and enjoy them. Recommended by librarians were William T. Hornaday's books on zoology, particularly *The American Natural History*; Raymond L. Ditmars' studies of reptiles and prehistoric animals; A. B. and J. H. Comstock's works on butterflies and insects; Jean Henri Fabre's narrative accounts of the insect world; Olive Thorne Miller's *Children's Book of Birds*; and G. E. Mitton's *The Book of Stars for Young People*.

Physical Science.—The first half of the 20th century saw scientific discoveries in physics, mechanics, and engineering in such quantity that literature lagged behind discovery. The splitting of the atom split the physical sciences as they were known and taught, and no listing of authors or subjects in this field can have significance until the ferment of discovery settles, and the physical sciences may become reasonable subjects for juvenile writers.

Poetry.—In the 20th century, England produced the two most widely read children's poets. Walter De la Mare was foremost. His *Songs of Childhood*, published in 1902, and his later volumes, *Peacock Pie* and *A Child's Day*, were lilting verses, whimsical and delicate, that were rare in beauty and rhythm. A. A. Milne wrote *When We Were Very Young* and *Now We Are Six*, two small books of comic, imaginative, and musical verses which went through more editions in less time than did any other books of children's poetry ever printed.

Encyclopedias.—Children's encyclopedias, which contain information on all phases of the arts and sciences, were improved to a high degree of completeness and authenticity in the 20th century. The most widely used were *The Book of Knowledge*, *The World Book*, and *Compton's Pictured Encyclopedia*.

A GROWING LIBRARY FOR THE CHILD

(Suggestions to parents)

No adult can predict accurately the exact age at which every child will enjoy a given book. Reading interests of children vary with sex, reading background, environment, individual differences in aptitudes, and intelligence. A parent may only add selected books to the child's bookshelves and let the child enjoy them when he will. As the library is a permanent possession it does not greatly matter when the different books are first appreciated. That is one of the advantages of a child's owning his own books; he has them when he is ready for them, and they become a part of childhood whether first read at 7 or at 12. *Peter Rabbit*, *The Three Bears*, *Little Black Sambo*, and their kindred immortals may be read to the child of 3, retold to him by his first-grade teacher, read by himself at 7, and re-read thereafter throughout life.

THE FIRST BOOKS

Mother Goose Nursery Rhymes and Jingles. There are The perfect First Book for every child. There are many good editions. The parent should choose one with a high quality of paper and binding and with appealing illustrations in color. *Little Mother Goose*, illustrated by Jessie Wilcox Smith; *Gay Mother Goose*, illustrated by Gustav Tenggren; *Mother Goose*; *Seventy*

seven Verses with Pictures by Taasha Tudor; *Ring o' Roses*, illustrated by L. Leslie Brooke are all outstanding collections, beautifully illustrated.

Animal Picture Book, in color.

There are many on the market, variously titled "Our Farm Friends," "Our Pets," and the like. The important thing is that the book (preferably printed on soft linen paper that the littlest children can handle) should contain pictures of the first animals that the child recognizes: the dog, the cat, the horse, the cow. There need be no text, except the name of the animal.

FOR AGES 2 THROUGH 6

These are "read-aloud" stories and picture books, which the adult introduces to the child first through reading them to him, and that the child later learns to read for himself. They will then be re-read up through eight years of age and older.

Animals Everywhere, by Ingri and Edgar Parin d'Aulaire
Ola, by Ingri and Edgar Parin d'Aulaire
Little Black Sambo, by Helen Bannerman
Hans, by Ludwig Bemelmans
Pelle's New Suit, by Elsa Beskow
The Velvetten Rabbit, by Margery Bianco
Five Chinese Brothers, by Claire Bishop
Golden Goose Book, by L. Leslie Brooke
Johnny Crow's Garden, by L. Leslie Brooke
Three Little Pigs, by L. Leslie Brooke (illustrator)
Stone Soup; an Old Tale, by Marcia Brown
Little House, by Virginia Lee Burton
Hey Diddle Diddle Picture Book, by Randolph Caldecott
Puppy Seed Cakes, by Mary Clark and Margery Quigley
Down, Down the Mountain, by Ellis Credle
A B C Book, by Charles Falls
Angus and the Ducks, by Marjorie Flack
Story about Ping, by Marjorie Flack
Millions of Cats, by Wanda Gág
500 Hats of Bartholomew Cubbins, by Geisel, Theodor S. (Dr. Seuss, pseud.)
Little Toot, by Hardie Gramatky
The Big Snow, by Berta and Elmer Hader
Cock-a-Doyle-Do, by Berta and Elmer Hader
Three Blind Mice, by John William Ivey
Animals of the Bible, by Dorothy Lathrop

or

Who Goes There?, by Dorothy Lathrop
Cock, the Mouse and the Little Red Hen, by Felicité Lefevre
Little Train (or Little Auto), by Lois Lenski
Make Way for Ducklings, by Robert McCloskey
Mittens, by Clare Newberry
When the Root Children Wake Up, by Sibylle V. Olfers
The Christ Child, by Maud and Miska Petersham
The Tale of Peter Rabbit, by Beatrix Potter
Buttons, by Tom Robinson and Peggy Bacon
Chicken World, by E. Royd Smith
The Story of the Three Bears, by Robert Southey
 (This popular nursery tale comes in many editions, usually listed under the name of the illustrating artist)
Koroo the Kangaroo, by Kurt Wiese
The Gingerbread Boy (Old Folk Tale)
 (Sometimes called *The Gingerbread Man* or *The Pancake*)

For other familiar nursery tales for reading aloud, parents will find *The Children's Book* by Horace Scudder a discriminating anthology.

FOR AGES 7 THROUGH 11

Between the ages of seven and eleven, the child's reading interests change rapidly. At seven, the average child still prefers animal picture books; by nine he (more often she) prefers the fairy tales; and by eleven, both boys and girls are starting to read realistic stories of child life and adventure that will engage their attention until their adult interests develop. Parents will know from their own child's development which books from the following list should be selected for the different ages. *Babar*, an exceptionally fine picture book from France, is often enjoyed by children as young as four years; it is usually recommended for children of seven; and it is often given to children of ten. Such realistic stories as *Heidi*, *The Saturdays*, or *The Moffats*, on the other hand, are seldom fully enjoyed until ten years of age and later.

Aesop's Fables, by Aesop and others

These classic stories may be bought in many editions; the one edited by Joseph Jacobs is good. Not all of the fables attributed to the Greek slave, Aesop, originated with him; centuries of retelling have confused authorship—but this is not important to the child reader.

Andersen's Fairy Tales, by Hans Christian Andersen
Forest Pool (ages 10-13), by Laura Armer
Seven Simeons; a Russian Tale, by Boris Artzybasheff
Mr. Popper's Penguins, by Richard and Florence Atwater
In the Days of Giants (Norse Tales), by Abbie Farwell Brown

Alice in Wonderland, by Lewis Carroll (pseud.)
Through the Looking Glass, by Lewis Carroll (pseud.)
Picture Tales from the Russian, by Valery Carrick
Henner's Lydia (10 and over), by Marguerite de Angeli
Babar, by Jean de Brunhoff
Peacock Pie, by Walter de la Mare
Red Folk and Wild Folk, by E. W. Deming
The Saturdays (age 10 and over), by Elizabeth Enright
The Moffats (10 and over), by Eleanor Estes
Poems of Childhood, by Eugene Field
Wind in the Willows, by Kenneth Grahame
House in the Woods and Other Fairy Tales, by J. L. K. and W. K. Grimm
 (There are many fine, illustrated editions of Grimm's *Fairy Tales*)

Mei Li, by Thomas Handforth
Uncle Remus Tales, by Joel Chandler Harris
Augustus and the River (age 9 up), by Le Grand Henderson
English Fairy Tales, by Joseph Jacobs
Jungle Book, by Rudyard Kipling
Just So Stories, by Rudyard Kipling
Wonderful Adventures of Nils, by Selma Lagerlöf
Fairy Book collections (any or all), by Andrew Lang
Little Pear, by Eleanor Lattimore
Rabbit Hill, by Robert Lawson
Strawberry Girl, by Lois Lenski
Story of Dr. Dolittle, by Hugh Lofting
Adventures of Pinocchio, by Lorenzini, Carlo (C. Collodi, pseud.)
Homer Price, by Robert McCloskey
Winnie-the-Pooh (for ages 5-10), by A. A. Milne
Chi-Wee, by Grace and Carl Moon
Holiday Pond, by Edith Patch
Heidi, by Johanna Spyri
East o' the Sun and West o' the Moon, by Gudrud Thorne-Thomsen
Many Moons, by James Thurber
Ake's Ten, by Sjoukje Troelstra
Little House in the Big Woods, by Laura Wilder
Johnny Blossom, by Dikken Zwilgmeyer

FOR AGE 12 AND OLDER

After twelve years of age, sex differences in reading interests become more pronounced. Girls, sometimes maturing two years ahead of boys, may dip into adult fiction, and both girls and boys are ready to sample every known variety of book: biographies, historical narratives, social problems, tales of high adventure and mystery. Girls will read boys' books, but boys seldom care for girls' books. The following list gives a sampling of the classics and the modern tales that have been selected by young adolescents as both enjoyable and educational.

Little Women (for girls), by Louisa May Alcott
Lisbeth Longfrock, by Hans Aanrud
Master Skylark, by John Bennett
Caddie Woodlawn (ages 10-15), by Carol Ryrie Brink
Don Quixote (Barrett or Parry Edition), by Miguel de Cervantes
Odyssey for Boys and Girls, by Alfred Church
Aeneid for Boys and Girls, by Alfred Church
Adventures of Tom Sawyer, by Samuel Clemens (Mark Twain)
Understanding Science, by William Crouse
Silver Pencil (for girls), by Alice Dalgliesh
Daniel Boone, by James Daugherty
The Door in the Wall, by Marguerite de Angeli
Robinson Crusoe, by Daniel Defoe
Christmas Carol, by Charles Dickens
Hans Brinker (ages 9-14), by Mary Mapes Dodge
Leader by Destiny (George Washington), by Jeanette Eaton
That Lively Man, Ben Franklin, by Jeanette Eaton
Matchlock Gun (ages 10-15), by Walter D. Edmonds
Calico Bush, by Rachel Field
One God: The Ways We Worship Him, by Florence Marv Fitch
Johnny Tremain, by Esther Forbes
Abraham Lincoln's World, by Genevieve Foster

Goldsmith of Florence, by Katherine Gibson
Adam of the Road, by Elizabeth Janet Gray
Rolling Wheels, by Katherine Grey
Dark Frigate, by Charles Boardman Hawes
Justin Morgan Had a Horse, by Marguerite Henry
The Singing Sword, by Mark Powell Hyde
Rip Van Winkle, by Washington Irving
Ramona, by Helen Hunt Jackson
Smoky, the Cowhorse, by Will James
Safari, by Martin Johnson
Lassie Come Home, by Eric Knight
Franklin of the Arctic, by Richard S. Lambert
Young Fu of the Upper Yangtze, by Elizabeth Foreman Lewis
Call of the Wild, by Jack London
Trap-lines North, by Stephen Meader
Willow Whistle, by Cornelia Meigs
The Year Without a Summer, by Ethel Parton
King Arthur and His Knights, by Howard Pyle
Men of Iron, by Howard Pyle
Merry Adventures of Robin Hood, by Howard Pyle
Swallows and Amazons, by Arthur Ransome
The Yearling, by Marjorie Kinnan Rawlings
Hoof and Claw, by Charles G. D. Roberts
Jinglebob (Cowboy adventure), by Philip Ashton Rollins
Bambi, by Felix Salten
Abe Lincoln Grows Up, by Carl Sandberg
The Good Master, by Kate Seredy
The Great Heritage, by Katherine Binney Shippen
Downright Dencey (for girls), by Caroline Dale Snedeker
Call it Courage, by Armstrong Sperry
Hunters of the Great North, by Vilhjalmur Stefansson
Treasure Island, by Robert Louis Stevenson
Ballet Shoes, by Noel Streatfeild
The Mitchells, by Hilda Van Stockum
Treks Across the Veldt, by Theodore J. Waldeck
Lost Worlds; Adventures in Archaeology, by Anne Terry White
Swiss Family Robinson, Johann David Wyss
They Loved to Laugh, Kathryn Worth

After 14 years of age, many children show a decline in reading interest. The tempo of life has quickened; hobbies have developed; high school activities absorb interest. Moreover, individual differences in 'teen-agers widen with the years. One 15-year old may read adventure tales with enjoyment, but another may want only books on chemistry or science, and a third may be tempted only by historical narratives. The parents' duty in selecting a child's library is largely completed by the time the child has reached 14. After this age, the discriminating reader whose interests have matured normally will want to select the majority of his own books, but his childhood library will remain a prized possession, re-read throughout his youthful and adult years.

MARGARET LIMA NORGAARD,
 Coauthor, "Children's Reading."

CHILDREN'S LITERATURE, Canadian.—The first Canadian story-book written expressly for children was *Canadian Crusoes* by Catherine Parr Traill, published in 1850. Mrs. Traill (1802-1899), who emigrated to Canada from England with her soldier-husband, wrote the story to tell English children about pioneer life in Canada. Two years later, in 1852, Mrs. Traill's sister, Susanna Moodie (1803-1855), also an emigrant from England, published in book-form *Roughing It in the Bush*, which had previously appeared in a Canadian periodical. Both books were first published in England.

The reasons for Canada's late entry into the children's book field are contained in her history, geography, and economic development. Canada is made up of two racial groups, English and French, divided by language and religion, and without sufficient population in either group to support a publishing industry comparable to that in England, France, and the United States. Therefore, many of Canada's authors have sought publishers—and consequently residence

with eventual citizenship—in those countries where they could find a wider market for their writing.

After Canada's entry into World War I, an aroused national consciousness and pride caused Canadian authors to hold more tenaciously to their own country as a source of literary inspiration. Canada's rugged mountains, sea-swept coastline, historic Hudson Bay region, gentle Acadian valleys, pine-scented forests, and prairie villages awakened a regional literature which librarians, educators, and government fostered, and which caused Canadian publishing houses to grow. With this maturing, there developed a distinguished children's literature, illustrated by Canadian artists, which was truly Canadian in material and treatment. Moreover, wherever its place of publication, Canada began to lay vigorous claim, and rightly, to the output of her native sons and daughters, particularly when the material dealt with Canadian scenes, as much of her modern children's literature does.

To Canada goes the honor of contributing a new pattern to children's stories: a realistic animal story based on natural history and animal psychology. Credit is given to Charles G. D. Roberts (1860-1943) for perfecting the animal tale as an important literary form. His book-length animal stories, the first of which was published in 1896, became world models. Other Canadian writers, preceding Roberts, had used an animal as the central character for a book-length narrative, but had produced work of inferior literary merit, or had oversentimentalized, as did M. Marshall Saunders, a Toronto author, who, in 1900, published *Beautiful Joe*, a dog story that was widely popular and which is still read. In 1898, Ernest Thompson Seton, second only to Roberts in skill as a writer, published *Wild Animals I Have Known* from material collected while he was a government naturalist in Manitoba. Seton produced many distinguished animal stories thereafter. In 1900, William A. Fraser published *Mooswa, and Others of the Boundaries*, a story in the Roberts and Seton tradition. And Grey Owl (Wa-Sha-Quon-Asin), a Canadian naturalist who claimed to be a half-breed Indian born in the United States but who was accused of being a masquerading Englishman, wrote at this same period on wild life and woodcraft. Canadian writers, at the beginning of the century were leading all others in animal and nature stories.

Much history and historical fiction has been written for Canadian children, but the delicately descriptive nature poetry for which Canada's writers are famous, has been directed mostly toward adults.

The mid-20th century trend in Canadian children's literature, as in the United States, has been in the writing of regional stories. *Starbuck Valley Winter* by Roderick Haig-Brown, 1946 winner of the Hébert Medal given by the Canadian Association of Children's Librarians for the outstanding children's book, deals with trappers in British Columbia. *Kristli's Trees* by B. Mabel Dunham, 1948 winner, deals with the Amish and Pennsylvania Dutch settlers in Ontario. Other regional stories of Canada will be found in the booklist following.

In 1946, impetus was given to the production of children's books in Canada by the awarding of special citations and medals. The Canadian Association of Children's Librarians awards a

medal for the outstanding children's book by a Canadian author, with the proviso that it must be published in Canada; and a special citation may be given by the Award Committee for the Governor-General's Medal. See CHILDREN'S LITERATURE for special award winners in Canada.

CHILDREN'S BOOKS BY CANADIAN AUTHORS*

(Published in Canada, England, and the United States)

Ballantyne, Robert Michael. *The Dog Crusoe and His Master* (1860), *Ungava* (1857), *The Young Fur Traders* (1856). Ballantyne, a clerk with the Hudson Bay Fur Company, used his experiences as a basis for adventure tales still read and enjoyed.

Bennett, Ethel Hume. *Camp Ken-Jockey, Judy of York Hill, A Treasure Ship of Old Quebec*. Mrs. Bennett, once a teacher in a Toronto girls' school, wrote conventional girls' adventure stories, but with some poetic feeling, typical of Canadian writers, and with typical Canadian appreciation of natural beauties.

Bice, Clare. *Across Canada, Jory's Cove*. Mr. Bice, a distinguished Canadian artist, illustrated his books with his own water colors; and the United States publisher, Macmillan, gave them an attractive format.

Brown, George W. *The Story of Canada*. Co-authorship: George Brown, Eleanor Harman, Marsh Jeanneret. One of the best of the illustrated books published in Canada (Copp Clark, 1949).

Callaghan, Morley. *Luke Baldwin's Vow*. Morley Callaghan, one of the best-known Canadian novelists and short-story writers, wrote little for children except this one book, but many of his short stories appeal to older children. Mr. Callaghan is typical of the many gifted Canadian writers who are counted native of the United States because their work is published there.

Clay, Charles. *Fur Trade Apprentice, Young Voyageur*. Historical narratives of the fur-trading days around 1775, written by a former teacher in an Indian school on James Bay. Mr. Clay, a Canadian journalist, published his books in England.

Connor, Ralph (see Gordon, Charles).

Cory, Harper. *The Bears of Jasper*. Mr. Cory wrote several factual books about mountain animals.

Daveluy, Marie-Claire. *Sur les ailes de l'Oiseau Bleu. Une révolte au pays des fées*. Fairy tales by a French-Canadian author. This writer has also published six little adventure stories of early days in French-Canada. These are not important works, but are typical of French-Canadian publications: imaginative and with an Old-World flavor.

Denison, Muriel. *Susannah, a Little Girl with the Mountains*. One of a series of books about an adventurous Canadian girl.

Destrois, Mme. Antoinette Tardif (Michelle le Normand, pseud.). *Autour de la maison. La plus belle chose du monde*. Two French-Canadian stories typical of the style and format found in many Quebec publications.

Dickie, Donald J. *Dent's Canadian History Readers* (8 vols. Dent). Together with the author's later book, *The Great Adventure* (1950), the 8-volume histories make good source material, but they are not in format that appeals to children.

Dunham, B. Mabel. *Kristli's Trees*. The C. A. C. L. medal winner for 1949. Miss Dunham's *The Trail of the Conestoga and Grand River* are also rated high by Canadian librarians, but not for children.

Evans, Hubert. *North to the Unknown*. A biography of David Thompson who explored and charted Canada's Northwest. Mr. Evans, an Ontario writer, was a government fish conservationist.

Fraser, William A. *Mooswa*. An animal story popular with Canada's children for half a century.

Garvin, John W. *Canadian Verse for Boys and Girls*. An anthology with biographical notes about each poet.

Gordon, Charles William (Ralph Connor, pseud.). *Glen-garry School Days*. The Rev. Charles Gordon, born in Ontario in 1860, wrote extensively of pioneer life in western Canada. Among his other books also popular with children, although not written for them, were: *Black Rock, The Sky Pilot, The Prospector, The Doctor, and The Man from Glen-garry*.

Grey Owl (Wa-Sha-Quon-Asin). *Sajo and her Beaver People. Tales of an Empty Cabin*. Grey Owl, a Canadian by adoption, wrote extensively on wild life, but *Sajo* is his most popular book with children.

Guillet, Edwin C. *Pioneer Arts and Crafts, Pioneer Life, Pioneer Settlements, Pioneer Travel, Finding New Homes in Canada*. Detailed and illustrated books of historical information, written by a Toronto teacher-historian.

Haig-Brown, Roderick L. *Saltwater Summer, Starbuck*

Valley Winter. Two of the best of the Canadian adventure stories for boys. The first received a special Authors' citation; the second the C. A. C. L. medal for 1946.

Hambleton, Jack. *Forest Ranger, Young Bush Pilot. Abitibi Adventure*. Adventure tales of the forestry service and pulp paper industry, by a Canadian journalist and radio-broadcaster.

Hayes, John F. *Buckskin Colonist, Treason at York*. Historical fiction, by a Toronto businessman-artist.

Hébert, Jacques. *Autour des trois Amériques*. A Montreal publication, in French—a factual account of an overland trip of four young French-Canadians who crossed the American continent.

Heming, Arthur. *The Living Forest, The Drama of the Forests*. Mr. Heming, an outstanding artist, based his two self-illustrated books on his experiences in the Canadian woods while in search of material for his paintings.

Hémon, Louis. *Maria Chapdelaine*, translated by W. H. Blake, illustrated by Thoreau Macdonald. This is a Canadian classic, perhaps the foremost, but more suited to the mature reader than to children. Louis Hémon was a French emigré.

Hooke, Hilda Mary. *Thunder in the Mountains*. Legends and stories from pioneer Canadian days and from Indian tribes, and Eskimos. Mrs. Hooke, born in England, has lived most of her life in Ontario.

Jefferys, Charles. *Canada's Past in Pictures*. Jefferys, an artist-historian, has been called "the foremost authority on Canadian history as it concerns life and customs."

Johnson, E. Pauline. *Legends of Vancouver, Flint and Feather*. Miss Johnson, a distinguished poet, had an Indian father and an English mother. Her Indian name was Takahionwake (Double Canoe). There is a memorial cairn to her memory on Siwash Rock in Vancouver.

Kirby, William. *The Golden Dog*. The first important Canadian novel (1877) using the romantic material of early Quebec.

Lambert, Richard S. *The Adventure of Canadian Painting. Franklin of the Arctic*. The first book contains biographies of Canadian artists, with color reproductions of their work; the second, an historical narrative, received the 1949 medal of the C. A. C. L. as the most distinguished book published in Canada by a Canadian author, for boys and girls; and it also received the Governor-General's medal, the first time awarded to a children's book.

Laut, Agnes C. *Lords of the North, Pathfinders of the West*. Heroic adventures in the early days of the Hudson Bay and North-West Companies. Miss Laut, a Manitoba author, writes of the Selkirk settlers.

Locke, George H. *When Canada was New France*. Dr. Locke, a librarian, collected stories of the French regime in Canada.

McCowan, Dan. *Animals of the Canadian Rockies*, illus. by photographs.

Macmillan, Cyrus. *Canadian Fairy Tales. Canadian Wonder Tales*. Cyrus Macmillan, one-time Dean and Professor of English at McGill University, Montreal, made, in these books, two of the best collections of Canadian folk-tales.

Maillet, Andrée. *Le marquiset têtû. Ristontac*. Two short Montreal publications of exceptional merit, particularly *Ristontac*, the legendary tale of a little Indian.

Montgomery, Lucy Maud (Mrs. Ewen Macdonald). *Anne of Green Gables*. Published in 1908, *Anne of Green Gables* and its successor, *Anne of Avonlea* achieved exceptional popularity with girl readers of many countries. It was widely translated and is still stocked by libraries. Mrs. Macdonald, the wife of a clergyman, wrote other books for girls, but none achieved the fame of the *Anne* books.

Moodie, Susanna. *Roughing it in the Bush*. One of the earliest Canadian stories for children. Mrs. Moodie, born in England in 1803, came to Canada in 1832 with her Army husband. She wrote many books, but *Roughing it in the Bush*, first published in book form in 1852, was the only one to endure. The book was first published in the *Literary Garland*, an early Canadian periodical.

Parker, Sir Gilbert. *The Seats of the Mighty*. An historical narrative. Gilbert Parker, commonly considered an English novelist, was born in Ontario in 1862, and did not leave for England until 1889. It was in England that he did much of his writing, and there he entered politics and was knighted. *The Seats of the Mighty*, published in 1896, is a story of Quebec at the time of Montcalm.

Riley, Louise. *Mystery Horse*. A ranch story with a setting in the Alberta foothills, written by a Canadian librarian.

Roberts, Sir Charles George Douglas. *The Feet of the Furtive, Forest Folk, Kings in Exile, Red Fox, Thirteen Bears, Wisdom of the Wilderness, Hoof and Claw*. These are the best-liked of Roberts' many books on animal life. They are, perhaps, the most significant of

* Approved by Canadian librarians.

all Canadian children's books because they ushered in a new technique: the realistic animal story. Charles Roberts, born at Douglas, New Brunswick, in 1861, was professor of English in King's College, Windsor, N. S. from 1885 to 1895, when he resigned to devote himself to literature. He was a highly imaginative and artistic poet, and his nature poetry is still considered among Canada's best. His animal stories were masterpieces, but his novels dealing with human beings were not so successful. He published 67 books, with three others in preparation at the time of his death. He died in 1943.

Saunders, M. Marshall. *Beautiful Joe*. A sentimental story, written in 1900 to teach kindness to animals. Tremendously popular in its day, it had a wide-reaching influence. *Jimmy Goldcoat*, *My Pets*, and other stories by this author, were less popular.

Seton, Ernest Thompson. *Bannertail, The Biography of a Grizzly*, *The Biography of a Silver Fox*, *The Biography of an Arctic Fox*, *Lives of the Hunted*, *Monarch*, *The Big Bear of Tallac*, *The Trail of the Sandhill Star*, *Wild Animals at Home*, *Wild Animals I Have Known*. Only the chance that Charles G. D. Roberts was a contemporary in Canadian letters prevented Ernest Thompson Seton from being Canada's greatest writer of animal tales. Born at South Shields, England, in 1861, Seton spent his childhood in the forests of Canada and on the western plains. He became official naturalist to the government of Manitoba, and published *Mammals of Manitoba* and *Birds of Manitoba*. An artist as well as a writer, he illustrated much of his own work. Besides his animal stories, he wrote *Two Little Savages*, a somewhat autobiographical story, and *Rolf in the Woods*, which, like his other books, showed his knowledge of camping, hunting, trapping, and animal life. He also wrote manuals of woodcraft and Indian lore.

Skinner, Constance Lindsay. *Beaver, Kings, and Cabins*. Constance Skinner, born in British Columbia at a Hudson Bay trading post, has many novels, poems, and popular juvenile books to her credit. She is now a resident of the United States, where she edited a series called *Rivers of America*, and wrote the volume on the *Missouri*.

Sullivan, Edward Alan. *Brother Blackfoot*, *Brother Eskimo*. Mr. Sullivan, an engineer by profession, an explorer by avocation, gives details of life with the Indians and the people of the Polar regions.

Tait, George E. *The Silent Gulls*. Mr. Tait, an educator, uses the Great Lakes shore life as the theme for this book.

Traill, Catherine Parr. *Canadian Crusoes*. This book, one of the earliest written in Canada for children, was first published in England in 1852; it was republished in Toronto in 1855 under the title: *Lost in the Backwoods: the Female Emigrant's Guide*. In 1923, it was reprinted by McClelland and Stewart, and is still read by Canada's children. Mrs. Traill, a sister to Susanna Moodie (see above), was a botanist and her *Studies in Plant Life in Canada* has also remained on Canadian library shelves. Besides Mrs. Traill and Mrs. Moodie, there was a third writing sister left behind in England when the first two emigrated to Canada with their Army husbands and thereafter adopted Canada as their home. They were all three exceptional women.

Woodley, Edward Carruthers. *Legends of French Canada*. Mr. Woodley, a Montreal churchman and educator, has added to a field that is still open for Canadian folklorists.

MARGARET LIMA NORGAARD,
Coauthor "Children's Reading."

CHILDREN'S PLAYGROUNDS. — RECREATION CENTERS.

CHILDREN'S THEATER. A widespread consciousness of the importance of make-believe in the development of children has gathered tremendous impetus since the turn of the century, and has led to an equally widespread activity in the production of plays by and for children. However, the movement has remained chaotic and unintegrated as regards incentives, ideals, forms, financing, and relations to social and educational thinking.

The children's theater movement is rooted in the inborn desire of children to explore the world about them. As spontaneously as they use taste and touch, children resort to the dramatic imitation of things, animals, people, and situations.

This activity in children has all the urgency of growth, and its satisfactions give corresponding keen delight. Every culture, accordingly, inevitably develops imaginative forms of it: drama, toys, games, rituals, dances, pantomimes, puppetry, pageantry, plays, and theater.

Throughout history two incentives have been influential in shaping these forms. Certain interests seek to use them for their own advantage; others, for the education of children. China, for example, traveling showmen have made a living for centuries by giving street shows for children, who gather at the sound of drum or gong. The troupe often consists of the showman and two boys and a monkey, or a juggler with two or three acrobats. The fact that expenses are met by passing the hat, or charging the small fee that children can pay has conditioned the quality of such entertainment in China, and has almost eliminated the on popular street shows in many other lands at times. The same thing is true of puppetry which flourished all over the Orient after 1,000 B.C., spreading from Egypt to Greece and Rome from Rome to all Italy, and, early in the 17th century, from Italy to all Europe. A 20th century resurgence of interest in puppet theaters for children faced the same problem common to other plays for children, that of combining profit with high quality.

This problem was solved for a time by Shakespeare's day by the master of a boy company which played for two years at the Blackfriars theater in London. The talented and highly trained young actors of this company were unpaid, and their costumes and keep were provided by the court until it was charged that the master, for his own gain, was exhibiting boys "taken" (that is, impressed or kidnapped by royal order for the queen's revels, after which performances were discontinued). However, it is not always for profit that adults exploit the inborn power of children to act. Queen Elizabeth's order to "all mayors, sheriffs, bayliefs, constables, and other officers," enjoining them to observe it "to the uttermost of your powers, as ye will answer to the uttermost of your perylls," stated explicitly that when her agent "takes" any boy, he is to be used in court revels for her "solace." In many other lands and times, children have continued to be dressed and drilled in shows which mean nothing to them except a chance to show off, not for the solace of a queen, but for the pleasure and pride of teacher or parents, or for the benefit of this or that adult interest.

Consciousness of the educational values of dramatic experience by children is as old as the desire to exploit it. Primitive folk have always used dramatic ritual to teach adolescents. In ancient Java, the head of the family used shadow plays to teach the younger generation national history and ideals. Throughout the Christian era, churches, schools, and communities have used Christian plays and pageants for the edification of the young; and commercial theaters in Europe have long offered children folk and fairy plays during the Christmas season.

The first theater founded especially for children was established by the Comtesse de Genlis (1745-1830) at St. Etien, France, in 1782. In that year the countess, a brilliant social success in the amusement-mad top circles of France at

he time, was made *gouverneur* of the children of the duke de Chartres; and she thereafter used her talents primarily in planning and operating a beautiful little theater, training her pupils to appear there in plays which she wrote with the object of inculcating moral and social virtue.

But if the Comtesse de Genlis was the first person to take a children's theater into her own hands, she was far from the last. Inga Björnson, for example, founded the first children's theater in Norway, at Oslo, in 1922, and continued thereafter to carry the finances, rehearse the plays, and persuade Norwegian authors to write folk and fairy plays for her theater. She also organized a children's orchestra to provide music, and her child actors enjoyed real training. Before, during, and after World War II, Antigone Mataxas in Athens, Greece, carried the entire burden of a children's theater, writing and rehearsing the plays, and assuming responsibility for the bills. In Prague, Czechoslovakia, Mila Mellinova drew professional actors into her Theater of Youth (established in 1935), an institution which arranged for the production of a series of 324 fairy tales, and in 1946 visited many towns and cities. This group finally secured its own building, in which children playing children's roles appeared with adult professional actors. In Stockholm, Sweden, Elsa Olenius, stimulated by the disorganization of child life which occurred during World War II, established the first children's theater in her country which was able to give performances with its own decorations and costumes. In New York City, the philanthropist August Heckscher, instead of personally carrying such an enterprise, endowed a foundation "for the recreation, education and welfare of children" which included a children's theater. In London, England, private funds launched The Children's Theatre, Ltd., under the management sponsored by John Christie, organ builder and musical amateur whose productions of opera at Glyndbourne, Sussex, achieved international fame. In addition to giving regular performances, the Glyndbourne management carried plays to schools.

Less striking, but even more dynamic a force in developing plays for children, is the work of groups which have been stirred into action by individual enthusiasts. Hull House, for example, the first settlement house in the United States (established in 1889), was only four years old when a 16-year-old lover of plays and children started a children's theater, since when dramatic work with children has become a recognized part of settlement work. In Palo Alto, Calif., Hazel Robertson was so eager to demonstrate the value of plays for children that she began directing them without remuneration. Within five years the community had provided building, equipment, and salary; and Stanford University shortly thereafter began offering a course in children's theater whose students do field work at the community plant. In Evanston, Ill., Winifred Ward in 1915 persuaded Northwestern University, the city schools, and the community to collaborate in organizing a children's theater, which has sent trained workers to universities and communities throughout the United States. In addition, Miss Ward correlated courses in creative dramatics in the schools and university with her

theater, and convinced a large following that all directors of child actors should understand and apply creative techniques. An outstanding example of what can be done by an aroused group is the work and record of the Junior League in the United States. Stimulated by Helena Adamowski, Junior Leagues began producing occasional plays for children at about the turn of the century. As interest grew, a national association provided a professional field staff which held conferences, interested local institutes, encouraged writers by establishing a manuscript library, pioneered in touring (81 leagues gave 1,016 performances for 445,161 children in 1945-1946), and joined in the efforts to stir universities and communities to action.

From the late 1930's on, the growth in the United States of the whole children's theater field has been amazing. Under the stimulus of the American Educational Theatre, more and more high schools have been producing plays for children; more and more universities have instituted courses in creative dramatics, and children's theaters which they use as "laboratory work" for their courses. Often, following the lead of Northwestern University and Leland Stanford University, these theaters are combined with community efforts. The newly formed American National Theatre and Academy, a tax-free organization chartered by the Congress of the United States as a non-profit enterprise, is giving more and more active support to the children's theater movement as part of its policy of supporting the growth of local theaters all over the country. In 1949 a National Children's Theatre Conference was held in New York City, with ANTA's support in finance and publicity. The fact that ANTA's funds come from citizens all over the United States indicates the vitality of the children's theater movement.

In the United States, the interest shown by universities in children's theaters grew steadily. In 1946 and 1947 the American Educational Theatre Association devoted meetings to the children's theater, discussing among other things its possibility as a field of activity and research for graduate students. Community interest has produced children's theaters too numerous to be listed, and the number has grown steadily. The production by high schools of plays for children has also gained momentum. In Norway, children's theaters have sprung up in many towns. In England the British Drama League established training courses in all parts of Britain in 1946, and puppet shows were shown without charge in the parks of many cities. In St. Gall, Switzerland, the Theater of Marionettes used children from the higher grades to pull the strings of the puppets and to speak the lines. In Ascona, Switzerland, a group of authors, painters, and sculptors established a marionette theater. In Prague, home of the previously mentioned Theater of Youth, the Young Pioneers set up a second theater for young people, where children were also cast in children's roles. In France, Academicians have written health propaganda plays for children. In Tuoule Garden, Copenhagen, Denmark, one-act fairy tales and short puppet ballets are produced for children. At Dryhaven, outside Copenhagen, more complete plays are produced.

Professional and government support of

children's theaters varies considerably throughout the world. In the United States, semiprofessional companies have exhibited children's plays on tour from time to time with limited success. Government help in the United States has been confined to granting tax exemption to a few non-profit organizations.

In Europe, government is much more active in this field. The Soviet Union, which founded the first government-supported professional children's theater shortly after the Revolution in 1917, greatly increased the number, scope, and facilities of children's theaters after World War II. Plays in the Soviet Union reach children everywhere; studios for training designers, writers, and actors existed in every district by 1946. In 1938, 5 of Moscow's 30 theaters, and 140 of the 748 theaters in the country, were operated exclusively for children; according to *Soviet News* (Feb. 20, 1946), 1,400 children's and puppet theaters were in operation in the Soviet Union early in 1946. In the Netherlands, Jungd Toneel, a government-operated traveling professional children's theater takes plays from Amsterdam to schools throughout the country. Admission is 50 cents; if a child lacks the amount, the school pays it. In England, the Council of London, and also educational authorities elsewhere, began cooperating in 1946 with the Glyndbourne management in taking plays produced by the Glyndbourne professional company to schools elsewhere; the schools pay a flat sum and the children see the plays during school hours, without charge. The famous Old Vic Theatre in London added a Young Vic in 1947, both of which operate with the support and sponsorship of The Arts Council of Great Britain. In Mexico, also, government is interested in children's theater. The Ministry of Education sponsors a company at the Palacio de Bellas Artes in Mexico City which casts children in children's roles and gives very elaborate and beautiful productions.

In this world-wide welter of activity, disagreements abound, but certain trends are clear. Emphasis on creative dramatics as preparation for both actors and audience increases: belief is growing that younger children should create their own plays in activities carried on for their own good. At about the 6th or 7th grade children are ready to take part in plays in which they are subordinated to the good of the audience; at all ages they should see plays which are beyond their power to produce themselves. Competent leadership is proving that all aspects of production have great educational value for children. Prizes and other show-off motivations are growingly discounted. It is generally agreed that a juvenile cast may profitably act any play within its imaginative grasp; that an adult cast may profitably act for a juvenile audience any play beyond the ability of children in finish and content, provided it is given in the children's own terms; that a mixed juvenile and adult cast is often but not always most desirable. The proportion of plays written by those who understand both children and the theater, as compared with the trivial output of those who condescend to children, understanding neither, is rising. Systematic research in the nature and needs of a juvenile audience, pioneered by the Goodman Theatre of the Art Institute of Chicago and spreading in the United States and Europe, promises to affect the writ-

ing and production of plays for children more and more. Results of this research emphasize the importance of the unbroken story, the picture-book aspect of the stage, the emotional qualities of voice and movement resulting from power and sincerity in acting, methods of controlling over-stimulation, and the value of carrying meanings to children primarily through action rather than primarily through words. The Soviet Union is using its highly developed children's theater in this fashion, largely for social and political training. At The Hague, in the Netherlands, a group of Rudolph Steiner's disciples bases The Anthroposophic Theater on Steiner's theory that, up to adolescence, education should offer children not moral and intellectual concepts, but organism-as-a-whole experience of the consequences of conduct, dramatized through parable and picture. Many writers and producers are seeking skill in giving the growing personalities of the juvenile audience interpretative experience through the excitement, laughter, and beauty of the plays they absorb so eagerly. Psychiatry's emphasis on the fact that the human organism never really forgets any experience is heightening the consciousness of the importance of children's theater, since what every child experiences at a play becomes a conscious or unconscious part of him for the rest of his life.

CHILDRESS, Texas, city and Childress
County seat; 106 miles northwest of Wichita
Falls; on the Fort Worth and Denver City Rail-
road; in a cotton, wheat and livestock region,

once part of the OX Ranch. Childress is a trade center and railroad junction. It has cotton gins, and manufactures cottonseed oil, footwear, and meat and dairy products. Pop. (1950) 7,619.

CHILDS, childz, George William, American publisher: b. Baltimore, Md., May 12, 1829; d. Philadelphia, Pa., Feb. 3, 1894. He was a partner in the firm of Childs and Peterson, which in 1856 published Elisha Kent Kane's remarkably popular *Arctic Explorations*, a popularity due in some part to Childs' skillful use of publicity. The Philadelphia *Public Ledger*, which he bought in 1864 in partnership with A. J. Drexel, was the foundation of his considerable fortune. Childs wrote *Recollections of General Grant* (1885) and *Recollections by George W. Childs* (1890).

CHILDS, Marquis William, American journalist: b. Clinton, Iowa, March 17, 1903. He graduated from the University of Wisconsin in 1923 and in 1926 joined the St. Louis *Post-Dispatch*, with which he was associated until 1944. Childs' popular book *Sweden—the Middle Way* (1936) was the result of visits to Europe in 1930 and 1933. It pointed to Sweden as an example of the middle way between uncontrolled capitalism and extreme socialism, describing the Swedish cooperative movements and the public ownership of various natural resources. Later works include *This is Democracy* (1938); *I Write from Washington* (1942); *The Cabin*, novel (1944); and *The Farmer Takes a Hand* (1952).

CHILE, chī'lě, Spanish chē'lá, republic, South America. A country of great natural beauty, Chile is situated on the continent's southwestern coast between the Andes Mountains and the Pacific Ocean. For many years it was considered one of the three ABC powers, with Argentina and Brazil. The word Chile is thought to be derived either from a Quechua Indian word for snow or the Aymará word *Chilli* meaning "place where the earth ends."

Coat of arms.

Chile is bordered on the east by Argentina and Bolivia, on the north by Peru, on the west by the Pacific Ocean, and on the south by Drake Passage. Its geographical configuration, which has been of prime importance in forming a pattern for the country's history, is that of a long, thin, curving ribbon. The total length of the coast is about 2,653 miles. Its width varies from a maximum of 221 miles to about 50 miles. The Chileans, therefore, are naturally directed toward the sea. The total area is 286,396 square miles.

Santiago (known as Santiago de Chile), the capital, has a population of 1,348,283 (1952). The population of the republic according to the census of 1952 was 5,930,809. The basic monetary

unit is the peso. The metric system is the official standard of weights and measures, but the older Spanish units are also widely used.

Chile's flag was adopted in 1817. The lower half is red and the upper half white except for a blue square enclosing a white star in the uppermost corner nearest the staff (see FLAG). The first line of the national anthem, sometimes called *Dulce Patria*, is *Ha cesado la lucha sangrienta* (*The bloody struggle has ended*).

Detailed discussion of Chile is given under the following headings:

THE LAND AND THE PEOPLE

Geographic Zones.—In addition to the generally lofty Andes, which run along the eastern boundary of Chile, there is the Coastal Range, a parallel ridge along the Pacific coast, of more moderate elevations. Between the two mountain chains, from the Peruvian border to latitude 44° S., lies a longitudinal valley, which in the central section of the country (roughly between Valparaíso and Concepción), where it is called the Central Valley, contains the best agricultural land and the main centers of population. Generally speaking, the northern section of Chile is hot and arid, while the southern portion is cold and wet. As is characteristic of the entire South American Pacific coast, good ports are infrequent.

For convenience of characterization, the republic may be divided into five general zones:

(1) Northern Chile (the "Great" North or Norte Grande), extending from the Peruvian border to the Copiapó River, which reaches the Pacific at about latitude 27° 30' S. in central Atacama Province. Although this region, the Atacama Desert, is without vegetation, except in small areas where irrigation has been established, it is in this region that much of the country's mineral wealth is located, notably the sodium nitrate deposits.

(2) North central Chile (the "little" North or Norte Chico), from the Copiapó to the Aconcagua River, which flows into the ocean 12 miles north of Valparaíso. This zone is less hot and arid. Rain falls several times in the year. Though mining is the chief industry, small areas are also devoted to agriculture.

(3) Central Chile, from the Aconcagua to the Bío-Bío River, which enters the Pacific near Concepción. This zone, the Central Valley, has

a temperate climate and fairly abundant rains. Cattle raising, mining, and the cultivation of cereals, vines, and fruits are the leading industries.

(4) South central Chile, from the Bio-Bio to Puerto Montt. Here rains are more abundant and the climate cooler. The chief products are wheat, cattle, and lumber.

(5) Southern Chile, from Puerto Montt to Cape Horn. This zone is cold and rainy. From latitude 43° 30' S. southward for about 1,150 miles is a district of islands and uplands, rich in forests, fisheries, and lands suitable for stockraising.

On the Strait of Magellan is Punta Arenas, capital of Magallanes Province, the southernmost city of the world. Center of a ranching and lumbering region and situated on an important shipping route, it is a thriving, modern city of 34,440 inhabitants. Except for outlying islands, Magallanes terminates on the southeast in the Chilean half of Tierra del Fuego. The eastern half of Tierra del Fuego, belonging to Argentina, separates Magallanes from the Atlantic, but Chilean control of both sides of the Strait of Magellan provides it for all practical purposes with an outlet on that ocean.

Chile claims the section of the Antarctic lying between longitudes 53° W. and 90° W., parts of which are also claimed by Argentina and Great Britain.

West of the Chilean mainland, at distances ranging from 400 to more than 2,000 miles, are a number of islands under Chile's control. Among these are the following (with their approximate distances from the Chilean coast): Juan Fernández Islands (400 miles), on one of which, Más a Tierra, lived Alexander Selkirk, the prototype of Robinson Crusoe; San Ambrosio Island (600 miles); San Félix Island (600 miles); Sala-y-Gómez Island (2,000 miles); and Easter Island (2,300 miles).

Physiography.—The country is essentially a valley enclosed between two ranges of mountains. On the east are the Andes, diminishing in height to the south, where their line is crossed by various rivers and lakes. On the west, a lower parallel range, the Coastal Range, is interrupted at about 42° south latitude by many fjords. The longitudinal valley, admirably fertile between the Aconcagua and Bio-Bio rivers, begins in the arid desert of the north and ends submerged in the ocean in the south. Known as the Central Valley, this plain extends for about 600 miles.

The Coastal Range is geologically older than the Andes. It is lower and less continuous, with an abrupt slope to the west, while sinking much more gradually to the east. In Tarapacá it rises almost from the sea to heights varying from 1,000 to 7,000 feet. In Atacama it averages 3,000 feet, reaching its highest peak in Cerro Colupo (7,000 feet). Farther south it recedes from the sea and sinks in height until it disappears below Tres Puntas, a mining center in Copiapó. It rises again to some 7,000 feet in the central provinces, notably in the peaks of Roble and Campana, near Valparaíso. South of the river Rapel the range becomes lower and more irregular. Farther south it splits into two parallel low spurs. South of the Bio-Bio River it is known as the Cordillera de Nahuelbuta. Still farther south both the range and the parallel valley plunge into the sea. But its peaks and high plains form the line of islands clinging to the curved shoreline, though only at one point, the

Taitao Peninsula, is it visibly united to the continent.

The Andes chain, with many peaks of over 20,000 feet, contains mountains second in height only to the Himalayas. Southeast of Antofagasta, Lullaillaco rises to about 22,000 feet; east of Valparaíso just over the Chilean border is Aconcagua (about 23,000 feet), the highest peak in the Western Hemisphere; and east of Santiago, on the border, is Tupungato (about 22,000 feet). Farther south, in the region northeast of Puerto Montt, the snow-capped volcanoes Llaima and Villarrica, white, cone-shaped Osorno, with emerald Lake Todos los Santos at its foot, El Tronador ("the thunderer"), named for the avalanches which plunge down its slopes, blue glacial lakes, and virgin forests make the breathtakingly beautiful scenery which has earned for Chile the name "Switzerland of South America."

The smaller hydrographic system of the country is formed by rivers that rise on the western side of the Coastal Range. The rivers of the larger hydrographic system, source of unlimited power for industrial uses, begin high in the Andes, descending to the Pacific coast in a series of cascades and great waterfalls.

The only river north of the Copiapó, generally considered the southern limit of the Atacama Desert, which carries its waters to the ocean for more than a few months in the year is the Loa in Antofagasta Province. In the region just south of this, to latitude 35° S.—and particularly in the Valparaíso-Santiago section—rivers are supplied by rains that fall on their watersheds, and are swollen in the warm months of November to February by the snow melting in the mountains. These annual floods bring alluvial silt down into the agricultural valleys to renew their fertility. South of latitude 35° S., however, the rivers are more often subject to floods during June and July than from November to February, since the melting of mountain snow affects the total volume of water much less in these latitudes. Navigable rivers are comparatively few, and in any event they would be called upon to play a less important role in Chile than are the great inland waterways of Argentina and Brazil, since the ocean itself facilitates communication with, or between, the different parts of this narrow country.

Above the southern limits of the arid zones there are saline depressions in lieu of lakes, although in remote ages, before radical changes in climatic conditions occurred, the lake region embraced these northern districts. Lakes are numerous in the south and are often found at imposing elevations.

Climate.—Being in the Southern Hemisphere, Chile has seasons which are the reverse of those in North America. Since its territory extends from subtropical to Antarctic latitudes and from sea level to the highest peak in the Western Hemisphere, it would naturally have many varieties of climate. The cold Humboldt (or Peruvian) Current, which reaches Chiloe Island and thence flows northward to the equator, has a marked effect on the climate of the coast, making the temperature 6° to 7° F. lower than normal for the latitude. Prevailing winds and high altitudes have the same effect upon the climate of the interior. Cold, stormy winters are found in the far south toward Tierra del Fuego, but extremely low temperatures are rare except in the year-round snow-capped peaks of the Andes.

Throughout the central area the climate is temperate. Here mild, wet winters average a low temperature of about 37°F., seldom dropping below freezing. Hot, dry summer days average 84°F.

Differences in rainfall are greater than those of temperature. The northern desert region may go for years without any rain at all, while rain is abundant in the Central Valley and very heavy in the southern (Patagonia) region.

Natural Resources.—The essential characteristics of Chilean flora were given to it during the long prehistoric ages of complete isolation before the Argentine pampas were lifted out of the waters that covered them. Even now the country is shut in by the Andes on that eastern side, and on the north it is cut off from the rest of the continent by deserts. Formerly its isolation was like that of a Pacific island, and naturally it is distinguished botanically by a large number of indigenous species. Among these are several species of *Francoa* and cactus. The hard espino, a species of acacia from which charcoal is made, is found throughout the Central Valley, as is the Chilean pine or *piñón*, the nut of which is highly valued. Chile's national flower, the copihue (*Lupageria rosea*), a lovely red lily about one and one-half to three inches long, grows everywhere in the same region. South of the Bio-Bio River, where the true forests begin, are found the commercial woods, such as laurels, magnolias, various species of conifers, and a variety of beeches. The potato is said to have come originally from Chile. It is still found wild in Chiloe and the adjacent islands and mainland. The bean and peppers are also indigenous, and corn (maize) and quinoa were grown in the country before the Spanish conquest.

The fauna also differs from that of other South American countries to the extent of excluding jaguars, venomous snakes, monkeys, lizards (save in the northern zones), and river turtles. There are 12 genera and 25 species of rodents. In this order are included the beaverlike coypu and the chinchilla, both valued for their fur. Among Carnivora are the wildcat, puma, and fox. Characteristic ruminants are the guemal deer and the small pudu (the latter peculiar to Chile), and those wild members of the llama family, the vicuña and guanaco. Birds, great and small, are the condor, albatross, pelican, giant fulmar, penguin, rhea (South American ostrich), cormorant, barking bird, turco, tapacolo, gull, swan, duck, parrot, and three species of hummingbirds (one peculiar to Chile).

Fish, comparatively rare in the rivers, abound in the ocean near the coast and in the channels of Magallanes Province, and are taken in great numbers in the northern harbors. Chilean waters are also visited by whales and at least six species of seals.

The country's mineral wealth lies mostly in Chile's northern zone. For the uses of mineral resources, see the section *Economic Development*—*Mining*.

Political Divisions, Chief Cities, and Population.—The official census figures for the population of Chile were 3,753,799 for 1920, 4,287,445 for 1930, 5,023,539 for 1940, and 5,930,809 for 1952.

Both birth and death rates are high. The Chilean birth rate was 39.8 per 1,000 inhabitants in 1930 and averaged about 33 per 1,000 during 1950-1952. The death rate declined from 33

per 1,000 in 1923 to about 15 per 1,000 in 1950-1952. The density of population averages somewhat more than 20 persons to the square mile, but more than three fifths of the inhabitants are concentrated in the central region comprising only one fifth of the total area of the republic. In large parts of the northern desert and semi-desert region the average is only about four persons to the square mile, while in the southern provinces of Aysen and Magallanes it is only about one person to the square mile. The distribution of the population by provinces is shown in the accompanying table. The provinces are listed in order of their position from north to south.

Prov	Square miles	Population (1952)	Inhabitants per square mile
Tarapacá	21,346	102,789	4.8
Antofagasta	47,515	184,779	3.9
Atacama	30,843	80,154	2.9

¹ Antarctic territory claimed by Chile.

While the majority of Chileans are of European (chiefly Spanish and Basque) origin, there is a considerable infusion of Indian (Araucanian) blood, especially in the laboring class. British, Irish, German, and other European nationalities have mixed with the largely Spanish upper and middle classes. Remnants of three aboriginal Indian races remain. In the extreme south live the Fuegians, who are mostly nomads. In the valleys and Andean mountain slopes of south central Chile are nearly 100,000 Araucanians. Inhabiting the northern coast region are the Changos, who perform much of the rough labor in mines and nitrate fields.

Immigration into Chile in recent decades has been relatively small. Immigrants exceeded emigrants by an average of about 4,500 annually during the years 1949-1951. Germans and Spaniards made up the largest proportion of immigrants after 1930.

The chief cities, with population figures from the 1952 census, are: Santiago, the national capital, 1,348,283; Valparaíso, 218,829; Concepción, 119,887; Viña del Mar, 85,281; Antofagasta, 62,272; Talca, 55,059; Talcahuano, 54,782; Chillán, 52,576; Temuco, 51,497; Valdivia, 45,128; Osorno, 40,120; Iquique, 39,576; Punta Arenas, 34,440; Puerto Montt, 28,944; and Curicó, 26,773.

ECONOMIC DEVELOPMENT

Chile's principal economic activities received marked stimulus during the 1930's and 1940's, and

were undergoing continued rapid development in the 1950's. The great emphasis laid upon industrialization, however, has caused some disequilibrium in the economy, aggravated by constant inflation. Mining continues to produce sufficient foreign exchange to cover a substantial part of the imports of raw materials and foodstuffs.

In 1950, according to the Corporación de Fomento de la Producción, industry contributed 23 per cent of the total national income, agriculture about 16 per cent, and mining less than 10 per cent. At the same time the gainfully occupied population included 33.5 per cent in agriculture, 20.6 per cent in industry, 9.3 per cent in trade and finance, 4.8 per cent in transportation and public utilities, 4.6 per cent in public administration, 3.9 per cent in mining, and 23.3 per cent in services.

Agriculture and Livestock.—Land suitable for agricultural and pastoral purposes was estimated at 12.7 million hectares in 1952. (One hectare equals 2.471 acres.) About half this area (6.8 million hectares) is under pasture, and 2.7 million hectares are fallow in natural grasses. The remaining 3.2 million hectares are under cultivation, mostly in cereals (about 80 per cent). It is estimated that about 60 per cent of the Chilean territory is not suitable for agricultural, pastoral, or forestry purposes. The low amount of land suitable for cultivation poses a serious problem for agricultural development. This problem has been aggravated by improper land use, caused mainly by an improper land tenure system—over 90 per cent of the arable land remains in the hands of less than 5,000 proprietors. The remaining 10 per cent is distributed among over 200,000 small farmers.

The principal agricultural region of Chile extends from slightly to the north of Valparaíso to Valdivia in the south central part. This includes the Central Valley, one of the garden spots of the world. The three leading crops are wheat, barley, and oats. Rice, corn, beans, peas, lentils, potatoes, onions, garlic, fruits, and nuts are also produced. The principal fruits are apples, melons, and grapes. These are shipped to the New York market from Valparaíso during the winter months in the United States. Chilean wines are exported not only to all parts of the Western Hemisphere but also to Europe. Nearly 80,000,000 gallons were produced in 1950. A great variety of vegetables is grown and large quantities of beans, peas, lentils, chick-peas, and onions are normally exported. Chile produces enough cotton to supply one third of the requirements of her cotton mills. Other crops are alfalfa, clover, beet and cane sugar, and tobacco.

The livestock industry is an important one. Wool, hides, and skins, and fresh and frozen meats are the chief products. In 1946, 193,832 metric tons of beef and veal, 55,137 of mutton, 25,160 of pork, and 1,320 of goat meat were processed. Wool production runs around 20,000 metric tons annually. About two fifths of the flocks are grazed in the southern province of Magallanes. Cattle raising is largely for the domestic market, although considerable quantities of cattle hides are exported.

Forests.—Chile's main forested area lies in the southern part of the country between latitudes 37° S. and 44° S. The state owns about one half of the forest lands, which cover one fifth of the entire country. The principal trees from which lumber is produced are the roble, laurel, coigue, pine, and eucalyptus. The total fellings of conifer-

ous and broad-leaved woods in 1951 were 2,290,000 cubic meters for industrial purposes and 3,300,000 cubic meters for fuel, including wood for charcoal.

Fisheries.—Some 93,000 metric tons of fish, crustaceans, and mollusks were caught in 1951. The coastal waters abound in over 250 varieties of fish, including haddock and sole. There are also excellent oysters, lobsters, and anchovies. The whaling industry is carried on from Corral, Talcahuano, and Punta Arenas. The catch totaled 33,105 metric tons in 1950.

Mining.—Minerals account for over three fourths of the value of all Chilean exports, and create approximately one half of the foreign exchange available for the purchase of imports. The northern part of Chile depends almost entirely upon mining industries, and the agricultural and industrial sections of central Chile are to a considerable extent employed in producing for the northern mining region. Thus, in addition to some 89,000 workers directly employed in mining in 1950, the economic influence of the industry was felt throughout the republic.

Of the total exports in 1950, copper accounted for 51 per cent by value, and sodium nitrate and its byproduct iodine for more than 22 per cent. Copper was the leading export before the rise of the nitrate industry in the 1880's, and it regained this position in 1932. Chile remained the world's leading producer of copper until 1881, when it was supplanted by the United States; since then it has generally maintained second place. Among the South American countries, Chile is perhaps the richest in mineral resources, ranking first in the production of copper, nitrates, and coal, and high in production of iron ore. The coal output is all consumed in Chile. Practically all the other minerals are exported, chiefly to the United States. They include gold, silver, lead, tungsten, molybdenum, bismuth, manganese, mercury, aluminum, and zinc. Production of the principal minerals in 1913, 1929, 1939, and 1951 is shown in the accompanying table. The figures are for metric tons, except as noted.

	1913	1929	1939	1951
Metals				
Copper, ¹ tons	42,203	320,600	304,494	379,726

³ Figure not available.

In 1951 Chile produced 16 per cent of the total world production of copper. The copper mining industry is controlled largely by United States capital. The copper deposits occur in the Coastal Range and in the lower slopes of the Andes in both northern and central Chile. Over 90 per cent of the total output comes from three large mines: the Chuquicamata, owned by the Chile Copper Company; Potrerillos, owned by the Andes Copper Mining Company; and El Teniente, property of the Braden Copper Company.

The exploitation of the great sodium nitrate deposits in the northern desert played a key role in the development of Chile after their ac-

CHILE

quisition from Bolivia and Peru in the War of the Pacific (1879-1884). Until the development of the synthetic nitrate process, Chile enjoyed a virtual monopoly of this valuable mineral. Exploitation of the deposits began commercially about 1831, but it was not until after 1881 that the industry attained great importance. In 1880 the Chilean government imposed an export tax on the rapidly increasing shipments of nitrate. The tax yielded a total of 7,981,000,000 pesos, or nearly \$1,000,000,000, during the years 1880-1930. This was 43 per cent of the ordinary revenues of the government for that period. The nitrate industry, and the steady, substantial income it brought the government, was responsible in large measure for the temporary emergence of Chile as one of the richest and most powerful countries of South America.

In 1889 Chile supplied almost all the world's nitrate, but by 1913 production of the cheaper synthetic product had reduced Chile's share of the world production to one half, by 1918 to about one third, by 1929 to less than one fourth, by 1938 to about one twelfth, and by 1953 about one twentieth. During the years 1914-1918, nitrate exports averaged 2,528,000 metric tons, valued at \$125,793,000. In 1920 they reached 2,746,000 metric tons, valued at \$144,957,000. During the world economic depression of 1929-1934, exports declined. They were only 244,000 metric tons, valued at \$5,361,000, in 1932. This resulted in the virtual elimination of the government's income from the nitrate export tax and led in 1934 to the establishment of a state monopoly. The Nitrate and Iodine Sales Corporation, controlled but only partially owned by the Chilean government, was established to fix annual production quotas and to determine the share of each of the producing companies. The government receives 25 per cent of the gross profits of the corporation. Nitrate production in 1951 was 1,684,000 metric tons.

The mining of coal on a commercial scale began about 1840. Production has increased to over 2,000,000 metric tons annually as a result of tariff protection and other governmental aids. The deposits lie along the coast from latitude 36° S. to the Strait of Magellan. The principal mines are located at Coronel, Lota, Curanilahue, and Lebu.

Iron ore is Chile's most important industrial metal after copper. It has been produced chiefly by the American-owned Bethlehem Chile Iron Mines Company since 1913. Large-scale production began in 1922. Large deposits of high-grade ore are available close to the seaboard, where ore can be shipped by low-cost water transportation. The deposits are confined to a well-defined belt running along the western third of the provinces of Coquimbo, Atacama, and part of Antofagasta. The internal production and consumption of this mineral has increased with the development of a domestic iron and steel industry since 1951.

The exploitation of Chile's natural sulphur deposits on a large scale date from about the beginning of this century. Average annual production during 1934-1951 was about 23,000 metric tons.

Gold, mined in considerable quantity during the 18th century, experienced a marked increase in production in 1929-1934 during the world economic depression and the accompanying increase in gold prices. Production in 1951 was 5,402 kilograms.

The Chilean mining industry was hard-hit by the depression of 1929-1932. The general index

of mineral production in 1932 was barely one fourth that of 1929. Since 1936-1938, however, it has slowly recovered. Using this last period as a base, the general index of mineral production was 120.8 in 1942, but only 113.4 in 1951. Employment in the mining industry dropped from 91,000 before the world depression to 38,000 in 1932, but increased to 89,000 by 1950.

Industry.—Chile is one of the leading industrial nations of South America. In spite of difficulties caused by the limited local market and the lack of raw materials and sufficient electric power, its industrial development has gained momentum since 1951, when the steel plant at Huachipato, near Concepción, began production under the auspices of the governmental Corporación de Fomento de la Producción. In that year the plant produced some 220,000 metric tons of cast iron, 178,000 tons of steel ingots, and 279,000 tons of laminated products. These figures were surpassed in 1952 (247,558 tons of cast iron, 242,591 tons of steel ingots, and 386,000 tons of laminated products), and it was estimated that the plant would make even greater gains in 1953. This steel production, augmented by older plants at Valdivia and Santiago, favors the expansion of existing industries and the founding of new ones.

Railway cars are manufactured in Chile, and airplanes are assembled at a Curtiss-Wright branch factory. Three plants with an annual capacity of over 100,000 automobile tires operate under United States trade names. The country has three large cement plants, which supply all the domestic demand. In addition, Chile supplies all its own requirements of woolen textiles, pharmaceutical and toilet articles, shoes, paper (except newsprint), explosives, wood products, and tobacco products. It produces a substantial share of the paint, cotton textiles, and industrial chemicals needed. Vegetable oils, beverages, clothing, knit goods, sanitary fixtures, cordage, building products, and printed matter are other important products. Chile leads the world in the production of iodine, a byproduct of the nitrate industry.

Foreign Trade.—As is the case with most Latin American countries, Chilean foreign trade rests upon the exportation of a few products, in this case copper and nitrates, which together account for over 75 per cent of the total value of exports. The remaining 25 per cent is made up chiefly from the exportation of a few agricultural products (beans, peas, lentils, barley, hemp fiber, hides, rice, wines, and fruits), iodine, and iron ore. In exchange for these, Chile obtains industrial and agricultural machinery and equipment, some raw materials for native industries, crude petroleum, gasoline, and consumer goods, mainly foodstuffs, textiles, home appliances, automobiles, rubber articles, and luxury items.

Throughout the 1940's Chile managed to maintain an export balance in foreign trade. To attain this objective, severe import restrictions had to be imposed by the government. Exports in 1950 amounted to \$293.8 million, which represented a 103 per cent increase over the 1938 figure. Imports amounting to \$247.9 million had increased 140 per cent in 1950 as compared with 1938, the year that Chilean trade began to recover from the depression of the 1930's, which hit the country very hard.

The trend of Chilean foreign trade for selected years since 1913 is shown in the accompanying table.

The United States is Chile's main supplier and

	Imports	Exports
	(Values in thousands of U.S. dollars)	
1913	\$120,274	\$142,802
1929	196,858	279,146
1932	26,018	35,353
1938	103,035	141,010
1945	156,122	210,699
1946	196,934	229,983
1947	269,892	280,043
1948	270,400	329,907
1949	304,583	308,337
1950	247,958	293,794

customer, but Argentina, Brazil, and Peru do a sizeable volume of business with Chile. Great Britain, France, Germany, and Italy are Chile's leading European foreign traders.

Currency and Exchange.—After struggling for many years with the problem of a widely fluctuating inconvertible paper currency, the Chilean government in 1925 accepted the recommendations of an American financial mission headed by Professor Edwin Walter Kemmerer of Princeton University and placed the country on the gold standard. Previously the peso, nominally worth \$0.3650 at par, had fluctuated at \$0.18 to \$0.25 on the exchange market. A decree of September 1925 fixed the gold content of the new peso at 0.183057 grams (fine), equivalent to 6 pence sterling or \$0.1217 on the basis of the United States gold dollar and to \$0.2061 on the basis of the currency dollar as revalued in 1934. The gold peso is still used in compiling import and export statistics and in levying tariff duties and certain other taxes.

The value of the paper peso fluctuated widely after Chile abandoned the gold exchange standard in 1931. Its official exchange value is regulated in accordance with the law of April 19, 1932, which authorized the Central Bank to determine international exchange rates. Immediately thereafter the official rate was fixed at 3 pence gold and was maintained at that level until Jan. 2, 1935, when the basis was changed to 1½ pence gold, or \$0.0516 in United States currency; that is, \$1.00 was equal to 19.37 Chilean pesos. As a result of this and other exchange measures adopted by the Central Bank, and of compensation trade agreements concluded with various European countries, four additional exchange markets developed (export draft, curb, free, and gold exchange markets), each quoting exchange at different rates. The true value of the paper peso for foreign commercial purposes was the rate existing in the free, or unofficial, exchange market. Governmental measures taken between 1939 and 1952 established different rates of exchange, according to the purpose for which it was used. In 1950 there were seven exchange rates for the Chilean peso. The average annual values in relation to the United States dollar are shown in the accompanying table.

AVERAGE ANNUAL EXCHANGE RATES OF THE CHILEAN PESO
(Pesos per dollar)

Selling rates	1947	1948	1949	1950
Government	19.37	19.37	19.37	19.37
Preferential	25.10	25.10	25.10	—
Official	31.10	31.10	31.10	31.10
Banking market	—	43.10	43.10	43.10
Provisional commercial	—	—	—	60.10
Special commercial	—	—	—	50.00
Curb or free	47.89	66.66	79.00	91.04

The depreciation of the internal value of the peso has created great disturbances in the Chilean economy. The free rate of exchange dropped from 91.04 pesos to the dollar in 1950 to 220 pesos to the dollar at the end of 1953, when the official rate was 110 pesos per dollar. The purchasing power of the peso in 1950 was one fifth of its purchasing power in 1940.

Finance.—The Central Bank (Banco Central) of Chile is under government control. It was established on Jan. 11, 1926, to serve as the sole note-issuing agency, to regulate general credit, and to supervise banking operations. The bank's credit operations as of Dec. 31, 1952, amounted to 15,513 million pesos,¹ distributed as follows:

(Millions of pesos)	
Loans to the government	5,710
Loans to official institutions	3,950
Loans to the public	2,470
Loans to banks	4,090
Other operations	— 707
Total	15,513

The gold and foreign exchange reserves of the bank were \$67.0 million in December 1952 as compared with \$110.0 million in December 1945. Dollar exchange held in foreign countries by businesses and individuals amounted to \$29.1 million on Dec. 31, 1952.

Government expenditures have run higher than government revenues in Chile, and both have increased tremendously since 1946, as can be seen from the accompanying table based on information released by the Ministry of Finance.

GOVERNMENTAL REVENUES AND EXPENDITURES

	Revenues	Expenditures	Pesos per U.S. dollar ¹
	Millions of pesos		
1940	2,698	2,925	33.90
1946	7,674	9,039	39.50
1947	11,837	12,471	50.93
1948	15,642	14,739	65.55
1949	16,621	16,636	99.08
1950	18,824	22,269	72.50
1951	27,255	29,612	92.60
1952	33,394	43,656	128.50

¹ Free exchange rate, end of years.

Chile's revenue structure is based principally on indirect rather than on direct taxation. In fact, more than 60 per cent of the revenues derived from taxation originate in indirect taxes. Custom duties and import and export taxes are other major sources of revenue. Government borrowing from the Central Bank and from other sources is required to cover government expenditures which cannot be covered by the ordinary revenues. The internal debt on Dec. 31, 1950, amounted to 5,090 million pesos.² The external debt of the same date was as follows:

In pounds sterling	21,735,522
In United States dollars	114,791,000
In Swiss francs	93,297,000

The service of the foreign debt was resumed in 1948; it had been suspended in 1935.

Transportation and Communication.—The highways of Chile in 1951 aggregated 50,267

¹ Free exchange rate, end of 1952, 128.50 pesos per U.S. dollar.

² Free exchange rate, end of 1950, 72.50 pesos per U.S. dollar.

kilometers, 43,523 km. of which were improved types. Automotive vehicles in the same year numbered 78,610, of which 43,390 were automobiles. The Chilean section of the Pan American Highway runs from the Peruvian border in the north, into the Central Valley, and then east across the Andes to Uspallata Pass on the frontier with Argentina. Although the road over the pass is blocked during the winter season, automobiles may nearly always use the railroad tunnel below.

The government-operated airline, Línea Aérea Nacional, links Santiago with Arica in the north and with Puerto Montt and Punta Arenas in the south. International air systems connect Santiago with the chief cities of South and North America and Europe.

Chile had some 6,635 miles of railway lines in 1948, of which about two thirds were state-owned. The state lines connect Pisagua, the northernmost nitrate port, with Puerto Montt in the south. Branch lines extend to the chief ports and the principal towns of the interior. An electric express connects Valparaíso and Santiago. There are four trans-Andean railway routes: Arica to La Paz, Bolivia, opened in 1913; Antofagasta to Uyuni (Bolivia) and Buenos Aires; Antofagasta to Salta (Argentina) and Buenos Aires; and Valparaíso to Mendoza (Argentina) and Buenos Aires. The Andes may also be crossed by a combination route: by rail from Santiago to Osorno in the south, then by lake steamer and automobile to Bariloche, Argentina.

Chile's extremely long coastline makes coastwise steamer transport very important. All ports are served by Chilean vessels. There was a gross registered tonnage of 169,000 in 1950. One Chilean steamship line connects Chilean ports with New York via the Panama Canal and with Europe via the Strait of Magellan.

Other communication facilities include about 15,800 miles of telegraph lines (10,700 miles government-owned); some 5,000 miles of telephone lines serving 137,700 telephones (1952) and connecting all the Chilean cities; radiotelephone and cable services to the countries of Europe and North America; an extensive wireless telegraph system that provides the chief means of communication for the isolated southern provinces; and more than 75 radio broadcasting stations. There are approximately 1,150 post offices handling about 100,000,000 pieces of mail annually.

GOVERNMENT AND EDUCATION

Political Organization.—Chile's constitution was promulgated on Oct. 18, 1925. It provides for a republican form of government; executive, legislative, and judicial branches; separation of church and state; religious freedom; and social welfare as a function of the state.

Under it the president is the chief executive, and is elected by direct popular vote for a term of six years. He may not immediately succeed himself. The president appoints his cabinet, officials of the ministries, diplomatic agents, intendants, governors, magistrates of the higher courts of justice and some inferior courts, and other civil and military employees. The cabinet ministers may attend sessions of the legislature and take part in deliberations, but may not vote.

The chief governmental authority in each province is vested in the intendant as the agent of the president. The intendant is advised by provincial assemblies. The provinces are subdivided

into departments administered by governors, then further subdivided into communes governed by mayors, who, like the governors, are appointed by the president. These mayors are aided by elected aldermen or *regidores*.

The National Congress is composed of two branches, the Chamber of Deputies and the Senate. Deputies are elected by departments, or by groups of adjoining departments within each province, one deputy for each 30,000 inhabitants or fraction of not less than 15,000. The Chamber is renewed every four years. It alone may bring accusations against the president and other officials. Senators are elected in nine provincial groups, five senators to each group, each for a term of eight years. Provision is made to renew the Senate in part every four years. A two-thirds vote of both chambers is necessary to pass bills over the presidential veto.

A Supreme Court at Santiago is provided for, as well as courts of appeal, tribunals of first instance, and lesser courts throughout the republic. Supreme Court justices are appointed by the president from a list submitted by the court. The Chilean civil code, which was prepared by Andrés Bello and went into effect in 1857, is still essentially in use, although modified and amended. A model of scientific legislation, it includes the subjects of persons, property, obligations, contracts, domestic relations, successions, and inheritance. Additional legislation in the fields of commercial, administrative, criminal, and labor law also governs the country.

Chilean citizens 21 years of age or over who can read and write and are registered are entitled to vote in all elections. Women, and foreigners resident in Chile for five years, may vote in municipal elections.

National Defense.—Under the Chilean compulsory military service system, youths are called to the colors at the age of 20, usually for a year and a half. They then serve for 12 years in the active army reserve and for the next 11½ years in the second-line reserves. The army is organized in three army corps and one army division, one cavalry division, and a railway regiment. In 1948 there were 1,900 officers and 18,500 men.

The principal vessels of the Chilean Navy are the battleship *Almirante Latorre* of 28,000 tons displacement, launched in 1913, but refitted and remodernized, and the 10,000-ton cruisers *Capitán Prat* (launched in 1937) and *O'Higgins* (1936), formerly the *Nashville* and *Brooklyn*, purchased by Chile from the United States in 1951. The navy also has destroyers, submarines, and various smaller craft. Naval personnel normally numbers about 13,000. There is a naval academy at Talcahuano near Concepción.

Labor and Social Welfare.—Urban labor in Chile enjoys some of the Western Hemisphere's most advanced legislation relating to low-cost housing, social security, and accident insurance. The groundwork for this legislation was laid during the administration of President Arturo Alessandri in a series of labor laws, which, although not adopted by Congress immediately, formed the basis of other laws passed in 1924 relating to labor contracts, arbitration tribunals, and accidents at work. Additional laws and decrees were aimed at extending social security and retirement benefits to employees of private industry and to persons in the professions. In 1945 all provisions of previous laws and decrees

relating to labor were codified in the official labor code of Chile.

The Chilean labor movement had its beginning in the latter part of the 19th century, but not until 1925 did it gain real strength and importance with the passage of a law authorizing the establishment of labor unions. The largest federation of labor unions, the Confederation of Chilean Workers (*Confederación de Trabajadores de Chile*), was formed in 1936. Its membership is varied and includes miners, teachers, artisans, and factory workers. A total of over 1,800 labor unions were organized between 1925 and 1950.

The principle behind Chilean social security legislation is that such assistance is not charity but a right of citizenship and essential to national progress. The Workers' Compulsory Social Security Fund, established in 1925, includes such benefits as medical attention for the insured and their wives (before and after childbirth), milk for babies, medical care for children up to two years old, old-age and disability benefits, funeral expenses, and dental care. The fund also gives special attention to preventive medicine, especially to tuberculosis, venereal, cardiovascular, and infectious diseases. In addition some 40 other institutions offer benefits to workers.

The government has long been interested in low-cost housing. It established the Council for Workers' Housing in 1906, and in 1949 a new housing agency, the People's Housing Fund, constructed 4,650 dwellings, as compared with 2,000 in 1948. However, all these efforts have only scratched the surface, and the standard of living is still incredibly low and the accident rate high.

Rural labor lags far behind in comparison with the benefits obtained by urban workers. Farmers enjoy no pensions or health insurance. Farm laborers (*inquilinos*) are allowed by the proprietors of large estates to take up as much land as they can till with the aid of their families. They pay no rent, and the produce of the land is their own. However, each laborer must sell his services to the landlord whenever the need arises and at less than prevailing wages. Thus a permanent supply of labor is assured the landlord, but the farm laborer is obliged to work for the landlord at precisely the time his own little plots need attention. This results in apathetic, inefficient service on both big estates and small plots.

Education.—Suitable educational facilities for the middle and upper classes in the cities were developed in the latter half of the 19th century, but it was not until after World War I that the task of educating the rural and urban working classes was taken in hand. In 1920 elementary education was made compulsory for at least six years in the cities and four years in the rural sections. In 1928 the compulsory rule was extended to include all children between 7 and 15. The compulsory attendance law was enforced only partially, as many districts were without educational facilities. Moreover, the population continued to increase at a faster rate than the number of schools; from 1940 to 1950 the total population rose 18 per cent while only 1.2 per cent more schools were established. In 1950, out of 1,266,413 children of school age, 535,237 were enrolled in 3,683 public primary schools. The illiteracy rate for the total population, estimated at 50 per cent in 1920, declined to approximately 26.5 per cent in 1940 and has since continued to fall at a steady rate.

Primary education is free and nonsectarian.

During the 1920's the schools were reorganized in accordance with modern methods. The government brought in a group of well-trained German teachers, who were placed in charge of normal and pedagogical school classes. Psychology courses and new teaching methods were introduced. Another reorganization, placing stress on vocational training, was undertaken beginning in 1939. Chile has given special attention to the training of primary teachers. Public and private kindergartens are available for children from four to six. Secondary schools are both public and private; the government *liceos* give six-year courses. There are also numerous special vocational schools.

There are five institutions of higher learning, headed by the University of Chile, which must approve candidates for degrees of the other universities. The others are the University of Concepción, Federico Santa María Technical University at Valparaíso, and the Catholic universities at Santiago and Valparaíso. In addition, the Institute of Bacteriology provides training for public health physicians and bacteriologists, and there are three schools of social service. Educational statistics for 1948, for both public and private schools, showed 745,999 pupils in 5,947 primary schools; 74,721 in 296 secondary schools; 3,819 students in 13 normal schools; 65,104 in 203 special schools; and 9,061 in the universities.

HISTORY

The dominion of the Incas of Peru included the northern and central portions of Chile—probably no farther south than the Maule River. In 1535 the Spanish conquerors of the Inca Empire sent their first expedition southward along the Pacific coast; but the task of adding this territory to the Spanish possessions in Peru and Upper Peru (Bolivia) was not undertaken in earnest until 1541, nor was it brought to a successful conclusion without desperate fighting in the second half of the 16th century. The conqueror Pedro de Valdivia, founder of Santiago in 1541, suffered defeat and death in 1553 at the hands of Lautaro, the young Indian leader—not of the famous Caupolicán as many writers have asserted. The conquest was resumed by García Hurtado de Mendoza in 1557–1561, and Spaniards reached the Strait of Magellan; but the Araucanians offered a stubborn resistance, and even as late as the 19th century they made good their prior claim to a large part of the country below the Bío-Bío.

Having been conquered from Peru, Chile became part of the Peruvian viceroyalty. It was administered by governors, who presided over the *audiencia* established in Santiago in 1609. In 1778, however, when the Spanish colonial system was reorganized by Charles III, Chile became a captaincy general, and received virtual autonomy of Peru.

Independence.—The first national government was proclaimed on Sept. 18, 1810, to rule the country in the form of a junta during the captivity of the king of Spain, whom the French held prisoner. The first national congress of Chile met on July 4, 1811. Among the leaders present was Bernardo O'Higgins, son of an Irish-born former viceroy of Peru. O'Higgins had been educated in England, and while there became acquainted with Francisco Miranda and other forerunners of Latin American independence. He carried home his dream of sovereignty for Chile, a dream he never relinquished despite setbacks.

Grace Line

The first ruler of independent Chile was José Miguel Carrera, who ruled the country as dictator from 1811 to 1813, when he was replaced by O'Higgins. Assisted by the rivalry between the two leaders, royalist armies from Peru reconquered the country after a bitter struggle. Following O'Higgins' defeat at Rancagua near Santiago on Oct. 1-2, 1814, the patriot army of some 3,000 men crossed the Andes to Mendoza.

Final victory was won in 1817-1818 with the help of Argentine troops under Gen. José de San Martín. Following the victory of Chacabuco (Feb. 12, 1817), which delivered Santiago to San Martín, the latter was offered the office of supreme director of Chile, but declined it in favor of O'Higgins. The independence of the country was proclaimed on Feb. 12, 1818, and made a reality with the decisive victory of Maipú (April 5, 1818) in defense of Santiago, although Spain did not formally recognize Chile as an independent power until the conclusion of a treaty in 1844.

O'Higgins' first task was to restore law and order. He built a navy, improved cities, promoted trade and agriculture, and opened public schools and libraries. In spite of the prosperity that these reforms brought, opposition by the landed aristocracy to some of O'Higgins' policies caused him to call a constituent assembly in 1822 for the purpose of drafting a constitution to settle the form of government. This constitution did not come into force, however, since continuing unrest forced O'Higgins to resign on Feb. 28, 1823. The various factions could not be reconciled, and, following the supreme directorship (1823-1826) of Ramón Freire, their conflicts resulted in numerous changes of government and constitutions, finally culminating in civil war (1829-1830) between Conservatives and Liberals, in which the former were victorious. The Constitution of 1833 established a semipopular form of centralized republican government which endured until 1925. Diego Portales (1793-1837), who exercised dictatorial control while holding various offices in the cabinet, was the dominant figure of the time.

The period of Conservative supremacy lasted through the administrations of presidents Joaquín Prieto (1831-1841), Manuel Bulnes (1841-1851), and Manuel Montt (1851-1861), and may be said to end with the election in 1861 of José Joaquín Pérez, candidate of the moderate Liberals and Conservatives, but acceptable to the opposition. The principal event in foreign affairs during this period was the war (1836-1839) in which the Chileans overthrew the confederation of Peru and Bolivia under Andrés Santa Cruz. In 1864 hostilities broke out between Peru and Spain, and Chile declared war on the latter in the next year. Valparaíso was bombarded by a Spanish Fleet on March 31, 1866, but there were no engagements of major importance.

Liberal Era.—President Pérez was followed by Federico Errázuriz Zañartu (1871-1876), Aníbal Pinto (1876-1881), under whom began the War of the Pacific, and Domingo Santa María (1881-1886), under whom the war was concluded.

War of the Pacific.—For many years the respective rights of Bolivia and Chile in the nitrate region bordering the Pacific Ocean remained undecided; but in 1874 an agreement was entered into between the two countries, which apparently disposed of the question at issue, fixing the boundary at latitude 24° S. Since the exploitation of these lands by Chileans was increasing, Bolivia

reopened the dispute in 1878 by imposing an export tax on the nitrate obtained in Bolivian territory. A Chilean company at Antofagasta refused to pay the tax, alleging that it violated the treaty of 1874. The Bolivian government's reply was an order for the sale at auction of the property of the offending company. Thereupon the Chilean government sent a man-of-war and soldiers to seize the port of Antofagasta (Feb. 14, 1879). Bolivia declared war on March 1, but it soon became apparent that Chile would have to reckon with Peru also, since that country had signed a secret defensive treaty with Bolivia in 1873. Chile declared war against the allies on April 5, 1879. The presidents of Peru and Bolivia assembled their forces at Tacna, and its neighboring port of Arica, and the defense of Iquique, which was being blockaded by Chilean warships, was entrusted to a sufficient force.

The initial success in the all-important struggle for control of the sea fell to the allies. Two wooden warships blockading Iquique, the corvette *Esmeralda* and the gunboat *Covadonga*, were attacked by two Peruvian ironclads, the frigate *Independencia* and the turret ship *Huáscar*, on May 21, 1879. The *Huáscar* sank the *Esmeralda*, but the *Independencia* ran aground and was destroyed, the *Covadonga* escaping southward. Five months later, on October 8, the *Huáscar* fell in with the two powerful ironclads *Cochrane* and *Blanco Encalada* of the Chilean Navy off Point Angamos near Mejillones. A fight of great severity ensued, ending with the surrender of the Peruvian vessel, which was repaired and added to the Chilean Navy. For all practical purposes, the Peruvian Navy had now ceased to exist, and the resulting ability of the Chileans to move their troops by sea at will proved decisive.

A Chilean army had assembled at Antofagasta, whence part was transported north of Iquique to Pisagua, which was captured on Nov. 2, 1879. The allies, advancing with reinforcements, were defeated in the Battle of San Francisco (or Dolores) November 19, but before the close of the month they won a hard-fought battle against the Chileans at Tarapacá on the 27th. Nevertheless, the allies abandoned the region to the Chileans, and the next Chilean attack was delivered on the Peruvian coast above Arica, a Chilean army landing at Ilo on Feb. 25, 1880. It advanced inland in March, capturing Moquegua and crushing the allied army at Tacna on May 26. This ended Bolivian participation in the war. The port of Arica was attacked by Chilean land and sea forces, and fell on June 7, after resisting desperately.

In order to bring the war to a rapid conclusion, the Peruvian coast was then laid waste by the Chileans. Mollendo was destroyed, Callao and other ports were blockaded, and in November and December 1880 Chilean forces were landed south of Lima at Pisco and near Lurín, whence they advanced on the Peruvian capital. Following two sharp engagements near Lima, the city fell to the Chileans on Jan. 17, 1881, thus in effect ending the war, although the Peruvians kept up a guerrilla resistance for another two years.

As the fruit of her victory, Chile occupied the entire Bolivian seacoast, thus cutting that country off from the Pacific, as well as Peruvian territory north to and including, conditionally, the districts of Arica and Tacna. A truce was concluded between Bolivia and Chile by the Treaty of Valparaíso (1884), although the Bolivians were utterly averse to any permanent arrangement

which did not give them access to the sea. Renewal of negotiations for a definite treaty, which would include the concession of a seaport to Bolivia, was repeatedly urged by that country, but without success. Thus the war was not formally ended until Oct. 20, 1904, when Bolivia recognized Chilean possession of her former seacoast.

Peru, by the terms of the Treaty of Ancón (1883), surrendered unconditionally to Chile the valuable nitrate province of Tarapacá, but with respect to the Tacna-Arica region an unusual agreement was made. It was agreed that Tacna-Arica should be governed by Chile for a period of 10 years, and that at the end of that period the inhabitants of the region would decide by plebiscite whether the region should revert to Peru or should continue being administered by Chile. The country losing the plebiscite was to receive 10,000,000 Chilean silver pesos from the winner as compensation. The plebiscite did not take place and the plan was abandoned in 1926. However, in 1929 an agreement was reached whereby Chile kept Arica and gave up Tacna, besides agreeing to pay Peru \$6,000,000 gold.

Liberal Reforms.—During the decade preceding the War of the Pacific, liberal elements succeeded in winning control of the government. Against the bitter opposition of the large landowners, the Roman Catholic Church, and other conservative forces, the liberals gradually carried out a series of political, economic, and social reforms that radically modified, although they did not entirely eliminate, the oligarchic nature of the government. Religious freedom was established. The power of the president was restricted and his re-election barred by constitutional amendment. The special privileges of the church were restricted, although it was not until 1925 that the campaign for separation of church and state succeeded. Education was extended and public works built on an unprecedented scale, especially after the conquest of the Bolivian and Peruvian nitrate fields brought the Chilean state large additional revenue (see section on *Economic Development—Mining*). Income and property requirements for voting were abolished, greater powers of local self-government were granted, and the parliamentary form of government was strengthened. Moreover, returning veterans of the War of the Pacific crushed the independence of the warlike Araucanians, who had remained masters of the territory south of the Bio-Bio River, and had risen against the whites in 1880. They were placed under a protectorate in 1883.

Congressional Revolt.—Under the outstanding liberal president José Manuel Balmaceda (1886-1891), further reforms were introduced and the country enjoyed exceptional prosperity. However, his dictatorial tendencies, particularly his refusal to appoint a cabinet satisfactory to Congress, precipitated a congressional revolt in 1891. The navy and all conservative elements rallied behind Congress in the ensuing civil war. Balmaceda's forces were defeated, and he committed suicide (Sept. 19, 1891). The leader of the congressionalists, Jorge Montt, then became president (1891-1896), and was succeeded by Federico Errázuriz Echaurren (1896-1901), Germán Riesco (1901-1906), Pedro Montt (1906-1910), Ramón Barros Luco (1910-1915), and Juan Luis Sanfuentes (1915-1920).

Without replacing the constitution, the revolt against Balmaceda inaugurated a new political

system. The presidents of Chile thereafter generally accepted the wishes of the majority group in Congress, but due to the development of numerous parties and the resulting partisan factionalism and political maneuvering, the results were disappointing. There were innumerable cabinet changes and not infrequent political crises when opposing blocs and the president became deadlocked over some major or minor political issue. As a result of this situation, social and economic progress was retarded and disillusionment with the parliamentary system grew. Efforts to improve the economic and social status of the laboring masses were insufficient to prevent the development of a radical, class-conscious labor movement that was strongly influenced by Marxism. This movement for the elimination of class inequalities and the collectivization of production and distribution gained rapid headway during and after World War I.

Meanwhile Chile passed safely through a series of international crises that repeatedly threatened to precipitate war. The first of these disputes was the *Baltimore* affair. The sympathy shown by the United States minister, Patrick Egan, for President Balmaceda's cause during the civil war aroused resentment against the United States among the partisans of Congress. This resentment flared out in a street fight in Valparaíso on Oct. 16, 1891, between a Chilean mob and a band of sailors on shore leave from the United States cruiser *Baltimore*. Two sailors were killed and several wounded. The Chilean government refused to acknowledge responsibility for the affair until an ultimatum from Washington forced it to apologize and to pay an indemnity of \$75,000.

Soon afterward the possibility of war with Argentina developed over a boundary dispute. This was finally settled peacefully, however, by two separate arbitral awards. The first, covering the Puna de Atacama in the north, was issued in April 1899 by a tribunal headed by the United States minister to Buenos Aires, William Inso Buchanan. The second and more difficult award, along the Andean border, was made in 1902 by King Edward VII of Great Britain after both countries had prepared feverishly for an armed struggle. This settlement is commemorated by the giant *Christ of the Andes* statue, cast from melted cannon and erected at the crest of the Andes over the trans-Andean railway tunnel in 1904. Since then Argentine-Chilean relations have been increasingly friendly, despite their economic rivalries in Bolivia and Patagonia and controversies over part of Antarctica and three small islands in Beagle Channel. Chile's relations with Peru became cordial after the Tacna-Arica settlement of 1929. But landlocked Bolivia still deeply resents the seizure of her Pacific littoral.

After World War I.—Chile remained neutral during the war. A temporary stimulation in the demand for nitrate brought a sharp upturn in the country's prosperity. The end of the war, however, was followed by a period of economic difficulty. Growing pressure for social and political reform, reflected in deep unrest among the laboring and middle classes, resulted in the election of the Liberal Alliance's presidential candidate, Arturo Alessandri, in a very close contest in 1920. The country was on the verge of civil war until his election was validated by a special "tribunal of honor." The first person of the lower classes to occupy the Chilean presidency, Alessandri submitted a far-reaching reform program to Congress.

For several years most of these bills were held up by factionalism in the government-controlled Chamber of Deputies and by the conservative majority in the Senate. Even after the Liberal Alliance gained control of both houses in June 1924, Congress was unable to act. Growing impatient with this situation, a junta of army and navy officers led by Gen. Luis Altamirano seized control of the government by a coup d'état on Sept. 5, 1924. Congress was forced to pass a score of the reform bills in a few minutes and was later dissolved.

Alessandri resigned on September 8 and left for Europe on a leave of absence. Altamirano's junta undertook to rule by decree, but was soon accused of betraying the reform cause. On Jan. 23, 1925, a group of younger military officers led by Carlos Ibáñez del Campo overthrew Altamirano and joined with all political parties in asking Alessandri to return. Alessandri reassumed office from March 21 to Oct. 1, 1925. During this period a new constitution was drawn up, replacing the system of parliamentary rule with that of a strong executive. It was approved by a national plebiscite and promulgated on Oct. 18, 1925. The presidential election held on October 24 was won by Emiliano Figueroa. His administration encountered mounting difficulties, and on May 4, 1927, he was forced to resign in favor of his ambitious minister of interior, Gen. Carlos Ibáñez del Campo.

Under this, Ibáñez's first administration, Chile returned temporarily to the postcolonial system of autocratic rule by forceful dictator-presidents. While ruthlessly curbing all opposition, Ibáñez carried out broad reforms, particularly in education and sanitation, which mark a milestone in Chilean history. He purged the government, temporarily, of corruption, reorganized the administrative, judicial, and fiscal systems, and with the aid of large loans from the United States and increased government revenues from the revived nitrate industry inaugurated an ambitious program of public works.

Beginning in 1929 the Ibáñez regime ran afoul of the world economic depression, which struck Chile with exceptional severity. By 1932 Chilean foreign trade had fallen to one sixth of its 1929 value, while government revenues were less than one third of their former total. It proved impossible to sustain the dictatorship under these conditions. In July 1931 a strike against the regime was begun by university students and it quickly spread to include the laboring and professional classes. Ibáñez fled to Argentina (July 26).

From then until the end of 1932 Chile experienced a bewildering succession of governmental overturns, produced for the most part by military coups. Ex-President Alessandri, candidate of the radical elements, was defeated for the presidency on Oct. 4, 1931, by Juan Esteban Montero, but the latter was overthrown on June 4, 1932, by another coup d'état; and more shortlived provisional governments followed until another election was held on Oct. 30, 1932. This time Alessandri ran as the moderate Socialist candidate against the radical Socialist leader Col. Marmaduke Grove, and was elected. With the support of the landed aristocracy, the bulk of the army, and a private antiradical militia, he served out the full six-year term ending Dec. 24, 1938. Holding diverse and troublesome opposition groups in check by occasional arrests, deportations, and bans of public

meetings, he made substantial headway in overcoming the economic depression through a series of conservative measures formulated for the most part by his influential minister of finance, Gustavo Ross.

Ross, a member of the aristocracy, became the candidate of a bloc of conservative parties in the presidential election of Oct. 25, 1938, but was defeated in a close vote by Pedro Aguirre Cerda, candidate of the leftist Popular Front. Again, as in 1920, the conservative block challenged the validity of the election, and the nation hung on the verge of civil war until army and police chiefs forced Ross to concede his defeat and leave the country. Aguirre Cerda, a wealthy landowner and lawyer of liberal views, pledged his government to provide the poverty-ridden and demoralized Chilean masses with "food, culture, clothing, and housing." He ousted officials sympathetic to the old regime from all departments of the government, army, navy, and police. Immediate steps were taken to introduce an eight-hour working day for public employees and to lower the prices of staple foodstuffs. A program aiming at increased agricultural and industrial production and reduced living costs was announced. It called for the construction of hydroelectric plants to furnish cheap current for new industries, and of new highways, schools, and workers' homes. Farm laborers were to be settled on unused lands and education reorganized on a more popular and vocational basis.

While legislation to carry this program into effect was before Congress, the most disastrous earthquake in the republic's history wrecked six of the richest agricultural provinces of central Chile on the night of Jan. 24, 1939. About 50,000 people were killed, 700,000 left homeless, and property damage estimated at over \$30,000,000 was inflicted. This serious setback to the government's economic program was followed in September by the outbreak of World War II, which curtailed Chile's export markets and raised the prices of imported articles. In 1940 severe storms in the nitrate region of the north and in the Valparaíso district caused further damage. Meanwhile the government was harassed by sporadic conspiracies and minor revolts by opposition groups, by the growing political activities of German Nazi and Spanish Fascist organizations, and by serious dissensions among the Popular Front parties and leaders. Nevertheless, it pushed ahead with its program of economic reform while carrying out an ambitious plan for the relief and reconstruction of the earthquake-devastated regions. Two fiscal corporations to finance new production and reconstruction, respectively, were established under a law promulgated on April 28, 1939. These were the Corporación de Fomento de la Producción (Corporation for the Development of Production) and the Corporación de Reconstrucción y Auxilio (Reconstruction and Relief Corporation). Funds for both purposes were obtained by higher taxes on the wealthy, bank loans, and private and governmental credits obtained in the United States. President Aguirre had hardly begun his work of reconstructing the country when he died on Nov. 25, 1941.

Aguirre Cerda was succeeded by Juan Antonio Ríos, who was elected by a considerable majority of votes on Feb. 1, 1942, with the support of the Popular Front, which was disbanded soon after. Ríos defeated ex-President Carlos Ibáñez del Campo, who was supported by Conservatives,

which did not give them access to the sea. Renewal of negotiations for a definite treaty, which would include the concession of a seaport to Bolivia, was repeatedly urged by that country, but without success. Thus the war was not formally ended until Oct. 20, 1904, when Bolivia recognized Chilean possession of her former seacoast.

Peru, by the terms of the Treaty of Ancón (1883), surrendered unconditionally to Chile the valuable nitrate province of Tarapacá, but with respect to the Tacna-Arica region an unusual agreement was made. It was agreed that Tacna-Arica should be governed by Chile for a period of 10 years, and that at the end of that period the inhabitants of the region would decide by plebiscite whether the region should revert to Peru or should continue being administered by Chile. The country losing the plebiscite was to receive 10,000,000 Chilean silver pesos from the winner as compensation. The plebiscite did not take place and the plan was abandoned in 1926. However, in 1929 an agreement was reached whereby Chile kept Arica and gave up Tacna, besides agreeing to pay Peru \$6,000,000 gold.

Liberal Reforms.—During the decade preceding the War of the Pacific, liberal elements succeeded in winning control of the government. Against the bitter opposition of the large landowners, the Roman Catholic Church, and other conservative forces, the liberals gradually carried out a series of political, economic, and social reforms that radically modified, although they did not entirely eliminate, the oligarchic nature of the government. Religious freedom was established. The power of the president was restricted and his re-election barred by constitutional amendment. The special privileges of the church were restricted, although it was not until 1925 that the campaign for separation of church and state succeeded. Education was extended and public works built on an unprecedented scale, especially after the conquest of the Bolivian and Peruvian nitrate fields brought the Chilean state large additional revenue (see section on *Economic Development—Mining*). Income and property requirements for voting were abolished, greater powers of local self-government were granted, and the parliamentary form of government was strengthened. Moreover, returning veterans of the War of the Pacific crushed the independence of the warlike Araucanians, who had remained masters of the territory south of the Bío-Bío River, and had risen against the whites in 1880. They were placed under a protectorate in 1883.

Congressional Revolt.—Under the outstanding liberal president José Manuel Balmaceda (1886–1891), further reforms were introduced and the country enjoyed exceptional prosperity. However, his dictatorial tendencies, particularly his refusal to appoint a cabinet satisfactory to Congress, precipitated a congressional revolt in 1891. The navy and all conservative elements rallied behind Congress in the ensuing civil war. Balmaceda's forces were defeated, and he committed suicide (Sept. 19, 1891). The leader of the congressionalists, Jorge Montt, then became president (1891–1896), and was succeeded by Federico Errázuriz Echaurren (1896–1901), Germán Riesco (1901–1906), Pedro Montt (1906–1910), Ramón Barros Luco (1910–1915), and Juan Luis Sanfuentes (1915–1920).

Without replacing the constitution, the revolt against Balmaceda inaugurated a new political

system. The presidents of Chile thereafter generally accepted the wishes of the majority group in Congress, but due to the development of numerous parties and the resulting partisan factionalism and political maneuvering, the results were disappointing. There were innumerable cabinet changes and not infrequent political crises when opposing blocs and the president became deadlocked over some major or minor political issue. As a result of this situation, social and economic progress was retarded and disillusionment with the parliamentary system grew. Efforts to improve the economic and social status of the laboring masses were insufficient to prevent the development of a radical, class-conscious labor movement that was strongly influenced by Marxism. This movement for the elimination of class inequalities and the collectivization of production and distribution gained rapid headway during and after World War I.

Meanwhile Chile passed safely through a series of international crises that repeatedly threatened to precipitate war. The first of these disputes was the *Baltimore* affair. The sympathy shown by the United States minister, Patrick Egan, for President Balmaceda's cause during the civil war aroused resentment against the United States among the partisans of Congress. This resentment flared out in a street fight in Valparaíso on Oct. 16, 1891, between a Chilean mob and a band of sailors on shore leave from the United States cruiser *Baltimore*. Two sailors were killed and several wounded. The Chilean government refused to acknowledge responsibility for the affair until an ultimatum from Washington forced it to apologize and to pay an indemnity of \$75,000.

Soon afterward the possibility of war with Argentina developed over a boundary dispute. This was finally settled peacefully, however, by two separate arbitral awards. The first, covering the Puna de Atacama in the north, was issued in April 1899 by a tribunal headed by the United States minister to Buenos Aires, William Insko Buchanan. The second and more difficult award, along the Andean border, was made in 1902 by King Edward VII of Great Britain after both countries had prepared feverishly for an armed struggle. This settlement is commemorated by the giant *Christ of the Andes* statue, cast from melted cannon and erected at the crest of the Andes over the trans-Andean railway tunnel in 1904. Since then Argentine-Chilean relations have been increasingly friendly, despite their economic rivalries in Bolivia and Patagonia and controversies over part of Antarctica and three small islands in Beagle Channel. Chile's relations with Peru became cordial after the Tacna-Arica settlement of 1929. But landlocked Bolivia still deeply resents the seizure of her Pacific littoral.

After World War I.—Chile remained neutral during the war. A temporary stimulation in the demand for nitrate brought a sharp upturn in the country's prosperity. The end of the war, however, was followed by a period of economic difficulty. Growing pressure for social and political reform, reflected in deep unrest among the laboring and middle classes, resulted in the election of the Liberal Alliance's presidential candidate, Arturo Alessandri, in a very close contest in 1920. The country was on the verge of civil war until his election was validated by a special "tribunal of honor." The first person of the lower classes to occupy the Chilean presidency, Alessandri submitted a far-reaching reform program to Congress.

For several years most of these bills were held up by factionalism in the government-controlled Chamber of Deputies and by the conservative majority in the Senate. Even after the Liberal Alliance gained control of both houses in June 1924, Congress was unable to act. Growing impatient with this situation, a junta of army and navy officers led by Gen. Luis Altamirano seized control of the government by a coup d'état on Sept. 5, 1924. Congress was forced to pass a score of the reform bills in a few minutes and was later dissolved.

Alessandri resigned on September 8 and left for Europe on a leave of absence. Altamirano's junta undertook to rule by decree, but was soon accused of betraying the reform cause. On Jan. 23, 1925, a group of younger military officers led by Carlos Ibáñez del Campo overthrew Altamirano and joined with all political parties in asking Alessandri to return. Alessandri reassumed office from March 21 to Oct. 1, 1925. During this period a new constitution was drawn up, replacing the system of parliamentary rule with that of a strong executive. It was approved by a national plebiscite and promulgated on Oct. 18, 1925. The presidential election held on October 24 was won by Emiliano Figueroa. His administration encountered mounting difficulties, and on May 4, 1927, he was forced to resign in favor of his ambitious minister of interior, Gen. Carlos Ibáñez del Campo.

Under this, Ibáñez's first administration, Chile returned temporarily to the postcolonial system of autocratic rule by forceful dictator-presidents. While ruthlessly curbing all opposition, Ibáñez carried out broad reforms, particularly in education and sanitation, which mark a milestone in Chilean history. He purged the government, temporarily, of corruption, reorganized the administrative, judicial, and fiscal systems, and with the aid of large loans from the United States and increased government revenues from the revived nitrate industry inaugurated an ambitious program of public works.

Beginning in 1929 the Ibáñez regime ran afoul of the world economic depression, which struck Chile with exceptional severity. By 1932 Chilean foreign trade had fallen to one sixth of its 1929 value, while government revenues were less than one third of their former total. It proved impossible to sustain the dictatorship under these conditions. In July 1931 a strike against the regime was begun by university students and it quickly spread to include the laboring and professional classes. Ibáñez fled to Argentina (July 26).

From then until the end of 1932 Chile experienced a bewildering succession of governmental overturns, produced for the most part by military coups. Ex-President Alessandri, candidate of the radical elements, was defeated for the presidency on Oct. 4, 1931, by Juan Esteban Montero, but the latter was overthrown on June 4, 1932, by another coup d'état; and more shortlived provisional governments followed until another election was held on Oct. 30, 1932. This time Alessandri ran as the moderate Socialist candidate against the radical Socialist leader Col. Marmaduke Grove, and was elected. With the support of the landed aristocracy, the bulk of the army, and a private antiradical militia, he served out the full six-year term ending Dec. 24, 1938. Holding diverse and troublesome opposition groups in check by occasional arrests, deportations, and bans of public

meetings, he made substantial headway in overcoming the economic depression through a series of conservative measures formulated for the most part by his influential minister of finance, Gustavo Ross.

Ross, a member of the aristocracy, became the candidate of a bloc of conservative parties in the presidential election of Oct. 25, 1938, but was defeated in a close vote by Pedro Aguirre Cerda, candidate of the leftist Popular Front. Again, as in 1920, the conservative block challenged the validity of the election, and the nation hung on the verge of civil war until army and police chiefs forced Ross to concede his defeat and leave the country. Aguirre Cerda, a wealthy landowner and lawyer of liberal views, pledged his government to provide the poverty-ridden and demoralized Chilean masses with "food, culture, clothing, and housing." He ousted officials sympathetic to the old regime from all departments of the government, army, navy, and police. Immediate steps were taken to introduce an eight-hour working day for public employees and to lower the prices of staple foodstuffs. A program aiming at increased agricultural and industrial production and reduced living costs was announced. It called for the construction of hydroelectric plants to furnish cheap current for new industries, and of new highways, schools, and workers' homes. Farm laborers were to be settled on unused lands and education reorganized on a more popular and vocational basis.

While legislation to carry this program into effect was before Congress, the most disastrous earthquake in the republic's history wrecked six of the richest agricultural provinces of central Chile on the night of Jan. 24, 1939. About 50,000 people were killed, 700,000 left homeless, and property damage estimated at over \$30,000,000 was inflicted. This serious setback to the government's economic program was followed in September by the outbreak of World War II, which curtailed Chile's export markets and raised the prices of imported articles. In 1940 severe storms in the nitrate region of the north and in the Valparaíso district caused further damage. Meanwhile the government was harassed by sporadic conspiracies and minor revolts by opposition groups, by the growing political activities of German Nazi and Spanish Fascist organizations, and by serious dissensions among the Popular Front parties and leaders. Nevertheless, it pushed ahead with its program of economic reform while carrying out an ambitious plan for the relief and reconstruction of the earthquake-devastated regions. Two fiscal corporations to finance new production and reconstruction, respectively, were established under a law promulgated on April 28, 1939. These were the Corporación de Fomento de la Producción (Corporation for the Development of Production) and the Corporación de Reconstrucción y Auxilio (Reconstruction and Relief Corporation). Funds for both purposes were obtained by higher taxes on the wealthy, bank loans, and private and governmental credits obtained in the United States. President Aguirre had hardly begun his work of reconstructing the country when he died on Nov. 25, 1941.

Aguirre Cerda was succeeded by Juan Antonio Ríos, who was elected by a considerable majority of votes on Feb. 1, 1942, with the support of the Popular Front, which was disbanded soon after. Ríos defeated ex-President Carlos Ibáñez del Campo, who was supported by Conservatives,

Liberals, Democrats, and independents. President Ríos made a strenuous effort to carry out the work begun by his predecessor, and planned the large steel mill at Huachipato, near Concepción, an important mining center. But Ríos did not live to see the fulfillment of his plans either; he died on June 27, 1946, before completing his term of office. During the Ríos administration Chile aligned herself definitely on the side of the democracies in their fight against the totalitarian Axis powers, severing diplomatic relations with the Axis in 1943 and declaring war on Japan in 1945.

The election of Ríos' successor on Sept. 4, 1946, was a lively contest. A coalition of Radicals, Communists, and Democrats presented Gabriel González Videla as their candidate, who defeated Bernardo Ibáñez, candidate of the Socialists, Eduardo Cruz Coke, candidate of the Conservatives and Falangists, and Fernando Alessandri, candidate of the Liberals, Agrarian Party, and various independent groups. The efforts of the González administration were directed toward trying to put the Chilean economy on its feet in the postwar years, stimulating industry, and raising the standard of living. The industrial development program initiated by González included these latter objectives, as well as a better utilization of the country's natural resources, but political turmoil during his administration did not permit the accomplishment of all that was desired. Shortly after he took office, González broke with the Communist Party (declared illegal in 1948), with whose help he had won the election, and some of whose members held posts in his cabinet. Next he governed with the support of the Radicals, then with the independents, then with various opposition parties, and finally with the aid of some nonpolitical friends. All these "experiments" created widespread discontent, contributing little to alleviating the soaring cost of living. Thus on Sept. 4, 1952, Gen. Carlos Ibáñez del Campo was again elected president, to succeed González Videla. He was elected principally with the support of independents, Falangists, the Agrarian-Labor Party (a Fascist group), and some Socialists. Ibáñez defeated Pedro Enrique Alfonso, Radical candidate supported by the administration and the Conservative Christian Socialists, Arturo Matte Larraín, candidate of the Liberals and Traditional Conservatives, and Salvador Allende, a Socialist supported by the Communists. Ibáñez began his administration cautiously, chiefly in order to vindicate himself before the people for the dictatorial policies of his previous administration.

CHILE MILL, chil'è (also **CHILI MILL**), a large edge mill for pulverizing ore as a preliminary to securing the values (metal content). In these machines vertical rollers run in a circular enclosure or die. The rollers and dies are usually of steel, although stone was formerly in use.

CHILE NITER or **CHILE SALTPETER** or **CHILEAN NITRATE**. See **NITRATE OF SODA**.

CHILI, chil'i (also **CHILLI** or **CHILE**), the common name for the plant *Capsicum frutescens* (see **CAPSCUM**), or for its fruits which are used to make red, or cayenne pepper, chili sauce, chili vinegar, so-called Tabasco sauce, and a variety of peppery dishes. In the United States the best-known of the latter is chili con carne, a stew of meat, beans, minced chilies, and other spices. Its name, originally Spanish, means "chili with meat."

The many varieties of *C. frutescens* produce peppers which may be round, conical, or elongated in shape, and red, yellow, or purplish in color. Their flavor varies from mild to acrid. The term chili is usually understood as referring to the pungent variety, especially to an elongated red pepper from 3 to 12 inches in length.

CHILIASM, kil'i-áz'm. See **MILLENNIUM**.

CHILKAT INLET, chil'kät, inlet, Alaska. It extends inland for about 15 miles in a northwesterly direction from the head of the fjord called Lynn Canal (about 65 miles north-northwest of Juneau) to the mouth of Chilkat River.

CHILKO LAKE, chil'kō, lake, British Columbia, Canada, located in the Coast Mountains at an elevation of 3,842 feet in the southwestern section of the province. Chilko is long and narrow in shape, with an area of 75 square miles. Its waters exit at the northern end by Chilko River, which flows northeastward into the Chilotin, an affluent of the Fraser.

CHILKOOT INLET, chil'kōöt, inlet, Alaska. It extends inland for about 20 miles to the north and north-northwest from the head of the fjord called Lynn Canal about 65 miles north-northwest of Juneau. Taiya Inlet, on which Skagway is located, is an arm of Chilkoot Inlet, extending from Haines for about 12 miles to the north-northeast. Chilkoot Inlet was the approach to Chilkoot Pass and the Yukon River during the gold rush to the Klondike region starting in the 1890's.

CHILKOOT PASS, a pass over the Coast Mountains between Alaska and British Columbia, Canada. It is about 20 miles north of Skagway. Following the discovery of gold in the Klondike ... 1896, Chilkoot Pass was traversed by thousands of gold seekers on their way to Dawson, the principal starting point for the Klondike region. The trail they followed starts from Dyea, at the head of Taiya Inlet, and crosses the

Pass at an elevation of 3,500 feet, to the head of Lake Lindeman, a total distance of 28½ miles. From the latter place to Dawson City is 548 miles. The Chilkoot Pass route is the old trail used for generations by the Indians, and for many years was the only one taken by miners and prospectors to reach the interior. It is by far the shortest route to the Yukon. The difficulties and dangers attending this route are many, and the steepness and roughness of the ascent have proved fatal in numerous instances, to those unaccustomed to endure hardships. The summit of the Pass is 13 miles from Dyea, the first six miles being traversed by a good wagon road. Owing to the winding of the Dyea River that stream had to be crossed several times by ford or ferry. The trail then enters a narrow cañon with steep, rocky sides, which it follows to Sheep Camp, four and a half miles farther on, which point is the timber line. From Sheep Camp to the summit the rise is from 1,800 feet in three and a half miles, to 1,000 feet in half a mile, and here masses of broken rock make the ascent, which is in some places almost perpendicular, difficult and hazardous. As a general route to the Klondike and to the country over the mountains Chilkoot Pass has been superseded by the railway through White Pass.

CHILLAN, chēl-yān', Chile, capital of the province Nuble, about 56 miles northeast of Concepción. It consists of an ancient and a modern portion, the former built by the Spanish conquerors, who made it a place of some strength, in which the early settlers often found an asylum when hard pressed by the Araucanians. The old town was founded in 1579, and destroyed by an earthquake in 1835. The new town was built shortly after the latter date. It is regularly built and has a Franciscan missionary church and a normal school. To the southeast are sulphur baths, which were discovered in 1795, and to the east is the volcano of Nevado de Chillán, 9,528 feet high. Pop. 34,269.

CHILLED IRON, iron cast in metal molds called chills, where, on account of the rapid conducting of the heat, the iron cools more quickly on the surface than it would do if cast in sand. The effect of this chilling is to leave the interior of the casting soft and tough while the surface is hardened. This property of iron is taken advantage of by iron founders to harden specified parts of castings, those parts of the molds being of iron while the rest is of sand. It is used in making axle-boxes, hubs, plow-shares and some hammers and anvils. The iron selected for making chilled castings should be entirely free from silicon which interferes with the hardening, and it should have a comparatively small content of carbon. Minute percentages of sulphur and manganese, on the other hand, contribute to the desired result.

CHILLIANWALLA, Battle of, an engagement in India between the Sikh forces in considerable strength, and the British commanded by Lord (afterward Viscount) Gough, fought 13 Jan. 1849. The Sikhs were completely routed, but the loss of the British was very severe: 26 officers were killed and 66 wounded, and 731 rank and file killed, and 1,446 wounded. The Sikh loss was 3,000 killed and 4,000 wounded. On 21 February, Lord Gough

attacked the Sikh army, under Shere Singh, in its position at Goojerat, and the whole of the enemy's camp fell into the hands of the British.

CHILLICOTHE, chīl-i-kōth'ē, city, Missouri, and Livingston County seat; altitude 773 feet; on the Wabash; Chicago, Milwaukee, Saint Paul and Pacific; and the Chicago, Burlington and Quincy railroads; 87 miles northeast of Kansas City. It is in an orchard, farming, and livestock area with coal deposits and road gravel pits. The chief manufactures include tile, hardwood lumber, gloves, other farm machinery, and barbers' supplies. The city has a hospital, a state industrial school for girls, and a public library. It was settled about 1830 and incorporated in 1855. Pop. (1950) 8,694.

CHILLICOTHE, city, Ohio, and Ross County seat; altitude 643 feet; situated in the foothills of the Allegheny Mountains overlooking the Scioto River valley, above which rises in the background Mount Logan; and on the Scioto River and Paint Creek, about 40 miles south of Columbus, the state capital, and 96 miles east of Cincinnati. It is served by the Baltimore and Ohio; Norfolk and Western; and Chesapeake and Ohio railroads; also is on a network of modern state and federal highways. It is an industrial city and the business center of a fertile farming and grazing district which produces a wide variety of agricultural products; hog, cattle, and wheat raising and dairying are the leading sources of farm income. The city has railroad shops, printing and publishing, and manufactures of paper and paperboard, shoes, aluminum ware, dairy and other food products, beverages and liquors, millwork, furniture, chemicals, concrete and other products. Its cultural and recreational facilities include a modern public school system, parochial schools, a junior college (branch of Ohio University), a Carnegie public library, the Ross County Historical Society Museum, amusement centers, parks, playgrounds, lakes, and golf courses. Among the landmarks of the city are "Adena," home of Gov. Thomas Worthington, designed by Benjamin H. Latrobe, now a state memorial; and the building, erected in 1798, used by Arthur St. Clair as headquarters while governor of the Northwest Territory. Chillicothe, first incorporated in 1802, has councilmanic government. At Camp Sherman about five miles north of the city the United States government maintains an Industrial Reformatory, a Veterans' Hospital, and Mound City Group National Monument.

History.—The site of what is now Chillicothe was first settled by Nathaniel Massie and others from Kentucky and Virginia in 1796, the settlement being called Chillicothe (Indian for town). In 1800 Congress made Chillicothe the seat of government of the Northwest Territory. With the admission of Ohio to the Union as a state in 1803 it served as the state capital from 1803-1810 and from 1812-1816, when the capital was transferred to Columbus. Its daily newspaper, the Gazette (1800), is the oldest continuously-published newspaper published west of the Alleghenies. Since the beginning of the 19th century, Chillicothe has experienced a slow but solid growth based upon the development of the natural resources of the vicinity; industry, agriculture, and trade have been the

major contributing factors towards its economic progress. During World War I, Camp Sherman, training center for 50,000 recruits, was situated just outside the city. The celebration of Ohio's 100th anniversary as a state was held in Chillicothe in 1903, and in 1912 the fourth Constitutional Convention of the state met here for one session. Pop. (1940) 20,129; (1950) 20,121.

CHILLINGHAM WHITE CATTLE.

See WHITE CATTLE.

CHILLINGWORTH, William, English Anglican divine and controversialist: b. Oxford, October 1602; d. Chichester, Sussex, Jan. 30, 1644. He was matriculated at Trinity College, Oxford, in 1618, and in 1628 was made a fellow of the same college. Having been won to the Roman Catholic Church through the arguments of the Jesuit, John Fisher, Chillingworth entered the English college at Douai (Douay) where William Laud, then bishop of London, by correspondence implanted in his mind doubts regarding the foundation of the Roman Catholic system; and, having resolved to make a thorough investigation, Chillingworth returned to England in 1631 after a few months abroad. The result was that he declared for Protestantism and in 1634 set forth, in a treatise that was not published and is now lost, the grounds of his conclusion. Laud procured his nomination to a church benefice in 1635, but Chillingworth's scruples about subscription to the 39 articles and acceptance of the Athanasian Creed was an obstacle that could not then be overcome. In 1638 was published his great work, *The Religion of Protestants a Safe Way to Salvation*. In the preface he explained away his former scruple about the 39 articles, and that same year was named prebendary and chancellor of Salisbury.

CHILLIWACK, town, British Columbia, Canada, on the Fraser River, 64 miles east of Vancouver on the old Yale road, now a link of the Trans-Canada highway. It has canning, lumber, and furniture plants along with other minor industries. A dairying, livestock, and fruit and tobacco growing area surrounds the town which has 6 churches, public and high schools, a hospital, a weekly newspaper, a library, and four banks. It is served by the British Columbia Electric and the Canadian National railways, an airport, and a ferry to the Canadian Pacific Railway at Agassiz. Pop. (1951 est.) 4,000.

CHILLON, shē-yōn' or shī-lōn', castle, Switzerland, on Lake Geneva, six and one-half miles southeast of Vevey, once an important stronghold of the counts and dukes of Savoy, and the prison house of François de Bonnavard, prior of Saint Victor, Geneva, from 1530 to 1536. It stands on a rock rising 22 yards from the shore of the lake, and is reached by a bridge. It probably dates from the 9th century. Bonnavard was confined in it by Duke Charles of Savoy because he had assisted the republic of Geneva, with which the duke was at enmity. Lord Byron's poem, *The Prisoner of Chillon*, founded on this incident, has made it well known.

CHILOE, chē-lō-ā', province, Chile, consists of the island of that name on the west coast, part of the mainland lying beyond the narrow Strait of Chacao on the north and the Gulf of Corcovado 30 miles wide on the east, and of

a number of neighboring islets, mostly uninhabited; area 9,052 square miles. The island of Chiloé is 115 miles long, 45 miles wide; area 4,700 square miles. Chiloé Island is hilly in the interior, and everywhere covered, except immediately along the shores, with nearly impassable forest. The climate is mild and not unhealthy, although inordinately wet, with an average of only 51 sunny days per year. The Indians belong to a subdivision of the Araucanian family. Timber and coal are at present the chief exports from the island though the exports are very small. In the eastern part the soil is fertile and well cultivated. Corn, wheat, barley, and hemp are produced extensively and domestic animals are plentiful. Oysters, which are very scarce elsewhere in South America, are found in large quantities in the Chiloé Archipelago. The potato here, as in other parts of South America, grows wild. The Spaniards discovered the archipelago as early as 1558. Chiloé was the last part of Spanish America under Spanish rule, which it was not rid of until 1826. The capital and chief seaport, Ancud, on the north coast of the island has a good harbor, is the seat of a bishop and has a population of about 13,981. Pop. of province (1943 est.) 91,355.

CHILON, kī'lōn, son of Damagetus and one of the so-called Seven Wise Men of Greece. He flourished about the beginning of the 6th century B.C., and was a native of Sparta, and one of the ephori, a body of magistrates which he is said to have originally introduced. Chilon claimed that the great virtue of man was prudence or a proper judgment as to coming events.

CHILOPODA, ki-lōp'ō-dā, one of two principal divisions of Myriapoda, represented by the centipede (q.v.). In these animals the body is composed of from a few to between 100 and 200 segments; the body is flattened, and there is but a single pair of legs to each segment. There are three pairs of mouth appendages; that is, a pair of jaws succeeded by two pairs of accessory jaws; while the first pair of legs are modified to form the poison fangs, which contain at their base a poison sac, the ducts from which open by a minute pore, out of which the blood oozes when the creature bites. The Chilopoda are divided into four families—Lithobiidae, Scolopendridae, Geophilidae and Scutigerae.

CHILPERIC, chīl'pēr-īk, two Merovingian kings: (1) **CHILPERIC I**, king of Neustria from 561 to 584. He never was acknowledged king of all the Frankish land, but divided the kingdom with his three half-brothers; he had, however, great power throughout their dominions by reason of his influence with the nobles. The murder of his wife, Galswintha, involved him in a war with her brother-in-law, Siegbert of Austrasia. (2) **CHILPERIC II**, king of Neustria from 715 to 720. He was several times at war with Charles Martel (q.v.), but was forced to submit to him, and was in 719 made king of the Franks.

CHILTERN HILLS, a range of flint and chalk hills in England, extending through Oxford, Bedford, and Buckingham shires; loftiest summit, about 850 feet. These hills were anciently covered with forests, and were infested by numerous bands of robbers. The steward of the Chiltern Hundreds is an officer of the

crown, appointed to protect the people of Buckinghamshire from the robbers of the Chiltern Hills. This office is now a sinecure, but as a member of Parliament can only resign his seat by accepting office, he accepts this sinecure, which he immediately vacates for the benefit of others.

CHILTERN HUNDREDS. See **CHILTERN HILLS**.

CHILTON, Eleanor Carroll, American writer: b. Charleston, W. Va., Sept. 11, 1898. She was the daughter of William Edwin Chilton (1858–1939), a United States senator. After graduating at Smith College in 1922 she went to England to study medieval literature in Oxford and London, and following her return to the United States she published a novel, *Shadows Waiting* (1926). Shortly thereafter she went back to England, where she continued to write stories, plays, and novels. In collaboration with Willis Fisher and Herbert Agar she published a volume of poems entitled *Fire and Sleet and Candlelight* (1928), and with Herbert Agar, *The Garment of Praise* (1929), a collection of essays; and she also published another novel, *The Burning Fountain* (1929). She was married to Herbert Agar in 1933, and the following year they returned to the United States, going to Louisville, Ky., where he was editor of the *Courier-Journal*. Her next novel was *Follow the Furies* (1935).

CHILTON, city, Wisconsin, seat of Calumet County, located on the Manitowoc River 18 miles east of Oshkosh and 8 miles east of Lake Winnebago; it is served by the Chicago, Milwaukee, St. Paul and Pacific Railroad. The city is the center for an agricultural region producing milk, barley, peas, wheat, cattle, corn, cheese, and butter. There are malt and milk condensing plants, a canning factory, aluminum and fertilizer plants, and bottling works. Chilton was founded by a Negro, Moses Stanton, and his Indian wife, a descendant of King Philip. It is governed by a mayor and board of aldermen. Pop. (1950) 2,367.

CHILWA, chil'wā, a lake in Nyasaland Protectorate, on the border of Mozambique and south-east of Lake Nyasa. The length is about 40 miles, but the lake's area varies with the rainfall. David Livingstone discovered the lake in 1859.

CHIMAERA, ki-mēr'ā, in ichthyology, one of a family of oceanic, elasmobranch fishes, Chimaerodae, of primitive structures, a few species of which survive from Cretaceous and Lower Eocene time; noted for their extraordinary appearance. They are small, no living species exceeding three feet. Chimaera have a shark-like body, and heads furnished with strange fleshy projections, especially in the male, where they serve as "claspers"; or the snout may be extended into a sharp beak. The tail is continued into a sort of whip, often nearly as long as the body. One species is frequently caught in the North Atlantic, and others exist in the North Pacific and in the South Seas. Most of them inhabit deep water, where the young are born from eggs laid in leathery cases, like those of rays, on deep bottoms. See also **CHIMERA**.

CHIMAEROIDEI, ki-mē-roi'dē-i, in zoology, one of the primary divisions of fishes, the

equivalent of Holocephali (q.v.).

CHIMANGO, chē-māng'gō, a carrion hawk of South America (*Ibycter chimango*), closely related to the Caracara (q.v.). The plumage is black, with whitish streaks on neck and breast in the adult, which are lacking in the young. Chimangos are particularly numerous in the Falkland Islands. Charles Darwin describes them as without fear of man, frequenting inhabited regions and feeding on all kinds of refuse.

CHIMAY, Princesse de. See **TALLIEN**, JEANNE MARIE IGNACE THÉRÈSE.

CHIMAY, shē-mā', town, Belgium, in Hainaut Province 30 miles southwest of Dinant. Only one of the seven towers of the ancient castle is still extant. Jean Froissart, the French chronicler, was buried at Chimay about 1400. Faience is manufactured, and marble is quarried in the vicinity of the town. Chimay was founded in the 7th century. Pop. (1941) 3,368.

CHIMBAI, chīm-bi', town, Soviet Union, in the Uzbek Soviet Socialist Republic, is located in the delta of the Amu Darya, south of Lake Aral. It was formerly the capital of the Kara-Kalpak Republic. Pop. (1926) 5,720.

CHIMBORAZO, chīm-bō-rā'zō, a peak of the Andes in west central Ecuador, in Quito Province. It has a height of 20,702 feet, and is the highest point in the Cordillera Real. The top is covered with perpetual snow. The mountain has no crater, though it is built of volcanic rock. This mountain was ascended in 1802 by Baron Alexander von Humboldt and Aimé Jacques Alexandre Bonpland who, though they failed to reach the summit, yet mounted to the great height of 19,390 feet, a greater elevation than ever was before attained by man. Their further ascent was prevented by a chasm 500 feet wide. In 1880 the summit was reached for the first time by Edward Whymper, who made two ascents of the mountain.

CHIMERA or **CHIMAERA**, ki-mēr'ā, in Greek mythology, a fire-breathing female monster reported to be of divine origin, brought up by Amisodarus, king of Caria. According to the description of her given in the Homeric poems, the fore part of her body was like that of a lion, the middle like that of a goat and the hind that of a dragon. She laid waste the fields of Lycia and all the country round. Hesiod says she had three heads, one for each of the three animal parts composing her body. She was destroyed by Bellerophon with the help of Pegasus. This mythical monster is supposed to have had its origin in the volcano of the same name, near Phaselis, in Lycia, round the top of which, according to popular belief, dwelt lions, round the middle goats, and at the foot poisonous serpents. The word Chimera early came to be used for a wild dream, owing to the strange, unnatural form of the being described by the poets.

CHIMES. A set of bells from 3 to 12 in number, generally of considerable weight, tuned to the notes of the diatonic scale with sometimes one or two additional half tones. In England these are most often hung "free," that is, so as to swing, and then are called also a "ring"

or "peal." A set of bells tuned to the chromatic scale, with a compass of three or more octaves and hung "fixed" or "dead," i.e., so as not to swing, is called a carillon. Tunes are played automatically on chimes where the bells are hung fixed and on carillons by a revolving drum and hammer mechanism like that of a music box. A chime hung fixed is also played by a chimer, who with his hands operates the levers of a chiming-stand, one lever for each bell. A carillon is also played by a carillonneur who uses both hands and feet on keyboards similar to those of an organ, connected with the clappers. In England a method of playing upon bells hung free, called "change-ringing," has long been in vogue. In this method each bell is separately swung by means of a rope by an individual ringer. The bells are thus made to sound one after another in mathematically defined changing sequences until they come back to the order in which they started. This in complicated changes often involves several hours of ringing. Great expertness is shown by companies of men in this art but the product of their skill is a regularly developed mosaic of sounds rather than music. On chimes only a few simple tunes can be accurately played. On a carillon, however, the chromatic characteristic combined as it is with the extended compass and range in the size of the bells—from several tons to a few pounds—enables the master of its keyboard to play not only the notes of a great variety of music but to interpret sentiment, and produce effects beyond the power of any other musical instrument. While England, because of its many bells, has been poetically called "the ringing isle," bell music has been still more a characteristic of Belgium and Holland and French Flanders through centuries. There carillons, and the great church and town hall towers which contain them, are maintained entirely at the public expense, and the bell music of folk songs, patriotic airs and national hymns, heard day and night and on market and feast days, is a considerable feature in the life of the people. Summer evening concerts in the Low Countries when the city carillonneur plays on the carillon clavier always have brought hundreds together to listen. Such concerts by Josef Denyn, the unrivalled master of the art, on the finest carillon in the world at Mechlin, Belgium, 45 bells, attracted thousands before the Great War. Antwerp's carillon then numbered 47 bells, Ghent's 52, Bruges' 47, Courtrai's 49, Mons' 47. In all there were recently about 70 carillons in Belgium and northern France. In Holland there are also about 70; among the finest are Middleburg, 41 bells; Delft, 40; Amsterdam (Palace), 37; Utrecht, 42; Arnhem, 47; The Hague, 37 and Appingedam, 25. Carillon destruction by Germany has undoubtedly been great. The bells of Ypres, 44; of Termonde, 40 and of Saint Peter's at Louvain, and of Arras are destroyed, and probably many or possibly all others in the occupied regions. The oldest chimes in the United States are those of Christ Church, Philadelphia; Christ Church, Boston; and Trinity Church, New York. California University, Berkeley, has 12 fine bells. Among English Carillons are Cattistock, 35 and Eaton Hall, 28 bells. In Ireland, Queenstown Cathedral has a carillon of 42 bells—the finest bells

in the United Kingdom. Where chimes and carillons originated is not known. Tradition takes us back to the 12th century and the abbey of Egmond in Holland. But it is not until early in the 16th century that authentic records, principally in certain Low Country towns, appear. Louvain had 8 bells in 1525; Hoorn, 10, in 1528; Oudenburg 10, in 1539; Alkmaar 11, in 1541; Ghent 16, in 1543. Thereafter the development of this musical instrument was rapid. D. G. Rossetti, Thackeray, Stevenson, George Macdonald, Thomas Hardy, Victor Hugo, Georges Rodenbach, DeAmicis and others have written of carillon music. Longfellow's 'Belfry of Bruges' is especially well known. Consult Rice, William Gorham, 'Carillon Music and Singing Towers of the Old World and the New' (1925); Coleman, S. N., 'Bells' (1928); Robinson, F. E., 'Among the Bells' (London 1909); Starmer, W. W., 'Royal Academy of Music Lectures' (London 1916); Price, F. P., 'Carillon' (New York 1933); Morris, E., 'History and Art of Change Ringing' (London 1937).

WILLIAM GORHAM RICE.

CHIMES OF NORMANDY, The (Les Cloches de Corneville), opera comique in three acts by Robert Planquette, libretto by Clairville and Gabet, first produced at Paris, 19 April 1877. While called an opera comique, 'The Chimes of Normandy' is rather in the operetta class, the most typical of which are Offenbach's famous series of *operas bouffés*. The story is simple and romantic, if not vital. The music is unaffected and spontaneous and its first success, which was conspicuous even for those days and for audiences which saw many a popular hit, has been repeated wherever the opera has been given. The legend of the chimes is the best known number, but there is scarcely a dull moment in the entire work and half a dozen of the songs are household favorites the world over. The lilting barcarolle, "On billow rocking," the cider song, the waltz song in the last act "That night I'll ne'er forget" and the spritely finales of the first and second act come readily to mind.

LEWIS M. ISAACS.

CHIMNEY (Fr. *cheminée*, related to Latin *caminus*, oven), an upright structure of stone, brick, etc., enclosing one or more flues or passages through which smoke and gas from the fire in a stove, furnace or fireplace may escape into the open air. Originally the term chimney included both the fireplace and the shaft. How far the Greek and Roman architects were acquainted with the construction of chimneys such as we have is a matter of dispute. That kitchens and baths were provided with chimneys appears certain, but how far other apartments were so provided is doubtful. An ancient mosaic found in Algeria, and representing a Roman country mansion, shows chimney stacks projecting above the roof. Of course in southern Europe fires are less necessary than in northern Europe. Chimneys require much attention to make them secure and prevent their smoking, so great an annoyance to domestic comfort. It seems at present to be acknowledged that it is much better to exclude the cold, damp air from the flues, by narrowing the aperture at the top, than to give larger

vent to the smoke at the risk of admitting a quantity of air to rush down the flue. For this reason chimney pots are of great use. The longer a chimney the more perfect is its draft, because the tendency of the smoke to draw upwards is in proportion to the difference of weight between the column of air included in a chimney, and an equal column of external air; and the heated air in the chimney being lighter than the external air, the longer the chimney is the greater is this difference. Short chimneys are liable to smoke, and fireplaces in upper stories are therefore more apt to smoke than those in the lower ones. Two flues in the same chimney should not communicate with each other short of the top. In manufactories tall chimneys are built for the purpose of carrying away the great quantities of smoke, which would otherwise be highly deleterious to the health of those living in the neighborhood. In chemical works, especially, these chimneys are sometimes built to an immense height. Such chimneys are constructed from the inside, by which the expense of the scaffolding is saved. The shafts of most early chimneys were round and the chimneys contained but one shaft each, from the side of which the smoke generally issued, the top being crowned. In France and Italy chimneys came to form a decorative part of the national architecture.

CHIMNEY SWALLOW, *chīm'nī swōl'ō*, the common swallow of Europe (*Hirundo rustica*), so called in Great Britain, where it makes its nests about buildings and in niches in the outside of old chimneys. They are migratory. (See SWALLOWS.)

In the United States the name is given erroneously to the chimney swift, which is similar to the swallow in general appearance and feeding habits, but different from it in structure. The chimney swallow cements its nest together with saliva and attaches it to the rough inside wall of the chimney, from five to ten feet from the top. Since the nests are shallow and not very secure, they sometimes become detached and fall down the chimney. See also SWIFTS.

CHIMPANZEE, *chīm-pān-zē'*, one of the four anthropoid or manlike apes (the others being the gorilla, orangutan, and gibbon). Native to the equatorial forests of Africa north of the Congo, from about 800 miles north to 500 miles south of the equator, and from the Atlantic to somewhat east of the Nile, chimpanzees are usually found in groups of six to a dozen individuals. They are equally at home in trees and on the ground, being more arboreal than the gorilla, much less so than the gibbon. At night they sleep in tree nests, each animal (except infants) constructing a new nest every evening. Their diet is mainly herbivorous, but it seems probable that they occasionally eat bird eggs and insects. Although very strong, agile, and capable of inflicting heavy damage with their teeth, chimpanzees are rather timid and try to avoid combat with man and other animals. They are noisy creatures, vocalizing loudly, stamping, and drumming on the trunks of trees. Such exhibitionistic and bluffing behavior probably often substitutes for actual fighting.

The average weight of the adult chimpanzee is about 115 pounds, with a range of from around 90 to 180 pounds. Males are usually somewhat larger than females. The animal stands approxi-

mately 4½ feet high and has a maximum arm spread of 6 feet. By comparison with man, the arms are long, the legs are short and slightly bent at the knees. The chimpanzee can stand and walk upright, but more usually it moves on all fours, the body weight then being supported on the soles of the feet and on the back of the second joints of the fingers. The bony ridges above the eyes are very prominent, the nose and thumbs are small, the ears are large. The teeth, especially the canines, are relatively large but are of the same kind and number as in man. Most of the body is covered with black hair which may become gray or brownish with age. The skin of the ventral trunk is very light in color; exposed areas, notably the face, hands, and feet become almost black with increasing age and exposure to sunlight.

The newborn chimpanzee weighs about 4 pounds and, except for the ability to cling tightly to its mother, is about as helpless as a human infant. For the first 8 months or longer, mother's milk is its only food, and it may continue to suck at the breast until the end of the second year. Adult stature is attained at about the age of 12 years. Puberty occurs at approximately 9 years. The female has a sexual cycle, averaging 35 days in length, which is characterized by a prominent swelling of the light colored external genital area. Mating usually occurs only during the 10 days or so of maximal tumescence, which occurs midway between successive menstruations. The period of pregnancy is about 8 calendar months. Single births are the rule; twins occur infrequently. The life-span is estimated to be 50 years, but this probably is often shortened by disease or accident.

Because of their physical similarities to man, the apes (Pongidae) are generally assumed to be closely related to man in evolutionary development. Behavioral resemblances to man are especially conspicuous in chimpanzee; this ape is also available in larger numbers and is more adaptable to captivity than the other anthropoids. Chimpanzees are therefore used extensively in biological research, particularly in the study of behavior and its neurological foundations. The brain of chimpanzee resembles that of man in its proportions and patterns of fissurization, but is less than half as large. Sensory capacities are closely similar to those of man. In general, the behavior of chimpanzees is determined more by learning and individual experience, and less by inborn organization (instincts), than is that of lower mammals. Their memory is good, and they exceed most other animals in problem-solving abilities. As compared to man, their intellectual limitations are related to a deficiency in symbolic representation. They communicate by sounds, postures, and gestures, but do not have a language in the usual sense. This lack presumably is responsible also for the almost complete absence of social inheritance, or culture. Resemblances to man are even more pronounced in the wide range of emotional expression, and in sensitivity to their social environment, than in respect to intelligence.

The foregoing account probably applies to most of the varieties or races of chimpanzee which, by some authorities, are classified as separate species on the basis of superficial differences of pigmentation, hair patterning, and so on. There is a little known and rare pygmy chimpanzee, *Pan paniscus*, which may constitute a

separate species; it lives south of the Congo, and is about half as big as some of the other better known types.

HENRY W. NISSEN,
Associate Director, Yerkes Laboratories of Primate Biology.

CHIMU, ché'mōō, the name given to two periods of the pre-Incan civilization of Peru. The first, known as Mochica or Early Chimu, flourished from about 500 to 800 A.D. The pottery from this period, particularly the portrait jars modeled in the form of human heads, is remarkable, and there also survive fine examples of metalwork in copper and gold alloys. By means of irrigation and the terracing of hillsides sufficient food was raised to support a highly developed urban civilization.

This culture was absorbed by the Tiahuanaco after 1000 A.D., but a new Chimu culture, known as Late Chimu, subsequently emerged in the north. It in turn was absorbed by the Incas in the 15th century. See also *ARCHAEOLOGY—New World*; *PERUVIAN ARCHAEOLOGY*.

CHIN. See **KUKI-CHINS**.

CHIN, jīn (KIN), the name of a Jurchen dynasty which ruled northern China from 1115 to 1234 A.D. It rose to power by conquering the Khitan state of Liao, exacted tribute from the Sung emperors, and was finally overthrown by the Mongols. Through their contacts with Sung China the Jurchen gradually adopted Chinese civilization.

CHIN, jīn, or **TSIN**, the name of several Chinese dynasties: Western Chin (265–317 A.D.) and Eastern Chin (317–420 A.D.), of the Six Dynasties period; and Later Chin (936–946 A.D.), of the Five Dynasties period.

CH'IN, chīn, or **TS'IN**, the dynasty which ruled China from 221 to 207 B.C. It succeeded the Chou and was followed by the Han. During this period the greater part of the country was unified, feudalism was abolished, the government was reorganized, and great public works were undertaken. See also **CHINA—The Land, the People, and Their History**.

The name Ch'in is also applied to three minor foreign dynasties which ruled over limited parts of China during the Six Dynasties period: Early Ch'in (351–394 A.D.), a Mongol dynasty in Shensi; and part of Central Asia; Later Ch'in (384–417 A.D.), a Mongol or Tibetan dynasty in Shensi; and Western Ch'in (385–390; 409–431 A.D.), a Turkic or Mongol dynasty in Kansu.

CHIN FLY, a horse botfly (*Gastrophilus nasalis*) which has been confused with the horse bot (*Gastrophilus equi*). This species is smaller than the bot, very hairy, and has a rust-colored thorax. The abdomen is whitish at the base, and the wings are not spotted. It deposits its white eggs on the hairs about the lips or in the nostrils of equine animals, and it is probable that the maggots hatch out more promptly than in other species.

CHIN HILLS, mountain range and district of northwestern Burma. The mountains are from about 5,000 to 8,000 feet high and run generally in a north and south direction, inter-

persed by narrow valleys. They are occupied by part of the Chin tribes (see **KUKI-CHINS**). The district to which they lend their name has an area of 10,377 square miles.

CHINA, chī'ná, a republic since 1912, anciently known to the Western World as CATHAY, is the largest political subdivision of Asia, comprising the major part of the southeastern area of that continent. The natural features of China, its economy, social and political life, history, and culture are treated under the following headings:

- | | |
|---|-------------|
| 1. The Land, the People,
and Their History | 4. Drama |
| 2. Language | 5. Music |
| 3. Literature | 6. Art |
| | 7. Ceramics |

1. THE LAND, THE PEOPLE, AND THEIR HISTORY. China stretches from the center to the eastern extremities of Asia, extending from latitude 53°35'N. to 15°48'N. (Paracel Islands), and from longitude 73°31'E. to 135°2'30"E. It is bounded on the north by Siberia and the Mongolian People's Republic; on the west by Russian Turkestan, Russian Pamir, Afghanistan, and India; on the south by India, Nepal, Bhutan, Burma, Laos, Viet Nam, and the South China Sea; and on the east by Siberia, Korea, the Yellow Sea, and the East China Sea. Its greatest length is about 3,000 miles from west to east; its greatest breadth, about 2,000 miles. The total area is 3,759,115 square miles, usually divided into the 18 provinces of China Proper, Manchuria, Inner Mongolia, Sinkiang, Tibet, and Formosa. In 1949, the officials of the new People's Republic of China announced a plan for dividing China's huge territory into six administrative regions.

In addition to the 18 provinces south of the Great Wall, known to geographers of the 18th and 19th centuries, there are the provinces of Sikang, Chinghai, and Ningsia on the west, and Suiyuan, Chahar, and Jehol on the north, all of which were created in 1928 or 1929, and the 9 provinces of Manchuria, besides the province of Sinkiang (created in 1884), the special territory of Tibet, and the island of Formosa, which became a province in 1945.

The region of China Proper lies in the southeastern part of the republic and occupies 1,373,370 square miles, approximately 36.5 per cent of the whole area. In general, the northern boundary corresponds with the 1,250-mile Great Wall, stretching across mountain and valley to cut off Mongolia. To the west lie the provinces of Chinghai and Sikang and the Union of Burma; to the south, Laos and Viet Nam. Though the 18 provinces occupy little more than one third of the whole territory, they have 86 per cent of the population.

Manchuria, known under Japanese occupation as Manchukuo, consists (since 1945) of the nine provinces of Liaoning, Antung, Liaopoh, Kirin, Sungkiang, Hokiang, Heilungkiang, Nunkiang, and Hsingan, which lie, roughly, between the Khingan Shan and the Siberian maritime province and extend from Jehol and Korea on the south to the Amur River on the north. In Manchuria's 413,306 square miles live 38,584,268 people (1947 estimate), nearly one third of whom are in Liaoning.

Mongolia, a high plateau around the Gobi Desert, is divided politically into the Mongolian People's Republic (Outer Mongolia), which is influenced politically by the USSR; the Tuvian Autonomous Region of the Soviet Union; and the

Chinese provinces of Chahar, Ningsia, and Suiyuan, which are known as Inner Mongolia. The republic, governing a territory of 625,946 square miles and an estimated population of 880,000, was set up in 1924; China maintained nominal sovereignty until the Sino-Russian treaty of Aug. 14, 1945, by the terms of which it became independent.

Sinkiang, now considered a province, is an immense territory of 660,976 square miles with a population of 4,012,330 (1947 estimate). A land of high mountains and deserts, most of the inhabitants live in the Ili River valley or in the oases watered by the Tarim River. Tihwa

line of China, forming a large, somewhat irregular curve, extends in the north from the mouth of the Yalu River in Antung to Tunghing in Kwangtung, a distance of 5,362 miles. The southern half of the coastline is not deeply cut by indentations, but there are numerous good harbors. In the north two peninsulas, Shantung and Liaotung, project to cut off the Gulf of Pohai. Except for the two peninsulas, the shore is low and the soil is alluvial in nature as far south as the Bay of Hangchow. From there to Canton the shore is, in general, rocky and of granite formations, but southwest of Canton it again becomes lower. Numerous islands of all sizes lie along

Table 1—AREA AND POPULATION OF CHINA (1947)

Provinces	Area (in square miles)	Population ¹	Density (per square mile)
Anhwei ..	54,319	21,705,256	399.6
Chekiang ..	39,632	19,942,112	503.2

Total, China	3,759,115	461,406,285	122.7

¹ Official estimate, mid-1947.

² Estimate by Chinese government.

(Urumchi) is the capital; other important cities are Hami (Qomul), Shufu (Kashgar), and Soche (Yarkand). By reason of its border location contiguous to the Soviet Union, Sinkiang is developing increasing importance.

Tibet (q.v.), a high plateau, surrounded by a rim of towering mountains, has an approximate area of 469,413 square miles. The capital and chief town is Lhasa. Tibet is the source of several important rivers, including the Brahmaputra, Salween, and Indus. Up to the spring of 1950, political control by the People's Republic of China had not been established.

Table 1 gives the names of all the provinces and political divisions, their area in square miles, population, and density of population to the square mile. Population figures are for 1947. The 18 provinces of China Proper are grouped separately.

Physical Features and Climate.—The coast-

the two northern peninsulas and the southern shore, the two most important being Formosa (Taiwan), off Fukien Province, and Hainan, opposite a small peninsula of Kwangtung Province. The coast is washed by three inner seas: the Yellow, the East China, and the South China, cut off from the Western Pacific by Japan, the Ryukyu (Nansei; Loochoo) Islands, and the Philippines. Important ports are Antung, Talien (Dairen), Chinwangtao, Taku, Chefoo, Weihaiwei, Tsingtao, Shanghai, Hangchow, Ninghsien (Ningpo), Minhow (Foochow), Amoy, Swatow, Hong Kong, Canton, and Pakhoi.

In China the general slope of land is from the high mountains of Sinkiang, Tibet, and Mongolia in the west to the low coastal areas in the east. Mongolia is a high plateau, almost 5,000 feet above sea level, surrounded by great ranges of mountains. The Gobi Desert, the greater part of which is in the Mongolian Peo-

ple's Republic, lies in the center of the plateau, a steppe or grassland region too dry for anything but grazing except in the extreme south and along a few of the rivers in the north. Large areas of Sinkiang are either deserts or high mountains. The Tien Shan range cuts the province into two parts; north is the Dzungaria (Sungaria) Basin, watered by the Ili and Irtysh river systems. South of the mountains but north of the great Takla Makan desert lies the Tarim Basin, through which the Tarim River, having come down from the high mountain ranges, flows until it is finally lost in the sands after providing water for oases scattered on a line from Hami to Shufu (Kashgar). Most of the population of Sinkiang lives in these oases or in the valley of the Ili. The ancient Silk Roads both ran through Sinkiang, one north of the Tien Shan and the other, south.

Tibet, a high plateau with an average altitude of about 13,000 to 14,000 feet, has some of the highest mountains in the world forming its rim, the Kunlun Shan on the north, the Himalayas on the south, and on the east the almost impassable ranges running from Sikang south into Yunnan. Tibet is the source of the Indus and the Brahmaputra rivers, which make their way to India; and the Salween, which reaches the sea through Burma and Indochina.

Manchuria is flanked from north to south by two ranges of mountains, on the west by the Great Khingan and on the east by the Changpai; between them are broad and fertile valleys, well watered by several rivers, the chief of which are the Amur, the Sungari, the Ussuri, and the Yalu.

China Proper is bordered on the north by an arm of the Nan Shan (Chilien Mountains) which swings northeast in an arc from Tibet to Manchuria. Between this range, known under several different names, and the broken line of mountains, the Chinling Shan and others (running east and west across central China and rising to 12,000 feet in southern Shensi, 5,000 feet in western Honan, and 3,000 feet in southern Anhwei) lies the great basin of the Hwang Ho or Yellow River, a series of plains characterized by a yellowish soil called loess. This soil, which in places has a depth of 300 feet, was deposited by great winds sweeping in from the wastes of Central Asia; the region under intense cultivation grows corn, wheat, cotton, millet, and rice.

In central China is the great Yangtze Valley, an area of low plains and alluvial soil. The climate is milder than in the valley of the Hwang Ho, and there appear plants of a southern type such as the bamboo and the orange. A large population cultivates rice, tea, and cotton. The greater part of China south of the Yangtze is mountainous though there are few well-defined ranges; but one of them, the Nanling, has a few peaks rising above 6,000 feet; it extends east and west to form the northern boundary of Kwangtung. Another is the range marking the Fukien-Kiangsi border, known as the Tayu Shan in the south and the Wuyi Shan in the north. Coastal China south and east of these two ranges has a subtropical climate with characteristic vegetation.

In the southwest, Kweichow and Yunnan are both mountainous. The former, a country of deep valleys and precipitous mountains, has an average elevation of 4,000 feet. Yunnan, though 2,000 feet higher, is more plateau-like. Its mountains are quite as rugged as those of Kweichow;

but in contrast with those in Kweichow and the other provinces, Yunnan's ranges run in a north and south direction.

China has five sacred mountains: Tai Shan in Shantung, Hwa Shan in Shensi, Sung Shan in Honan, Heng Shan in Hopeh, and Heng Shan in Hunan.

Rivers and Lakes.—Three large river systems drain China: the Hwang Ho or Yellow in the north, the Yangtze in Central China, and the Si Kiang, or West River in the south. The Yellow River, which derives its name from the heavy yellow silt it carries, rises in Chinghai and flows by a circuitous route around mountain ranges through northern China to the sea. Along its 2,700-mile course the river receives many tributaries, the most important of which are the Tao, the Fen, the Wei, and the Lo. Below Tungkwan it is navigable for native boats, but steam launches can be used only 25 miles above the mouth. In the last 500 miles of its extent the river is so choked with silt that in many places its bed rises several feet above the surrounding territory, necessitating high dikes. Below Chenghsien (Chengchow) it is a wandering stream that has changed course seven times between the third millennium B.C. and 1938. In 1852-1855 the river left its old channel in northern Kiangsu and emptied into the Gulf of Pohai. In May 1938, in the course of a battle between the Chinese and Japanese in Honan, the dikes gave way and the river again emptied through northern Kiangsu. In 1947, the Chinese government, with the aid of the United States Army, diverted the river to its pre-1938 channel.

The Yangtze Kiang, China's longest river and the most important for navigation, rises in Chinghai and flows east through central China, draining an area of 756,500 square miles. Of its 3,400 miles only the last 1,000 below Ichang are easily navigable, though smaller boats are able to ascend as far as Pingshan near Ipin (Suifu). Between Ichang and Chungking are the famous Yangtze Gorges, which, because of changing water levels and rapids, are extremely difficult of navigation. Important tributaries are the Min, Kialing, Han, Wu, and the streams of the Tungting and Poyang lakes. Near Shanghai the Yangtze empties through a delta some 40 miles wide, built up by the great amount of silt the river carries.

The Si Kiang, with a course of some 1,200 miles, traverses south China. It empties into the South China Sea through several branches, one of which is the Pearl River on which stands Canton. The river is navigable to Tsangwu (Wuchow) for steamers, and native junks reach interior Kwangsi and Kweichow.

Other important Chinese rivers are the Amur with its tributaries, the Sungari and the Ussuri, and the Yalu, all in Manchuria; the Pei, on which the port of Tientsin lies; the Hwai; the Chientang with Hangchow at its mouth; and the Min, which empties at Minhow. Four other rivers, the Indus, the Salween, the Mekong, and the Brahmaputra, have their source in China but flow through Burma, India, and Indochina. The Tarim in Sinkiang is the most important river in the interior.

Although China has many lakes, few are of any considerable size. Tungting Hu in Hunan, a natural reservoir of the Yangtze, during the summer's high water is about 74 miles long but its area is much reduced in winter. Poyang

Hu in Kiangsi also drains into the Yangtze. Others are the Tai and the Hungtze lakes in Kiangsu.

Since the chief rivers of China run from west to east, the country, particularly in the more densely populated south, is intersected by a network of canals facilitating north and south communication by water. The most important of these is the Grand Canal, connecting Hangchow with Peking (Peiping); about 1,000 miles long, it was built in sections between the 5th century B.C. and the 13th century.

Climate.—China lies almost entirely in the temperate zone, but because of its position on the eastern edge of the continent of Asia, it apparently enjoys the coolest climate for its latitude in the world. Nevertheless, China is warmer than the United States and the nations of Western Europe. The climate is a result of three factors: seasonal winds, cyclonic storms, and tropical typhoons. In the winter a high pressure area centers in Siberia with a cold dry wind blowing from the northwest. Days are, in the main, bright and cloudless in north and west China, but in the Yangtze Valley and south China winter is a gloomy period. In the summer the high pressure area moves out over the Pacific, and the prevailing winds blow from the south or the southeast, heavily laden with moisture. Experiments at Nanking in 1930 and 1931 indicated, however, that both winter and summer winds did not extend above 5,000 feet. Above that altitude westerly winds prevailed throughout the year.

Superimposed on the seasonal winds are the cyclonic storms similar to the areas of high and low pressure which move across the United States. They travel from west to east across China, some apparently having formed in high Central Asia and others having originated in Europe. In the winter and spring they are most numerous in the Yangtze Valley, but in July and August they sweep across north China. Though few yield an abundance of rain, the joining of cyclonic storms moving from the west and the prevailing moisture-laden winds from the southeast is productive of rainfall. In winter the storms encounter the dry winds moving down from the northwest, causing a cold wave.

Of the typhoons of the Western Pacific, most of which originate near the Marshalls and the Carolines, four or five annually strike China's mainland. They move toward Kwangtung in May but by July and August are hitting the central coast; after October the prevailing northwest winds tend to keep them out at sea. Accompanied by rain squalls blown by a high wind, the typhoons often cause severe damage. These three meteorological factors, together with the topography and the nearness to the sea, determine the climate of any given place in China.

China has a great range of temperature from north to south which the north winds in winter and the south winds in summer tend to exaggerate. The mean January temperature for Lupin (Manchouli) is -14.8°F. and for Amoy, 56.8°F. , a difference of 70°F. The mean July temperature for Lupin is 69.8°F. and for Amoy, 84.2° , only 14° difference. Mean temperatures for both January and July rise steadily from Peking southward along the coast: Peking, 23.7° and 79° ; Tsingtao, 29.5° and 74.5° ; Shanghai, 37.7° and 80.8° ; Nanking, 36° and 82° ; Hangchow, 39.2° and 83° ; Canton, 55.5° and 83.5° .

The interior cities of Sian, Hankow, Chungking, and Changsha have a mean July temperature about the same as Amoy, but the mean January temperatures fall considerably lower, to 30.6° in Sian and 46° in Chungking. The heat and relatively high humidity makes China south of the Yangtze uncomfortable in summer.

With moisture-laden winds blowing from the south and southeast, the greatest rainfall occurs in the coastal provinces in that section of China. Canton has 65 inches annually; Hangchow, 58; Shanghai, 44; and Nanking, lying inland, 38. To the north the rainfall steadily decreases with 25 inches at Peking, 21 at Pinkiang (Harbin), and 14 at Lungkiang (Tsitsihar). Lupin, on the western side of the Great Khingan Shan, has only 9 inches a year. The Yangtze Valley has sufficient rainfall (Chungking gets 43 inches annually), but the Hwang Ho Valley, cut off on the south by the Chinling Shan, has a precipitation of only 20 to 25 inches a year. Large parts of Mongolia and Sinkiang are deserts, but Tihwa (Urumchi) in northern Sinkiang has 13.5 inches of rainfall a year. Snowfall is, in general, light in China because the winter months are dry; rare in the south, it occasionally occurs north of the Yangtze Valley.

The crop-growing season varies in length from the entire year in the south, to 8 or 9 months in the Yangtze Valley, 7 months in the more northerly Hwang Ho Valley, 6 months in Hopeh, 5 in Manchuria, and only 4 in Tibet with its two-mile or more elevation.

Population.—There has never been a census of the entire population of China and consequently any figure given for the total number of inhabitants can be only an estimate. According to the Directorate of Statistics of the national government of China, the population of China in 1947 was 461,406,285, distributed as shown in Table 1. (In mid-1948, the official estimate was 463,493,418.) Populations of the principal cities were given as follows: Nanking, 1,037,656; Shanghai, 3,853,511; Peking, 1,602,234; Tientsin, 1,679,210; Tsingtao, 752,800; Chungking, 1,000,101; Mukden (Shenyang), 1,175,620; Hankow, 749,952; Canton, 1,276,429; Sian, 523,183; Pinkiang (Harbin), 760,000; Talien (Dairen), 543,690. About 26,000,000 non-Chinese-speaking people, most of whom live in the northwestern, southwestern, and northeastern provinces, are included in the population figures. At the end of 1947, an official estimate gave the number of overseas Chinese as 8,721,204. Of these, 8,379,720 were in various countries of Asia, 53,759 in Europe, 63,835 in Oceania, 14,851 in Africa, and 209,039 in North and South America (77,504 in the United States¹).

Fauna and Flora.—The fauna of China is widespread and varied, though a large proportion of the larger mammals are found in the north and west. There are several species of deer among which the roe, musk deer, and sika have been hunted in the past by foreigners in the mountains of northern Shansi and Mongolia. Wapiti and antelope, as well as the wild sheep, wild ass, and wild boar, also excite the Western sportsman's enthusiasm. North China and Manchuria are the home of many fur-bearing animals that have commercial importance. Among these are the badger, sable, marten, mink, weasel,

¹ According to the 1940 census, which listed 40,262 as native and 37,242 as foreign born

wolverine, otter, fox, several kinds of squirrels, marmot (thought to be the means by which pneumonic plague is transferred), and the raccoon dog, an animal resembling but slightly smaller than the American raccoon, which produces a fur called on the market Chinese coon. It is said that in normal times more fox skins are shipped from the port of Tientsin than from any other port in the world. Bears in China include the Tibetan black bear, the Manchurian black bear and grizzly, and the giant panda, found in Kansu, Tibet, and Szechwan, specimens of which have been brought out of China for zoos in the United States. Other carnivora, besides those already mentioned, are the tiger, manul, leopard, and the Chinese wolf. There are several kinds of monkeys.

Fully one half of all the species of mammals in China are rodents. Many varieties of rats, mice, chipmunks, gophers, squirrels, and hares abound. Insectivora are few in north China on account of its dry climate, but central and west China are the habitat of many moles, hedgehogs, and shrews. Amphibia are represented by several species of toads and frogs, some like those of Europe. There are many species of snakes in China, most of them of nonpoisonous varieties. Among the venomous species is the cobra, which differs slightly from the Indian variety. Turtles and tortoises are well represented, the latter being a sacred animal and an emblem of longevity. The Chinese alligator, smaller than its congener in the Western Hemisphere, rarely reaches more than six feet in length.

An important item in the diet of many Chinese is fish. Shad, perch, bass, sturgeon, a variety called perch pike, and loach, found in mountain streams, are said to be the most edible. However, many other kinds are also used for food.

China is particularly rich in birds. Of the birds of prey several kinds of owls, hawks, falcons, and eagles abound. The vulture, buzzard, and carrion crow represent the scavengers. There are several varieties of pheasants, some of them very beautiful birds, though all characteristically have white collars. Other game birds are the partridge, quail, plover, and woodcock. Water birds are particularly numerous; the most interesting, at least to Westerners, is the cormorant, which has been domesticated and trained to catch fish. Attached to a long string and with a ring around its neck, the bird dives in at the sight of a fish and with its prey is hauled up by the fisherman. Other water birds are ducks, pelicans, geese, herons, bitterns, cranes, storks, gulls, terns, and ibis. Representative of the songbirds are the thrush, bulbul, and lark. There are several species of doves and pigeons, and woodpeckers, swifts, nightjars, ravens, starling, finches, sparrows, swallows, martins, wrens, orioles, buntings, and bramblings are all represented.

Of the domesticated animals of China, only three are important as productive: pigs, sheep, and goats. Cattle are raised, but in very small numbers, chiefly for the consumption of Moslems or resident foreigners. Draft animals in north China include camels, donkeys, mules, oxen, and to a lesser extent, horses. In the far north, however, the Mongolian horse, bred in rather large numbers, is necessary in the activities of the Mongols. In the mountains of the southwest Chinese ponies, little larger than the Shetland, are raised for difficult transportation work. The

water buffalo is used in south China for plowing.

China has the largest flora of all the temperate zone countries. It is the original home of many plants, some of which North America received by way of Europe, such as the peach, apricot, hemp, certain kinds of ginger and rhubarb, tea, sarsaparilla, and many citrus fruits. Trees cut for timber grow chiefly in Manchuria, the southeast coast and the southwestern provinces. These are pine, spruce, larch, elm, birch, oak, and fir. Other trees, less important for the lumbering industry, are the cedar, poplar, willow, alder, ash, maple, gingko, and in the warm south, the rosewood acacia, banyan, and sago palm. All kinds of melons are grown and fruit trees include the peach, apricot, several varieties of cherry, pear, occasionally the plum and in the subtropics of the south the orange, lime, loquat, pomelo, pomegranate, mango, persimmon, fig, olive, litchi, and even the banana. Apples grow in China, though they are large and white or small and red like crab apples, and not the delicious fruit of the northern United States. Among nut trees the walnut, chestnut, and pistachio are common.

Food plants consist largely of cereals and vegetables, though the use of various soybean products is becoming widespread. In north China wheat, sorghum, barley, millet, corn and a little rye and oats are grown. Rice is the staple in the south. Vegetables are varied and range from the potatoes, sweet potatoes, eggplant, yams, turnips, carrots, onions, cucumbers, beans and peas, all of which are common in the United States, to several varieties of greens and cabbage and lotus bulbs. Fiber plants include ramie, known commercially as China grass, and cotton, both of which are exported, and flax, hemp, and some jute. Large quantities of tea grow in the lower Yangtze Valley and Szechwan. Much of it is exported, some being made into bricks for sale to the Mongols. Tobacco, sugarcane, and the mulberry, on the leaves of which silkworms feed, are all grown commercially. Perhaps of all plants in China the bamboo has the most varied uses; from it are made many articles which range from mats and baskets to tobacco pipes, ladders, musical instruments, and chopsticks, while the sprouts are used for food. Important oil plants are sesame, rape, peanuts, also used as a food, and the seeds of the tung oil tree, used in the making of paint and varnish. Cassia, ginseng, and ma-huang, from which ephedrine is extracted, are medicinal plants.

Among the flowering plants and shrubs are the rose in varieties, and the lilac, peony, orchid, oleander, chrysanthemum, morning glory, iris, lily, honeysuckle, wisteria, water hyacinth, lotus, poppy, one variety of which has been important as the source of opium, gardenia, camellia, and many varieties of azaleas.

Geology.—Underlying all China are the Paleozoic crystalline formations which are the foundation of the continent. They reach the surface in only a few places, among which are Tibet, where loess deposits, sand, gravel, or Mesozoic deposits cover the ancient rocks; the eastern coast provinces of Kwangtung, Fukien, Chekiang, and Shantung with their bleak mountains of granite; and Inner Mongolia, where the ancient formations are partly covered by Tertiary deposits. The secondary deposits of limestones, sandstones, and shales were laid down between the ancient land masses as continental and par-

ticularly marine sediments from the beginning of the Paleozoic through the Jurassic. Northeast China was uplifted by the Carboniferous period, but the rest of China Proper was subject to recurring marine incursions until the Jurassic period. Most of the mountains north of the Yangtze are apparently the result of gentle folding at the end of the Jurassic or the beginning of the Cretaceous and intense folding and thrusting at the end of the Cretaceous. Perhaps the mountains south of the Yangtze were a result of the same action, though the geology is too imperfectly known to say definitely. In the west the Altai Mountains were formed by faulting while the Tien Shan, Kunlun, and Himalaya ranges were the result of folding. During the Carboniferous and Jurassic periods important coal deposits were laid down. In the north an important surface feature is the layer of yellow earth called loess, believed to have been carried in by the winds from Mongolia and Central Asia beginning with the Eocene period. The large alluvial deltas built up by China's great rivers tend to offset the sinking coast, particularly apparent in the southwest, where fiords extend into the land and many islands lie offshore.

Minerals.—From the time of the first travelers from Europe the belief has been widespread that China has a tremendous mineral wealth. Geological surveys, conducted since the establishment of the republic, have revealed that no such reserves exist, with the possible exception of coal. There are three areas in China in which much of the mineral wealth lies: the mountains between the Hwang Ho and Yangtze, the hills south of the Yangtze, and the southwestern provinces. Until the war with Japan forced the government to move west in 1938, adequate surveys of the southwest had not been made, but they were carried on in the course of the war.

According to the *7th Special Report* (1945), of the National Geological Survey of China, China has a coal reserve of 265,314,000,000 metric tons, of which 98.95 per cent is based on actual geological survey. Three fourths of this is in the northwestern provinces of Shansi (47.92 per cent) and Shensi (27.12 per cent). All provinces have some coal, but the remaining 25 per cent is largely in the north and northwest. Because the large deposits are distant from the coast, from metal deposits, and from large centers of population, production areas bear little relation to the location of reserves. Of the 18,158,000 metric tons produced in 1946, the two coastal provinces of Liaoning and Hopeh produced more than one third, while Shansi and Shensi produced less than 9 per cent of the total output. Other provinces which produced more than 1,000,000 metric tons of coal in 1946 were Szechwan (1,800,000), Honan (1,000,000), and Jehol (1,500,000). Formosa, in 1950 the only considerable piece of territory in the hands of the Nationalists, produced another 1,000,000 metric tons. Total production in 1948 was estimated at 13,800,000 metric tons.

China has a total known iron ore reserve of 2,150,511,000 metric tons, of which 91.91 per cent is based on actual geological survey. The province richest in iron, though much of it is low-grade ore, is Liaoning, with 64.38 per cent. Hopeh (6.63 per cent), Fukien (4.29 per cent), and Chahar (4.15 per cent) follow next in order. The quality of Chinese iron ore is generally poor.

About 32 per cent of the total iron reserve has a metallic content of more than 50 per cent (ore of this type is found largely in Chahar, Fukien, Kweichow, Sikang, Hupeh, and Shansi), while 59 per cent of the total reserve has a metallic content of below 50 per cent (all of Liaoning's ore is of this type). The quality of the remaining 9 per cent is as yet unknown. Before and during the Sino-Japanese War, the Japanese operated all the iron mines in China except those in the southwest. Production after the war was slight. In 1946 and 1947 the output of pig iron for all of China was but 31,000 and 35,733 metric tons, respectively.

Petroleum is conspicuous by its absence over most of China, and geological factors make the discovery of a major field unlikely, although there are possibilities in the far west—in Kansu, Sikang, and the eastern and northern rims of the Tibetan plateau. The National Geological Survey estimated the total reserve of petroleum at 206,666,000 metric tons, distributed as follows: Sinkiang (120,000,000), Kansu (60,000,000), Shensi (20,000,000), Chinghai (5,000,000), and Szechwan (1,000,000). There are oil shale deposits in Jehol, Chahar, Shansi, and Shensi, but the biggest is in Liaoning. This shale contains only 5 per cent oil, and its economic value is due to the fact that it overlies the coal seams which must be stripped for mining. Consequently the cost of producing the oil is nominal. In 1942 the Japanese produced 700,000 metric tons of oil from the shale deposit at Fushun, Liaoning.

The production of gasoline and kerosine from natural oil in China mounted steadily after 1939. In 1947 it amounted to 7,800,111 gallons and 4,002,258 gallons, respectively.

Resources in copper are poor, although this metal has been used by the Chinese for various purposes for over three millenniums. The two leading centers of production are in northern Yunnan (about 500 metric tons a year) and southwestern Szechwan (about 100 metric tons a year). Another 347 metric tons (1946) are mined elsewhere, copper ores existing in almost every province, though of poor grade and of limited amount. According to the National Geological Survey, the total copper reserve in China is 967,370 metric tons.

In contrast, the country's resources in tungsten and antimony are superlative. The main reserves, located in the southern provinces of Kiangsi, Hunan, Kwangtung, and Kwangsi, are 2,035,000 and 3,802,870 metric tons, respectively. Production of tungsten in 1948 was estimated at 9,327 metric tons; of antimony, 3,300 metric tons—much less than before the war.

Resources in other metals range from moderate to fair. Of tin there is a reserve of some 650,000 metric tons, nearly half of which is located in Yunnan. Production of tin ore in 1948 amounted to 4,900 metric tons. Reserves of bauxite and alunite amount to 150,000,000 and 198,991,000 metric tons, respectively. There are also limited deposits of manganese, lead, zinc, mercury, sulphur, and silver, and somewhat more plentiful resources in gold and aluminum. Production of lead, zinc, and gold in 1947 amounted, respectively, to 771 metric tons, 320 metric tons, and 107,030 ounces. All of these figures represented a marked falling off from production a decade before.

Porcelain clay, or kaolin, which the Chinese for centuries have worked so skillfully that the

name China has been attached to the ware, remains an important resource (see section on *Ceramics*). Jade, always highly prized by the Chinese, now comes from Sikang and Sinkiang, though once it may have been found in certain riverbeds of China Proper. Yunnan produces emeralds, amber, agates, rubies, and sapphires.

Agriculture.—China has always been an agricultural country, and even now three fourths of the population are farmers. In the days of the empire the importance of farmers was recognized by considering them as the second class of subjects, ranking only below the scholars. Furthermore, the emperor himself gave dignity to their work by going to the Temple of Agriculture each year at the beginning of the planting season to plow a furrow and sow some seed; his representatives in the provinces conducted the same ceremony. According to the *China Handbook* (1937-1945), the cultivated acreage in China (exclusive of Tibet and Formosa) is as shown in Table 2.

south and central China. This makes it ~~un~~ and in some cases impossible to use farm animals. The large population provides human laborers for the most menial tasks. As many crops are raised as the climate will permit; in the south usually three a year are grown, but only one summer crop will mature in the north. Constant use of the land necessitates continual addition of fertilizers, the principal ones being ashes, beancake, mud from the bottom of canals, and night soil. The yields per acre are, in general, higher than the world average; nevertheless, China cannot produce enough to feed her population. Every year wheat, wheat flour, rice, and sugar (also tobacco and cigarettes) are imported.

Agriculturally China is divided into two parts by the Chinling Shan. To the north wheat, sorghum, and millet are the staple crops. They are grown on dry fields, though irrigation is practiced in Ningsia and Suiyuan. Actually in much of this region agriculture is somewhat pre-

Table 2—LAND CULTIVATION IN CHINA

² 1 shih mow = $\frac{1}{3}$ of an acre.

Because of the pressure of the large population in China, almost all cultivable land is now tilled; even hillsides where the soil is not too thin are terraced and planted. This is a characteristic feature of all the Szechwan Basin, where the terraces often extend to the very hilltops; except in the deltas nearly all rice paddies are terraced though they do not reach far up the hillsides in south China because the soil is thin. There are few meadows, orchards, and wood lots, and even animals, except chickens and pigs, which forage for themselves, are not raised in any numbers for food because the cereal crops are needed for human consumption. Even so, a crop failure may cause widespread suffering, partly because adequate means of transportation are not available to bring in food from more productive areas. Chinese farming has been likened to gardening because it is highly intensive. The farms are small (the average for all China is 3.3 acres), but even then they are likely to be cut up into nonadjacent plots, especially in

carious because of a light rainfall, but the moisture-retaining quality of the loess tends to ameliorate conditions slightly. In Manchuria and the provinces along the northern border wheat is planted in the spring, since only one crop can be raised during the year. In a belt of provinces lying across China west of Hopeh and Shantung wheat is planted in the winter so that a second crop may be raised in the summer. Other important crops in this area are barley, oats, flax, peas, soybeans (particularly in Manchuria), hemp, cotton, tobacco, peanuts, corn, sesame, and rape. In addition, all kinds of garden vegetables including sweet and Irish potatoes, carrots, onions, cabbages, string beans, and peas are grown. Melons, pears, and persimmons grow on the North China Plain, and Kansu produces excellent apricots and peaches. Shansi, Shantung, and the Liaotung Peninsula produce some silk but the worms are fed on oak rather than mulberry leaves. In general, there is not so much hand labor as among the farmers of south

China, and mules, donkeys, and oxen are used for plowing. Only in Manchuria is farming done on a large scale with modern machinery.

In the south, rice is the staple crop, though winter wheat is grown in southern Szechwan, Hupeh, southern Kiangsu, and northern Chekiang. In other provinces two crops of rice are grown. The water buffalo, the principal farm animal, is used for plowing the paddy fields, but rice culture necessitates a tremendous amount of hand labor. Tea is grown in the hills which form the Fukien-Kiangsi border, in western Chekiang, in northwestern Kiangsi, and in Szechwan. At the turn of the century China supplied more than 40 per cent of the world's tea, but by 1925 only a little more than 10 per cent came from that country as a result of poorer quality and the lack of interest and money on the part of the farmers in improving the grade. Growing mulberry leaves for silkworms is important in the lower Yangtze Valley, in Hupeh, Szechwan, and Kwangtung. Other important crops in south China are beans, tung seeds, bamboo, sugarcane, tobacco, rape, cotton (in the Yangtze Valley) and vegetables of all kinds. In the south and along the southeast coast citrus fruits grow in abundance. Kwangtung and Kwangsi produce litchis, bananas, ginger, and 65 per cent of the world's cassia. On the tableland of Yunnan and Kweichow grow excellent peaches, pears, apricots, persimmons, walnuts, and chestnuts.

Before the Sino-Japanese War the lot of the farmer was a hard one. From a small plot, cultivated almost to the economic limit, he secured enough for only the bare necessities of life. He himself had no capital for improvement, and at his death the land passed in even smaller plots to his sons. To combat this tendency the government set up a long range agricultural policy which includes scientific farming, large-scale farm management, industrialization of rural districts, commercialization of farm products, and a better rural system. Although putting the policy into operation has been retarded by the war, the government has, nevertheless, made a beginning. Irrigation projects completed up to the end of 1947 should bring water to a total of 7,589,494 shih mow of land, over half of which is located in the northwest. Further, the National Bureau of Agricultural Research established several regional substations for crop improvement. These included, in north China, nine field stations for wheat, rice, cotton, sweet potatoes, and other crops; in the southwest, three field stations for tung oil trees, tea, and Irish potatoes; in Hunan, Kwangsi, and Shensi, three field stations to co-operate with the provincial agricultural improvement bureaus with respect to rice, sugarcane, wheat, cotton, and other crops; and in Fukien, a tea experimental station. Extension work for the purpose of distributing improved seed and stock has been established in the various provinces.

In 1947, in the whole of China, 42 per cent of the farmers owned their land, 25 per cent were part owners, and 33 per cent were tenants.

Industry.—Before the Sino-Japanese War almost all of Chinese industry, having developed as private enterprise, was concentrated in cities along the coast, or on the Yangtze River. After the outbreak of war in 1937, some 639 factories and plants moved to the west. These included the following industries: iron and steel, chemicals, textiles, machine making, electrical, and food. After the trek to the west, the Chinese govern-

ment took an active interest in industrial development and by 1942 there were 98 state-owned industrial plants in free China. At the same time private industry expanded in the west so that by May 1942, free China had 1,915 privately owned factories. A third phase of China's wartime industry was the development of co-operatives, of which there were 1,590 by mid-1942. After the war, activities were resumed in large measure in cities formerly occupied by the Japanese. In December 1947, there were registered with the government 15,000 factories with a total labor force of 859,485 workers and a total capacity of 4,129,015 horsepower. In terms of capitalization or labor force, the textile industry ranks first, with 4,543,429 spindles in October 1948.

Transportation.—China's commerce is carried on by means of shipping lines, roads, railroads, and airlines. From ancient times the waterways have been important in the history of communication, the two main river systems being the Hwang Ho in the north and the Yangtze in the south. The rivers flow in a west to east direction and the country is intersected by innumerable canals connecting the natural waterways. The greatest of these is the 1,000-mile-long Grand Canal, running now between Hangchow and Peking, begun about the 5th century B.C. It was frequently extended, notably between 600 and 1300 A.D. In recent times, however, the canal has been allowed to fall into disrepair. Chinese shipping has for some time been handicapped by the inland navigation rights enjoyed by the treaty powers so that the total tonnage of Chinese steamships was only a little more than half a million tons before the war, but by immediate action after the outbreak of hostilities in 1937, the Chinese government was able to save all but an estimated 29 ships (48,359 tons) from the Japanese by ordering all ships to proceed up the Yangtze or to Hong Kong. Since 1937 emphasis has been placed on the development of inland navigation. Ships have been built and new navigation lines have been opened on hitherto uncharted inland rivers. The National Conservancy Commission, established Sept. 1, 1941, surveyed 6,875 miles of rivers and started work on 2,360 miles to make them navigable.

There are two principal shipping companies of China. The more important, the Ming Sung Industrial Company, established in 1924, limited its activities to the Yangtze and Szechwan rivers. At the close of 1942 this company with a capitalization of \$7,000,000 owned a fleet of 87 steamers totaling more than 21,000 tons. The China Merchants' Steam Navigation Company, organized in 1872 as a joint government and commercial enterprise, confined its shipping to coastal ports and Yangtze ports below Ichang before the war. After the fall of Hankow in 1938 its business virtually ceased except for a few small boats in Szechwan waters. The Ministry of Communications purchased the company in 1932. In 1942, plans were laid to develop shipping on the rivers of Szechwan and Hunan. As of June 1947, China had 3,348 steamships totaling 883,483 tons. Of these, 251 steamships with a total tonnage of 143,566 belonged to public institutions, and 2,702 steamships, totaling 481,832 tons, belonged to private companies.

Roads.—Before the republic all but a few of the roads were mere tracks or paths. In 1912 the first highway for motor traffic was con-

structed in Hunan, and five years later the Kalgan-Urga Motor Company built a highway between Kalgan and Ulan Bator (Urga) and opened the first commercial highway transportation business in China. From that time until 1932, when the Bureau of Roads was set up as a department of the newly established National Economic Council, road building was left to provincial government. Between 1932 and 1937 roadbuilding was pushed so that by July 1937 road networks began to take shape in all the provinces, making a total of 71,894 miles of highways in China, 24,990 of which were surfaced roads.

When the war with Japan broke out in 1937, roads became more important than ever before; accordingly the government set up the Bureau of Highways under the Ministry of Communications in January 1938 to oversee construction. By this time the Chinese government was interested particularly in communications in western China, so that motor roads were grouped into three sections: the southwest network with Kweiyang as a center, the northwest network with Lanchow as a center, and the network about Chengtu connecting the first two. Within two and one-half years after the beginning of the war, 2,003 miles of new roads were built and 11,075 miles of roads, hitherto unsuited for motor traffic or fallen into disrepair, were rebuilt. Standards were fixed by the national government: trunk highways were to be at least 39 feet wide; secondary lines, 29 feet wide. In road construction emphasis was laid on international highways and arteries linking provinces in the interior. Besides the Burma Road, there was the important 1,662-mile highway from Lanchow by way of Tihwa to Ayaguz, where it connected with the Turkestan-Siberian Railway. Two other international roads into Indochina, one from Yunnan and another from Kwangsi, finished in 1940, were rendered useless by the Japanese occupation of Indochina. Another important international highway, the Yunnan-Assam road, was opened in January 1945 after the Japanese had been cleared out of the area by the Chinese.

Between August 1939 and the end of 1940 the Chungking government issued 16,429 licenses to nonmilitary vehicles. (Compare this figure with 43,854 vehicles in China in 1932.) Because of the shortage of gasoline, almost all the vehicles, except those in the northwest where there are oil wells, had converted to gasoline substitutes, the commonest being charcoal.

In Chungking on Jan. 1, 1940 the China Transport Corporation was formed by the amalgamation of two smaller companies. In 1944 the company maintained freight and passenger lines in Szechwan, Yunnan, Kweichow, and Kwangsi provinces. One route from Chungking went through Kweiyang to connect at Hochih with the railway to Kweilin; another from Chungking connected at Chutsing (Kutsing) with the railway to Kunming and southern Yunnan. In June 1941 the company had 338 passenger buses, but a year later only about 100 could be used for regular service.

Because irreplaceable vehicles were slowly breaking down and supplies of gasoline were meager, the Chinese government established stage transportation. Various means were used: carts pulled by men or animals; junks, steamers, human carriers, or pack animals including horses, mules, and camels. Up to 1944 six national lines

had been established: Szechwan-Kweichow, Szechwan-Shensi, Shensi-Kansu, Kansu-Sinkiang, Szechwan-Yunnan, and Szechwan-Hunan-Hupeh. There were also almost 19,000 miles of branch lines. In 1941, 1,284,170 tons of freight were transported over the six national lines. As of June 1948, China had 81,966 miles of roads. The total number of licenses issued by the government to nonmilitary vehicles was about 75,000.

Railroads.—Chinese railway history dates back to 1876, when British and American merchants of Shanghai built the 10-mile Shanghai-Woosung line only to have it taken over and destroyed by the Chinese government the following year after the accidental death of a Chinese. That same year Li Hung-chang, viceroy of Chihli, granted permission for the construction of a tramway from the Tongshan-Kaiping coal mines to deep water at Taku. Although the permission was for animals as power, the English engineer Kinder planned for a railway from the beginning and built an engine from material locally available. This short line was extended to Tientsin by 1888 and shortly thereafter in the opposite direction to Shanhaikwan (now Linyu). After the defeat by Japan in 1895, the Chinese government wished to build more railroads, and since capital was not available in China, foreign loans were obtained. European countries were eager to lend China money for construction in their particular spheres of influence, for in some instances China gave a 99-year lease and full control of the railway to the lender. Under this arrangement the Russians built the Chinese Eastern Railway across Manchuria, 1897-1903; the Germans built the Kiaohsien-Tsinan line, 1899-1904; and the French extended the line from Indochina to Kunming, 1904-1910. Over the Belgian-financed Peking-Hankow line, built 1898-1905, the Chinese retained control. About the same time railways were built from Shanghai to Ninghsien and to Nanking, financed by the British. By the end of 1915, China had about 5,400 miles of railways of which all but 570 were north of the Yangtze (including Manchuria) with Peking as a center. Of the 570 miles in southern China branches in two directions from Canton accounted for 119 miles and the Nanking-Shanghai-Ninghsien railway, for 371 miles. By 1931, when the Japanese seized Manchuria, China had approximately 9,300 miles of railways of which about 40 per cent lay in the lost territory. Sections constructed between 1915 and 1931 include: (1) the extension of the Lunghai railway from Tungshan (Suchow) to Tunghai (Haichow) on the coast and to Sian in the west, (2) from Tungkwan on the Lunghai north to Yangku (Taiyuan), (3) from Yangku to Chengting on the Peking-Hankow line, (4) Hankow-Changsha, (5) Nanchang-Kiukiang, and (6) a section north of Canton on the Canton-Hankow line.

In 1936, Chiang Kai-shek drafted a five-year plan for railway construction. The completion of the Canton-Hankow, Sian-Paoki, Hengyang-Kweilin, Wuhsien (Soochow)-Kashing, and the Chekiang-Kiangsi (Hangchow to Lishui on the Canton-Hankow) lines before the evacuation of eastern China facilitated the trek to the west. By the end of 1942 only 10 per cent of the old railways remained in free China, but 750 miles of new railways had been built and 380 miles were under construction in the west. Completed since the outbreak of the war are the Hsienyang-Tungkwan branch of the Lunghai railway, the Kwei-

lin-Liuchow (Maping) section of the Hunan-Kwangsi line, the Liuchow-Hochih branch of the Kweichow-Kwangsi line, and the short Kunming-Chutsing (Kutsing) section of the Ipin-Kunming railway. In 1944 the Kweiyang-Hochih was under construction, but on the following lines construction had been suspended: Chengtu-Chungking, Liuchow-Chennankwan (on the Indochina border), Kunming-Burma, and the Chutsing-Ipin. One more line, the Paoki-Tienschui-Chengtu, had been partly surveyed.

In 1944 only 1,829 miles of railways were in operation in free China, but they were an important means of communication. It should be remembered that the Chinese armies completely destroyed several sections of the Canton-Hankow, Lunghai, and Chekiang-Kiangsi lines by removing the rails and dynamiting the roadbed as a measure of defense. Since the end of the war, however, in spite of civil disturbances many lines were repaired and resumed a measure of service. At the end of 1948 total trackage was 18,757 miles, of which (September 1948) 8,120 miles were in operation.

Airways.—Commercial aviation in China began in 1929 with the organization of the China National Aviation Corporation, a joint Sino-American enterprise. Two years later the Eurasia Aviation Corporation, a Sino-German firm, was organized primarily for the purpose of carrying mail between China and Europe. A third company, the Southwestern Aviation Corporation, existed from 1932 until it was dissolved in 1938; a purely Chinese company, it was subsidized by the provincial governments of Kwangtung and Kwangsi over whose territories its lines passed. Between October 1929, when the C.N.A.C. made its first flight, and July 1937, the two important aviation companies had together built up 8,591 miles of air routes with 30 airplanes of German and American makes operating on the lines. After five years of war, of these original lines, only 584 miles remained in free China, but 5,779 miles of new airlines had been opened, most of them in west China.

The C.N.A.C. before July 1937 operated lines from Shanghai to Chengtu, to Peking, and to Hong Kong through Canton, and a Chungking-Kunming line. As the Japanese penetrated China, all the lines except the last named had to be given up, but fortunately the company lost few planes and was therefore able to open new lines in west China. The following new routes were opened: Hankow-Changsha, 1937; Chungking-Hong Kong, 1937; Chungking-Loshan (Kiating), 1938; Chungking-Hanoi, 1939; Chungking-Rangoon, 1939; and Hong Kong-Namyung, 1940. At Hong Kong, C.N.A.C. had connected with Pan American Airways' transpacific service to the United States and the British Imperial Airways' services to Europe and Australia. With the extension to Hanoi, connection was made with Air France and at Rangoon there was established another connection with British Imperial Airways as well as K.L.M. (Royal Dutch Airlines). Japanese military action eventually made all these lines impossible, save the one from Chungking to Loshan, thereby cutting off all the connections which the company had with foreign airlines. Only 10 days after Pearl Harbor, however, the Chungking-Calcutta route was opened, the last important road linking free China with the outside world. In 1942 the C.N.A.C. added a regular service from Chungking to Lanchow. In

1936, the biggest year of business before the war, its planes flew 1,543,217 miles and carried 15,748 passengers, 190,703 pounds of mail, and 103,484 pounds of freight. After the Japanese attack, the amount of business sharply decreased until new lines could be established in the west. A second blow came when the Japanese took Hong Kong.

The Eurasia Aviation Corporation, from its establishment in 1931 until 1941, when the Chinese government broke relations with Germany, used only German planes and brought in from Germany the air and ground crews and advisers. After 1941 it became a Chinese company. Before 1937 the company established the following lines: Shanghai-Lanchow, Peking-Loyang, Lanchow-Paotow, Peking-Canton, and Sian-Chengtu-Kunming. After war broke out Eurasia moved from Shanghai to Kunming and continued flying in west China, to Hanoi and to Hong Kong. The company was badly hit when the Japanese took Hong Kong in December 1941, for only one plane was saved. One year later, Eurasia flew its four routes with that single plane. Within six months after the close of the war in August 1945, the Chinese government announced plans for re-establishing the airways and rebuilding the roads and railroads. As of September 1948, the country had 97 planes for civil aviation with air routes measuring a total of 55,352 miles.

Government.—Government emerged slowly in China, as elsewhere in the Old World, out of a community and tribal background until by approximately the beginning of the second millennium before our era a single ruling family is said to have dominated an area in the Hwang Ho valley. We learn from the excavation of a single city, which was the seat of government from about 1300 to 1050 B.C., that the next ruling house of Shang had a considerable court which required several government buildings, palaces, temples, and mausoleums. At the top was a king, with whom was associated one or more consorts. He led in matters of war and of religious observance. It was important for him both to defend his area from attack and to conform with nature so that his people might be blessed both with peace and abundance. Besides military and civil officials there were priests who helped him by divining the future, determining the calendar, and supervising sacrifices at proper times.

Toward the end of the 11th century B.C. a new ruling house (the Chou), which conquered the Shang, expanded the area of rule to include both the major river valleys. Its method of government differed from what preceded in that the country was divided into fiefs officered by the king's near of kin, military chiefs, and leading allies. These were ruled with increasing independence throughout the next few centuries, until after 771 the lords paid little more than lip service to their king. Another point of difference was the introduction of the institution of eunuchs, who from servitors in the palace frequently developed into influential advisers and powerful officers of state.

The last king of Chou disappeared in 256 B.C. After a period of anarchy, one of the states contending for mastery (the Ch'in) beat all others into submission and for the first time set up an empire. Feudalism was abolished and the country was divided at first into 36 areas, each with its military governor, civil administrator, and supervising official, all responsible to the em-

peror. Nobility was continued, but instead of being hereditary it was based on services and gifts to the state. Although the house of Ch'in survived only a few years, it created a method of government that was to last for over two millenniums. The thinkers of this age believed in centralization, with the head a kind of patriarch, his officials subordinate parents, and the people children. The ancient system of the family was thus the pattern. Political institutions were not infallible—in fact Mencius defended the people's right to rebel—but the family was (to be unfilial was the supreme sin). Hence during the next empire, that of Han, the system of thought called Confucianism, which supported monarchy of this type, became the favored one of the bureaucracy, and all those seeking appointment studied the Confucian canon.

While laws were made, a sense of justice was considered more important (as in a family); so the empire was actually a government of men rather than one of laws. China's political philosophy cannot better be summed up than in the words of a 19th century British author:²

"(1) The nation must be governed by moral agency in preference to physical force.

(2) The services of the wisest and ablest men in the nation are indispensable to its good government.

(3) The people have the right to depose a sovereign who, either from active wickedness or vicious indolence, gives cause to oppressive and tyrannical rule."

In 1911-1912 this ancient and elaborately developed system was set aside in favor of one largely derived from the West: a republic. The main surviving instrument was that of the hsien or county magistrate, often called the father and mother of his people. After some 15 years of trial and error a new government was formed, in 1926-1928, responsible to a single party, the Kuomintang. While theoretically still existing in 1950, this government had been driven by military action out of China Proper and was limited mainly to the island of Formosa. It was succeeded on the mainland (officially since Oct. 1, 1949) by the People's Republic of China. The leaders of the new group consciously drew upon the writings of Karl Marx for inspiration and patterned some of their techniques of government after those worked out by their powerful neighbor, the USSR.

Representing the people in the new republic is the People's Political Consultative Council or Conference, composed of delegates of all parties, people's organizations, the army of "liberation," and even overseas Chinese. This body is to meet once every three years. Between plenary sessions of the council a National Committee performs all necessary functions. The committee includes a chairman, 6 vice chairmen, and a Central People's Government Council of 56 members, one of whom serves as secretary general. In addition, there is a Military Council, with a chairman and 5 vice chairmen, one of whom is commander in chief of the army, a procurator, a supreme court, and a State Administrative Council. Chairman of the last named, also called premier, is assisted by 4 vice chairmen, 4 commissions (political and legal, finance and economics, culture and education, and control), and 30

ministries ranging from foreign affairs to agriculture, labor, and the inspectorate general of customs. Besides these ministries maintained at the capital, Peking, there are regional military and political committees, appointed by the state administrative council, governing five of the six major regions into which China has been divided: northeast, east, central and south, northwest, and southwest. The five northern provinces close to Peking, which form the sixth region, are administered by the central government.

Education.—Education of the brightest boys in the body politic has long been a concern of the Chinese people. Education of girls has been left to the home until recent years. Adult education is a novelty of the last generation.

Before and after the time of Confucius tutors found employment in the chief centers of population in the Hwang Ho valley, and—if famous—attracted to their academies a considerable following from the youth of well-to-do families. These youth were initiated into the mysteries of rhetoric, history, poetry and prose, ethics, thought, military science, astronomy and mathematics, and such varied fields as divination, music, medicine, law, and existing trades. Different schools of thought flourished in different centers, and brilliant students moved from one center to another. Out of these schools came a considerable literature, much of it produced by the disciples of various masters, not necessarily by the masters themselves.

By the 2d century B.C. there came into being a few higher schools supported by the state, which trained young men in the doctrines upheld by the ruling house and sent them out to become members of the bureaucracy both in the capital and throughout the empire. These schools multiplied and increased their enrollment greatly in the next three centuries. The leading institute at the capital, for example, started with 50 students in 125 B.C.; by the 2d century A.D. it is said to have had 30,000. During the 400 years of disunion which followed, state education suffered, although a number of men became highly educated through private instruction. In this the Buddhist monasteries began to play a conspicuous part. When China was reunited under the T'ang, the following argument was used against them: "The priests arrogate to themselves," said one courtier in 624, "the right to educate the people, withdrawing from the Emperor this right which belongs properly to him, thus diminishing his authority and prestige."

At the beginning of the 7th century there was a resumption of education under imperial auspices stimulated by the system of state examinations through which an aspirant for office had to pass. The two capitals of Sian and Loyang became important centers of learning and many students from all over the nearby Asiatic world flocked there. It has been reported that the National Academy alone boasted 3,260 students in 631 and 8,000 in the 9th century. Besides this academy there were other colleges for the study of various subjects including government, law, calligraphy, and mathematics. Young boys, as in the 1st century B.C., were taught through exercise books of from 1,000 to 1,400 characters which introduced the Confucian ideas of the time in rhymed verse. One closes with the following minatory couplet:

"O children embarking on your studies
Be quick to learn and slow to forget."

Under the Sung an attempt was made, with scant success, to promote more practical training for men seeking appointments in civil service, and public school education was extended throughout the empire. These government schools were partly supported by income from land set apart for the purpose. Primary education was left, as before, largely to private initiative.

This situation obtained without fundamental change until the 19th century, when the influence of Christian missionaries, the example of Japan, and reports from Chinese who had studied in Europe and the United States made themselves felt. Beginning with 1862, when a school was established in Peking for the training of diplomatic personnel, both public and private institutions of a modern type have grown up in all parts of China, particularly on the coast and in the valley of the Yangtze River. A significant step was taken by the Manchu government in 1905, when the time-honored but outworn system of examinations for civil appointment was abolished. By the time of the outbreak of war in 1937 the Ministry of Education reported 294,141 primary schools and kindergartens with 620,693 teachers and 16,629,644 students; 3,264 secondary schools with 26,510 teachers and 571,820 pupils; 108 colleges and universities with 7,560 officers of instruction and 41,922 students. In addition, an uncounted number of people were undergoing short courses in adult education, mainly elementary language (reading and writing) and citizenship.

From 1937 China suffered almost unbearable losses in plant, books, and laboratory equipment, not to mention personnel. The property destruction alone was staggering. In spite of this an astonishing number of institutions transferred their bases to that part of China not occupied by Japanese soldiery, and tens of thousands of students and teachers migrated thither to carry on, in spite of meager facilities and equipment and in the face of swiftly spiraling inflation. It was reported that on Jan. 1, 1943 there were 25 more institutions of higher learning and some 16,000 more students enrolled than in 1937; and that between 1938 and 1943 over 46,000,000 illiterates learned to read simple texts. After 1946 almost all educational bodies returned to their original plants and restored them, in spite of serious deterioration, to some measure of usefulness. As of 1947, there were 290,617 primary schools, with 23,813,705 pupils; 5,073 secondary schools, with 1,566,392 students; and 207 institutions of higher education, with 148,844 students.

Although the country was convulsed in 1949 by civil war and the people were operating largely under an entirely new government, for the most part educational institutions did not suffer physical damage nor did the faculties lose many of their members. On the contrary, a number were enthusiastic supporters of their liberators and were engaged in rewriting textbooks in the political and social sciences. Many thousands of the older students were drawn into government service, but as many more were encouraged to remain at their desks and laboratories to qualify for the many technical and social requirements of the new government. Although in 1950 many changes in emphasis and in subject matter were doubtless in store for the present and next generations of students, meanwhile even church-supported schools, with modifications in curriculum and administration, were encouraged to continue.

Religion.—Religion among the Chinese people began with the first stirrings of communal life in the Hwang Ho valley. Recent finds in Neolithic and Early Bronze Age settlements indicate that they practiced scapulimancy, erected shrines, performed sacrifices, worshiped a variety of gods (including gods of the soil), and that the ruling class, at least, worshiped their ancestors. By the third quarter of the first millennium before our era religious practices and beliefs had been widely extended and formalized, and the greatest religious and moral leaders of the Chinese had appeared. These leaders included those in the *Ju* (Confucian) school: Confucius, Mencius, and Hsün-tzu; those in the school led by Mo Ti; and those in the (Taoist) school of Lao-tzu (Lao-tse) and Chuang-tzu. Of these the only group to set up anything resembling a church were the followers of Mo (who preached the doctrines of mutual love and pacifism); it died about the 1st century A.D. The other schools, however, expanded under governmental and popular support until by the same century and the next they were strongly entrenched and boasted an important literature. To preserve it this literature was frequently carved on stone tablets; in the 10th century and later it was printed and reprinted many times.

In the 1st century Buddhism (q.v.), carried by missionaries from India and nearby Buddhist lands, penetrated China and shortly made a profound impression not only on the hearts and minds of the people, but also on their art and architecture, science, literature, language, and even their indigenous religious institutions. By the 12th century Buddhism had been absorbed, missionaries ceased to come, and its influence generally declined. Confucianism and Taoism—both of which had drunk deep at the well of the Indian faith—superseded it (see CONFUCIUS; TAOISM). Other religious cults which have affected the Chinese are Zoroastrianism (6th to 9th centuries, q.v.); the Nestorian branch of the Christian church (7th to 10th, and 13th to 14th centuries, see NESTORIANISM); Manichaeism (7th to 9th centuries, see MANICHAEANS); Judaism (9th, 11th to 20th centuries); Islam (8th to 20th centuries); Roman Catholicism (13th to 14th, 16th to 20th centuries); the Greek Orthodox Church (17th to 20th centuries); and Protestant Christianity (19th to 20th centuries).

HISTORY

The actual history of the Chinese begins about 1300 B.C.; for recently excavated materials show inscriptions which permit that approximate dating. Before that time, however, people had lived long on Chinese soil, and had slowly evolved from ancient prehuman types to modern men and women, possessed of a fair degree of culture. That evolution never ceased throughout the centuries to follow. See Table 3 for a chronological chart of Chinese history.

Hominids.—The earliest manlike creature whose bones have been found lived before any similar folk who have been discovered to date in Europe, possibly a million years ago. The evidence, which comes from caves of a hill site 37 miles southwest of Peking, shows that he knew how to walk erect, could hunt and slay wild animals, was acquainted with fire, and had developed some skill in making tools out of stone, bone, and horn. He subsisted mostly on meat and may even have been able to speak. See MAN, PREHISTORIC RACES OF—*Peking Man*.

Old Stone Age Man.—In the course of the last 100,000 years the possible descendants of these hominids of the species, called *Homo sapiens*, were spread over a fairly wide area, for their remains have been found by scientists in Manchuria, Mongolia, and north China. Similar evidence has been reported by Russians in Russian Turkestan and Siberia. By this time their craftsmanship had improved, as evidenced by drinking horns cut out of spines, kitchen knives and needles fashioned out of bones, and even shells and teeth made into articles of adornment which have been picked up in sites of their habitation.

Late Stone Age Man.—After several tens of thousands of years human life for a time became intolerable in northern Asia. It was probably because of glaciation in Europe and to a lesser extent in western Siberia, when there were generated winds of great velocity which picked up the good soil in Sinkiang and Mongolia, scattered it over northeastern Asia, and thus formed the Tarim and Gobi deserts and the loess highlands of north China. Where man went in this interval, around 25,000 to 20,000 years ago, we do not know. Some people doubtless found refuge in south China and the Malay Peninsula; others in the Japanese islands; others began the drift into the extreme northeast, and thence to Alaska to begin the peopling of the Americas. By the time the great winds ceased, and the loessification was complete, human beings again returned to China, and began to fish the rivers, hunt in the mountains, and test the soil.

The oldest site so far found (in west central Shensi) is dated tentatively at 6000 B.C. It is characterized by better tools, made of stone, bone, and shell, coarse pottery vessels with pointed bottoms, the bones of pig (the first domesticated animal apparently), and pit dwellings in sufficient number to suggest communal life. For the next 3,000 or 4,000 years men and women in north China, Manchuria, Inner Mongolia, and possibly (to a less extent?) south China developed without significant use of metal, improving their manufacture of tools and pottery, beginning the production of millet, and possibly, toward the end of this period, of hemp, wheat, and dry rice, and domesticating the dog. Among their tools now were a stone-bladed hoe, ax, knife, bow and arrow, a contrivance for spinning thread, and a potter's wheel. While most pots were handmade and gray in color, some (found in the Hwang Ho Valley and to the north) were wheel-made and buff to red-brown in color, frequently decorated with geometric designs, a characteristic common to pots of like antiquity found in Chinese and Russian Turkestan, India, Baluchistan, and Iran. At the very end of the Stone Age a black wheel-made pottery appeared in many sites in eastern China, from the Hwang Ho basin south to Hangchow Bay. The people who devised this ware

lived in small villages near streams and were fundamentally farming folk. Besides the pig and the dog they had other domesticated animals: cattle, sheep, and horses. To heat their homes of circular pits some used oblong stoves. Their diet included shellfish, and they made special use of shells as utensils and decorations.

Bronze Age.—Beginning about 2000 to 1800 B.C. a new development characterized by the use of bronze implements, of wheeled vehicles, and of script is apparent. Whether these were intrusions or not is undetermined, but certainly is possible. All these things had been known for a millennium or two in western Asia and in the Indus Valley. Also about this time the first imperfectly recorded government is said to have held sway in part of the Hwang Ho Valley (the Hsia; approximate dates: 1994–1523 B.C.). Certain bronze vessels, occasionally inscribed with a single character, found in ancient tombs and now deposited in museum collections, may derive from this age. We can only aver that the recent great discovery of the last major capital of the next ruling house (the Shang; dated approximately 1523–1027 B.C.), with its finely executed bronze vessels and weapons, chariots, sculpture, and writing, indicates that there must have been people in China making prototypes during the half millennium or so prior to about 1300 B.C., when the capital was first occupied. The Shang government held sway over an area the limits of which depended on the fortunes of war. It was centered for its last three centuries at a spot near modern Anyang, Honan Province. At the height of its power the area possibly reached from the hills north of Peking to the Yangtze Valley in the south, and from the coast on the east to the neighborhood of Kansu; at its depth the area probably contracted to the immediate region around the capital. It had many enemies on whom it warred frequently, for reasons of self-defense and for tribute of slaves and booty. The government required a considerable bureaucracy and priesthood, put up a number of state buildings and temples, and indulged in frequent religious rites. The king worshipped Ti (an ancestral deity?) and other gods of lesser degree. Through priestly diviners he often consulted the oracle, and hence—as questions and replies were written on tortoise shells or animal bones—a great deal of valuable information concerning the life of the period has been preserved. While the royal household and its retainers hunted, did battle, and performed elaborate ceremonies, the common people probably went on living much as their forefathers had done. Their principal interest still was agriculture; secondarily they were concerned with animal husbandry. A special luxury industry which was developing (possibly among the women particularly) was silk weaving. Besides farmers and cattle breeders there must also have been craftsmen to manufacture articles of stone, bone, ivory, bronze, furs, and pottery (of which a beautiful white variety now appears), and merchants to deal in imported goods. The house of Shang collapsed when a powerful people on the western frontier, in alliance with several other tribes, beat it into submission, destroyed its capital, and scattered some of its adherents to the south, north, and east.

The Chou, 1027–256 B.C.—This people, probably also Chinese, but living on a lower cultural level than those dwelling near Anyang,

had as its ruling family the Chou. They came from the northwest, were inured to war, and possibly lived more off flocks and herds than by farming, at least at first. They installed themselves in the northwest, near modern Sian, and, with the assistance of their allies, ruled a territory even larger than that of Shang at its height. Until the beginning of the 8th century the heads of the house of Chou were able to keep their feudal lords in check and hold the loyalty of the rank and file. Friction then arose, several chiefs defied the reigning king, and in 771 one of them, with the help of an alien horde, rose in successful rebellion. The king was slain, and his court removed to central China near modern Loyang. Kings of the Chou house, however, continued to succeed one another for more than 500 years. Lords of feudal territories appealed to them to settle questions of succession and of religious observance; but their military power, and hence their ability to govern, had come to an end. Their one-time vassals were now the real rulers of China, each, however, in his own domain. At first these states were fairly numerous, but with few exceptions the weaker were rapidly absorbed by the stronger until only those most able to defend themselves remained. This was achieved not merely by force of arms but also by the erection of defense walls, by the art of diplomacy, and by the alliance of several states for varying periods of time. By the middle of the 3d century B.C. the kingdom of Chou was eliminated altogether, the once unimportant state of Ch'in was in a dominant position in the northwest, and other states in the east and in the Yangtze Valley were joined in conflict for complete domination. Ch'in was successful, and launched an era in Chinese government which lasted until modern times.

The Chou period has long been regarded by the Chinese as their classical age. Literature, both prose and poetry, then emerged for the first time, the earliest essays at historical writing were attempted, and a wide variety of ideas were set down by schoolteachers, states' advisers, and independent thinkers to baffle and instruct their followers. Most significant (for the future) of the schools which developed as a result of these philosophic utterances were the Confucian, which upheld the standard ethics of the ruling class, the Lao-Chuang (or Taoist), which was individualistic, mystical, and anarchical, and the Legalistic, which promoted ideas resembling the Fascist of modern times. Besides the literary and conceptual, many other developments are to be noted—in agriculture, flood control and irrigation, military techniques, diplomacy, astronomy, and such arts as lacquer, jade carving, bronze mirrors, and gold ornaments.

The Ch'in, 221–207 B.C.—The Ch'in created the first empire. Whether this had Western inspiration we shall probably never know, but there are striking similarities between the creation of the first emperor (Shih Huang Ti, r. 247/246–210 B.C.) and those of Darius in Persia and of Chandragupta in northern India. He abolished the feudal system, and instead divided the country into 36 provincial areas, later increased to 41 as he expanded his dominion. He developed a number of great highways leading to his capital (not far from Sian). Axles of wheeled vehicles were made uniform; so also were laws, weights, measures, and even the way to write. Great public works, some initiated by

his predecessors, were continued; namely, irrigation, canal building, and a long defense barrier, in part connecting older walls, in part new. Taxation, monopolies over iron, salt, and coinage, and conscription of men for labor and military service, all were functions of the central government alone. Members of aristocratic families were forced to move to the capital where they would be under the eyes of the court; much of the literature written before this time was assembled and burned; populations were transferred from one area to another, partly to ward off possible rebellions, partly to fortify and guard the long frontier; merchants were discriminated against in favor of farmers and craftsmen; and the Hsiung-nu (or Huns) in the northwest—long a potent enemy of the Chinese—were made to evacuate the area within the great loop of the Hwang Ho. The rule of Ch'in collapsed on Shih Huang Ti's death, but many of the innovations of this first emperor's house were continued, with modifications, for a long time thereafter. He had embittered the aristocrats, incensed the political theorists, and overburdened the poor; but the people enjoyed unification well enough to make a single China their continuing goal for two millenniums to come.

The Earlier Han, 202 B.C.–9 A.D.—After a few years of anarchy one leader, Liu Chi (or Liu Pang, r. 202–195 B.C.), emerged to establish his family in power. A man of lowly birth, he was nonetheless skilled in military strategy, and not without wisdom in politics. He re-established the capital in the northwest, near Sian, reconquered all but the extreme southland of the Ch'in empire, and sought (after 196 B.C.) for able men to aid him in government. These were for the most part men from substantial families, and were trained in history and in the literature of the Confucian school of thought, which upheld monarchical rule, believed in justice, and strove for order and peace. So conspicuous was their talent for maintaining the dynasty that recruits for the bureaucracy came to be drawn almost wholly from their ranks, a factor which determined the setting up of tests in 165 B.C., and especially after 125 B.C., for their selection. This came to be a distinct and valued, though often over-elaborated, feature of Chinese life later on. The first emperor of the Han dynasty tried not only to pacify the country he had won by force of arms but also to quell the enemies on his frontier. The most formidable of these were the Hsiung-nu. In 201 B.C. they swarmed down over the barrier erected by Shih Huang Ti and would have annihilated the emperor and his army had he not submitted to their terms. It was not until eight decades later that Chinese armies were able to best the Hsiung-nu. During these 80 years the Chinese were intermittently at their mercy and forced to pay tribute in kind. In fact, until fairly modern times, the north and northwest border was constantly an area of great potential danger.

Following the Hsiung-nu, the Turks, Tungus, Tatars, Mongols, and Manchus successively hammered at this gateway. Only the Japanese in recent centuries have been a constant threat to the coast. In the decade beginning 128 B.C. the ruling Han emperor, Wu Ti (r. 140–87 B.C.), sought alliances with central Asiatic peoples against the Hsiung-nu. This effort, though without initial success, brought Chinese envoys, followed by soldiery, into touch with lands and

peoples in central Asia and western Turkestan, and their reports induced the court to take over as colonies some of the lands of the great corridor leading from China to the Oxus River (now Amu Darya). From this point on, if not hitherto, the Chinese and the people of western Asia were in direct and fruitful, though intermittent, contact. Nor was this the only area of expansion. Beginning 111 B.C. the Chinese reconquered the region around Canton, which the Ch'in had first invaded, and the house of Han sent envoys to many of the lands bordering on the Indian Ocean. Another colonizing force went to the northeast and established a center near modern P'yöngyang, in Korea. In all three of these regions, central Asia, Indochina, and northern Korea, modern archaeologists have succeeded in uncovering indubitable evidences of Chinese settlement in the 1st century before the Christian era.

An Interregnum: the Hsin, 9–23 A.D.—

After two centuries of rule, court and palace politics so weakened the Han that an able minister, Wang Mang, was able to fly in the face of precedent and set aside the titular emperor. By every means within his reach he tried to keep himself in power and raise money for political ends. Word of his difficulties with the moneyed class in due course reached south and central Asia with the result that both colonial regions were temporarily lost to China. After a tumultuous regime he was slain by a merchant, and anarchy again darkened the scene.

Later Han, 25–220 A.D.—A scion of the house of Han became emperor two years after Wang Mang's death, and transferred the capital to Loyang in central China. For some years the government's main concern was the pacification of various parts of the country. Then the empire moved to recover some of its more distant possessions. Tonkin, Annam, and the island of Hainan were subjugated in 42–43 and combined to constitute a province of China; it continued so with but few breaks until the 10th century. During the last three decades of the 1st century small forces pushed their way into Central Asia, forming agricultural colonies which kept in subjection the little states flourishing around the oases, and held the Hsiung-nu and other tribesmen in Mongola at bay. The Chinese even crossed the Pamirs, and for a few years after 90 A.D. exacted annual tribute of the Kushan kingdom ruling in Afghanistan and northwest India during the first two centuries of our era. The settlements in south Manchuria and parts of Korea remained in Chinese hands, attracting occasional visitors from the little known islands of Japan. Direct communication between the Chinese capital at Loyang and the Island Court began in 57, if not earlier. After a propitious start during its first 70 years, the Later Han began to decline when succeeding emperors lost their hold through intriguing eunuchs and palace women. In 184 A.D. the peasants, harried by bad government and by a series of natural mishaps, revolted. During the upheaval which resulted military officers rose to power, and vied with each other for supremacy. In 220 the emperor, for years only a figurehead, was deposed and the fiction of Han extinguished.

So proud have the Chinese been of the achievements of this long period that they often call themselves Sons of Han. The imperial house at its two high points controlled an area greater in extent than ever Rome possessed in its most

flourishing days. To manage this region it developed institutions of government which persisted for a long time. So great did the demand for learning become, largely as a result of the establishment of the civil examinations as a door to official appointment, that 30,000 students are said to have been in attendance at the college of doctors at the end of the 2d century A.D. A great search for the literature of Chou times had been initiated in the 2d century B.C. That literature was copied extensively and commented upon; parts of it became the canon of the two leading schools of thought: the Confucian and the Taoist. Two historians, Ssü-ma Ch'ien (145–?87 B.C.) and Pan Ku (32–92 A.D.), left works which became the first and second of a remarkable series of dynastic histories. Science, music, art, and industry were all enriched by native invention and borrowings from outside.

The Three Kingdoms, 220–280 A.D.; Six Dynasties, 265–589 A.D.—China fell into three parts (Wei, Wu, and Shu) under competing leadership. Difficult living conditions everywhere drove thousands of families to migrate to the less settled areas of the south; forced others into banditry. After 265 one officer arose who attempted unification of power, but it was not for long. The restless tribespeople of the north and west, though constantly at odds with each other, took advantage of the chaos in China to carve great sections of the country out for themselves. Broadly speaking, the Chinese ruled in the south, while men of Hsiung-nu, Turkic, proto-Mongol, and proto-Manchu blood were lords of the north and northwest. The basic population was Chinese, but it became rapidly infused with non-Chinese blood. The bureaucratic government of Han times was in part displaced by barracks rule. Selection of men for office through examination gave way before selection by recommendation and other less expert means. The Confucian way of life, characterized by order and founded on the aristocracy, fell in favor before Taoism, a cult quite as Chinese and based on anarchy. Buddhism, stemming from India and overlaid with Iranian and other non-Indian ideas, penetrated every corner of China and commingled with Taoism until jealous Taoist leaders forced a schism. Politically these centuries are barren; culturally they are rich. Fresh religious experience, new forms of literature, maturing skill in sculpture, painting, and calligraphy, developing uses of paper, invented about 100 A.D., advances in agriculture, shipbuilding, medicine, and other lines of human endeavor tell of the vitality of the age. The end to disunion came when Yang Chien (Wen Ti, r. 589–604), an able officer of one of the northern houses, deposed its boy king, and extended his control to the south.

The Sui, 590–618 A.D.; the T'ang, 618–906 A.D.—Yang Chien's dynasty, the Sui, lasted only two full reigns, but—like the Ch'in before it—left enduring accomplishments. Besides reuniting the different parts of China, it expanded China's borders in the south, invaded Formosa and the Pescadores, sent missions to the East Indies, forced some of the chiefs of the Eastern and Western Turks in Mongolia and Ili into submission, and drove a Mongol-speaking tribe from Kansu into Tibet. Only in Korea were Chinese invading armies repulsed. The Great Wall was refortified, state grain depots were constructed at the western and eastern capitals of Changan and Loyang, which were themselves re-

built, a third capital near the mouth of the Yangtze was brought into being, roads and—even more important—waterways were improved and greatly extended, and a bureaucracy was re-established. The dynasty ended abruptly on the outbreak of a revolt by the Eastern Turks, followed by rebellion at home.

Two high officers, Li Yüan (Kao Tsu, r. 618–626) and Li Shih-min (T'ai Tsung, r. 627–649), father and son, seized the opportunity to establish themselves in power. Their house, the T'ang, carried on the high traditions of the Sui until, after several decades, China reached one of the highest points in its political history. The country was divided into provinces, land redistributed, education popularized, the examinations for civil office were put on the best basis they had ever been, the official religion—starved during four centuries of misrule—was encouraged, canals and irrigation were developed, the laws published. In foreign affairs the T'ang improved China's position in Asia. Protectorates were erected in Korea and Manchuria (668), and both north and south of the Tien Shan (about 657) in Central Asia; relations with princes of Tibet, Nepal, the Indus Valley, Persia, and Arabia signalized the dominance of China in world affairs. Despite signs of weakness this empire's eminence was not seriously challenged until about the middle of the 8th century. Then China suffered a series of heavy defeats in widely sundered regions. The Khitan in Manchuria disputed China's suzerainty on the Liao River, the Uigur Turks drove the Chinese from Mongolia (745), the Thai in the southwest subdued two Chinese armies in 751 and 754, and the Arabs trounced China's viceroy decisively near the Talas River in 751. This gave the signal to dissidents at home. The rebellion of 755–763 nearly prostrated the empire. It recovered some of its dignity for a while, however, though almost none of its wealth and colonial lands. A century later (875–884) another disastrous peasant rebellion, prompted by unjust administration, laid it low, and it was clear that the house of T'ang had run its course. The Sui and T'ang periods are notable for poets, sculptors, painters; for the slow development of printing by means of wood blocks; for the introduction of several religious cults of western Asiatic origin, which, however, were officially banned in the great anti-Buddhist persecution of 845, and but little affected Chinese mores and ethics. The T'ang also greatly influenced neighboring countries, Japan in particular.

The Five Dynasties and the Ten Independent States, 907–960 A.D.—As at the end of the Han, rival military officers struggled for mastery as the T'ang declined. No one proving dominant, the country fell apart. A pretense of empire was continued at the center. The Khitan of Manchuria seized a large area in north China in 907 and held it until 1125. The rest of the country continued in a state bordering on anarchy.

Partly because of these parlous conditions the printing of books of all categories proceeded apace. Literate folk both in secular and religious life did not want their literature to disappear; so they hastened to produce it in quantity and distribute it widely. Once begun, printing became highly popular and resulted in numerous collections of books in monasteries, academies, and the homes of the well to do, a fact which laid the basis for a renaissance in literature in the succeeding era. This in itself almost counter-

balanced the harsh political and social conditions.

The rise of nouveaux riches to power was probably responsible for one innovation which was to curse Chinese women for a thousand years: foot-binding.

The Sung, 960–1279 A.D., and non-Chinese Houses.—The next three centuries saw China again partitioned. Chinese governed in the south and center, but alien chiefs were in power in the west and north. An able civil and military officer of good family, Chao K'uang-yin (T'ai-tsu, r. 960–976) seized power in 960 in central China and consolidated all of the little states in the Yangtze Delta and beyond, as far south as Canton and Hainan Island, into one domain (the Sung). Except for one disaster—in 1126, when the capital at Kaifeng was invaded, the emperor and 3,000 of his courtiers whisked off to exile in Manchuria, and the northern frontier depressed—the Sung lasted for the traditional period of a strong dynasty, kept its enemies at bay with a fair degree of success either by diplomacy (and purchase), or by force of arms, and improved its commercial relations overseas. The Sung Chinese became for the first time a seafaring people to be reckoned with, put the magnetic needle to use on ships, distributed such favored Chinese products as porcelain around the rim of the Indian Ocean, founded new cities, constructed many public works such as city walls, flood controls, and canals, and fostered the arts and, to a less degree, science and thought. In the north the Khitan, a people of Mongol origin, founded the Liao kingdom (907–1125), and not only ranged over north China, Manchuria, and Mongolia, but also treated the Tangut and Koreans as vassals, and had formal relations with Arabia and the islands of Japan. Their administration was in a state of collapse when another rude people from still farther north, the Jurchen, seized the opportunity to strike and ousted them from eastern Asia. The empire which followed for more than a century (1115–1234) went by the name of Chin. On the western flank, near the end of the Great Wall, former Chinese lands were occupied by a Tibetan people, the Tangut, who evolved from a horde into a kingdom around 990, and from that to an empire (the Hsia) in 1032. They were a power in that sector, and sometimes a troublesome and exacting neighbor, until the great Mongol Genghis (Jenghis) utterly defeated them in 1227, and annexed the territory.

All three of these folk when they occupied parts of China were on a lower level of civilization than the Chinese, and to some degree encouraged their own institutions and prohibited Chinese. But the fact of environment served to break down their resolve to remain aloof and unsullied by China's culture. An agricultural economy, and not a pastoral or forest, was clearly required in the Hwang Ho valley, and the village and town complex of the region called for a bureaucracy based on the Chinese model. With these inevitably came the religious and literary institutions of the Chinese, so that, while the people of the north and west generally lagged behind those of the south, important cultural advances were made there as well as under the Sung. The Tangut, for example, built up a literature in their own language through translation from the Chinese, and printed much of it, while the people under Jurchen rule boasted of a large number of playwrights (most of them Chinese) and an active theater at Yenching (modern Peking). In

war they all constituted formidable enemies. They built up excellent organizations of troops, both mounted and foot, and were not slow in trying out and adopting new equipment. It was in this age that the hand grenade and the bombard blossomed from the firecracker and the ballista. The Mongols probably borrowed much of their tactics and matériel from the older and more experienced fighting machines south of the Great Wall, against which they fought before deploying into the west.

The Yüan, 1260-1368 A.D.—The people of Mongolia were a scattered lot of tribesmen during the major part of the 12th century. By 1204 a single man, Temujin, shortly to be called Genghis, had whipped them into a solid, hard-fighting unit. He turned on the Tangut in 1205 and on the Jurchen in 1209. The former became vassals on his death in 1227, and Korea and north China succumbed to his successors in 1231 and 1234, respectively. Sung China constituted the hardest nut to crack, in part because of strong resistance, in part because its terrain was not suited to the type of fighting in which the Mongols excelled. It finally broke, after many bitter sieges, in 1279. So, for the first time in history, did all China come under alien domination. It constituted merely a part of the huge empire of the Mongol khan and first emperor of the Yüan (Kublai, grandson of Genghis, r. 1260-1294), but he liked it so well that Khanbalik (Peking) became his winter capital and he lived in China probably as much as he did in his native land.

With the Mongols were many peoples of foreign birth and training, upon whom they leaned for advice and service. By the same token, they found the Chinese useful in distant parts of their realm, and dispatched them over the imperial highways built across Asia to Novgorod, Moscow, and Tabriz. Chinese engineers improved the irrigation of the Tigris-Euphrates alluvial plain, serviced the catapults and flame-throwing devices in Hulagu's campaign in western Asia, and built the ships which took a branch of Kublai's army to Japan. Chinese paper money for a short while became standard currency throughout the Mongol world. Two branches of the Christian church, the Nestorian and Roman Catholic, together with Islam and Tibet's form of Buddhism, penetrated China. The last two remained after the ousting of the Mongols from China, as their connections with their mother lands held firm; the former withered away as the Chinese sought to remove all taint of the foreigner within their borders.

The Ming, 1368-1644 A.D.—Just as the southern provinces had been the last to fall into Mongol hands, they were the first to rebel. By the 1350's the Yangtze Valley was seething with revolt. By 1368, Khanbalik was reoccupied by Chinese forces, and soon the Mongols were obliged to withdraw on all fronts in the east, from Korea, Manchuria, Yunnan, and even their summer capital of Karakorum. The mighty Timur, or Tamerlane, tried to lead a Mongol army in 1404-1405 in the recovery of China but he died at the head of his troops when halfway across Asia. The rebel Chu Yüan-chang, who became undisputed master of China, was not a man of birth and breeding but, like the first of the Han, one of peasant stock; his parents had given him as a child in time of famine to a Buddhist monastery. He arose to leadership and established his dynasty (the Ming) by craft and brute force. It exercised its power, not only within the wall as far

south as Kwangtung and Yunnan, but also at times in Manchuria and Mongolia, for two and three-quarters centuries.

The third in the line was Chu Ti, the emperor of the Yung-lo period, 1403-1424, who in 1421 moved the capital from Nanking, where it had been established by the first emperor, to Peking. He increased the prestige of China and probably its wealth by sending embassies to neighboring lands (1403), followed by a series of six naval expeditions of unusual size and armament which visited the South Seas, India, and the Persian Gulf. These returned with a number of alien princes, ambassadors, and tribute to the Chinese capital, and collected a considerable body of information both curious and solid for the court. The seventh expedition went out in 1431 and came back in 1433. It was the last. By this time the emperor's advisers had turned isolationist, for reasons today only guessed at. Chinese shipping was confined to coastal waters.

When the Portuguese arrived in the Indian Ocean at the end of the century their principal rivals in commercial transport were the Arabs. The Portuguese touched China, near Canton, in 1514, later harrying the nearby coastal cities. They were followed in 1543 by the Spanish, who penetrated the Philippine Islands in 1565, the Dutch, who moved into Formosa in 1622, and the English, whose trading vessels came to Canton in 1637. Meanwhile, in 1431, Annam had procured its independence, and Japanese (and Chinese) pirates thrived in coastal waters until no port, even on the lower reaches of the Yangtze River, was safe from their depredations. Even the western and northern border became imperiled.

Tibet, after throwing off the yoke of the Mongols, had indicated its independence in 1413. The Mongols defeated a huge invading Chinese army in 1449 and a hundred years later penetrated the Great Wall region. The Russians, advancing swiftly across Siberia, sought contact with Peking in 1567 and again in 1619. The Japanese, resurgent under Toyotomi Hideyoshi, invaded Korea with an eye to continued empire, and were only forced out by Chinese and Korean armies in 1598 after six years of fighting. The Manchus, offshoots of the Jurchen, followed hard after, asserting themselves in the extreme north of their homeland, where they vanquished Chinese armies again and again until, in 1636, Manchuria was wholly theirs, Mukden (Shenyang) their capital, and they were in a position to raid north China with impunity. The court at Peking (the Ming capital after 1421), increasingly under eunuch guidance, was impotent, in spite of wise counsel from loyal statesmen. It aroused the hatred of many elements by playing favorites, misgovernment, heavy and often foolish taxation, hapless conduct of the war in the north, and its failure to suppress piracy on the coast. Civil strife became common in the early decades of the 17th century, concluding with a rebellion which removed some of the western and central provinces from Ming control in 1640-1643. Peking was invaded and the last of the Ming emperors took his life in 1644.

Politically, China was in the doldrums. Socially, intellectually, and culturally the picture was not nearly so dark. A public works program at the outset of the Ming restored China's productivity after the devastation of the anti-Mongol campaign. The rebuilding of city walls

improvement of the system of waterways, construction of countless new bridges, defenses, and places of beauty marked the early decades. The civil service examinations were restored, after a break lasting two or three generations under the Yüan. The planting of sorghum and cotton, both lately introduced from India, was encouraged, and, after the middle of the 16th century, the cultivation of New World plants: maize, peanuts, sweet potato. Tobacco, at first prohibited, made its way against all opposition. Encyclopedias, both great and small, and collections of reprints saved much of antique learning that might otherwise have been lost. New investigations in many fields pushed forward the boundaries of knowledge—in music, language, geography, the classics, *materia medica*. A number of works were printed with movable type, but wood blocks for this purpose were generally favored. Fiction at last came into its own, and the theater developed new genres. Buddhism and Taoism claimed many loyalties but their sun—for men and women of intellect—had practically set. Confucianism set the standard for products of schools and for men in official life. Painting and porcelain were the two chief arts. After the reappearance of Roman Catholicism, first in the south (Macao, 1579), then in the north (Peking, 1601), a number of open-minded Chinese were impressed and affected by the learning and character of the missionaries from abroad. Some were converted; many more were influenced by their writings on knowledge new even then in Europe.

The Ch'ing, 1644–1912.—The Manchus made a full-scale invasion of China only when they saw that its people were hopelessly divided, and after they had consolidated their hold on Inner Mongolia and Korea. The rebel emperor in Peking had only a few weeks on the Dragon Throne before he had to flee for his life. The Manchus, joined by Chinese renegades, swept on through the provinces against bitter though ineffectual opposition, the last Ming pretender being ousted in 1659. Revolts on the southern coast and interior provinces were finally crushed in 1683. About a century of peace ensued, a century characterized by a last considerable burst of native culture, supported by Manchu arms. The boundaries of empire were stretched to include the whole of eastern Asia from Hainan to Sakhalin and from Korea to the Pamirs. Commercial relations with Europe and the New World, largely through such ports as Canton, Macao, and Manila, increased and grew steadily more profitable. Population rose steeply. The minor arts were much in demand. Native thought, stimulated first by anti-Manchu feeling, and next by introductions from the West, had another impressive renaissance. The duration of this was shortened, however, by imperial disapproval and censorship. Great compilations were again published under court sponsorship; also many private works on historical criticism, mathematics, antiquities, and the like.

The Manchus continued a government much like that of the Ming, insisting, however, on the maintenance of guards of Manchus, Mongols, and Chinese loyal to the throne in key cities scattered throughout the country. Their fault lay in allowing the governmental machine to deteriorate, in refusing to recognize at the zenith of their power the growing discontent within their own borders, and the burgeoning strength

of generally despised states abroad. The suppression of tribespeople in the southwest and mishandling of Moslem adherents in the west resulted in rebellions which were intermittent after 1774. Secret societies banded the peasantry into powerful antigovernment forces. For a hundred years the Manchus had to cope with these revolts both in China Proper (to 1873) and in Central Asia (to 1878). Better led, and unimpeded by foreign support of the imperial armies, the rebels might have succeeded in driving the alien conquerors back to their homeland. It was not to be, however, until the beginning of the 20th century, after another outbreak (1899–1900) by a secret society (the Boxers)—adroitly turned in full against the foreigner—had shown the utter collapse of Manchu authority and ability to govern.

The nations of Europe made clear from the beginning of this dynasty their determination to trade and have other dealings with the people of China and their overlords. At first the interchange of goods in southern ports (with Spanish, Portuguese, Dutch, and British) and on the northern frontier (with the Russians) was fairly brisk, and the Manchu welcome to European embassies and Roman Catholic missionaries cordial. Coolness came when the court was angered at the arrogance of many Europeans and at what it took to be a slight from the Holy See. Bitterness too arose over the unwillingness of the foreign trader to be governed by imperial regulations at the ports, particularly when it was discovered that there was a flight of Chinese currency from the mainland.

A special grievance was that of opium imported on Western vessels from India and Turkey. Sale of opium was forbidden by decree in 1729, and its importation prohibited in 1796. Nevertheless, British and other vessels, including American, insisted on the right to carry it to Canton where it found a ready, if illicit, market. This conflict of wills exploded finally in a short war (1840–1842), localized in the south, won by the British, at the conclusion of which Hong Kong was ceded and 5 ports were opened to trade. (See also OPIUM TRAFFIC.) Other nations seized the opportunity to gain the same and other advantages, until within two decades 11 additional ports were opened, extraterritoriality of their nationals was granted, a maritime customs service in charge of a Westerner was created, legations were established at Peking, the importation of opium was legalized, and Catholic and Protestant churches were permitted to carry their evangel into the interior, own property, and engage Chinese to teach their people the language of the country (latterly forbidden).

The Industrial Revolution on both sides of the Atlantic was now in full swing, and it boded ill for any country whose defenses were down. In 1860, when the Manchu government blocked the ratification of the British and French treaties, duly negotiated two years earlier in Tientsin by James Bruce, 8th earl of Elgin (q.v.) and Baron J. B. L. Gros, expeditionary units of the French and British armies forced their way to the gates of Peking, and looted and set fire to the ^{palaces} palaces of the imperial family outside the city.

In the next few decades it seemed likely that China would be partitioned by the strongest powers. Areas all around the country fell away: Indochina, Burma, Formosa, and the Pesc were appropriated by France, Britain, and Ja

Russia penetrated the valley of the Ili. Japan successfully ousted Manchu troops from Korea. There was a scramble for concessions by Great Britain, Germany, Russia, and France. Sizable indemnities were exacted. Thousands of Chinese peasants were taken abroad by labor pools and underwent lives of virtual slavery despite protests from Peking.

The United States Secretary of State John Hay (q.v.), following a private British suggestion, proposed in 1899 to Great Britain, France, Germany, Russia, Italy, and Japan that China be regarded as an open market for international commerce, and that these powers, together with the United States, join in helping China regain its independence and reform its government. Even before these proposals were formulated a few high-minded Chinese, notably K'ang Yu-wei and Liang Ch'i-ch'ao, had sought out the Manchu emperor, Tsai-t'ien (reign name Kuang-hsü, 1875-1908), in the palace (1898) and persuaded him to issue a series of edicts promoting a new education, a new set of examinations for civil service appointments, an army drilled by Western methods, judicial reform, encouragement of agriculture, industry, and engineering, translation and distribution of important Occidental books, and other reforms. The people were unprepared for so drastic a change.

The empress dowager, Tz'ü Hsi (Hsiao-ch'in, regent 1862-1873, 1875-1889, 1898-1908), a shrewd and calculating woman then in retirement, who had entered the imperial household as concubine to an earlier emperor, promptly dethroned her nephew, canceled the proposed reforms, and executed the reformers or drove them from the country. The stage was set for almost anything to happen. The society of Boxers (largely effective in the north), whose original aim had been to overthrow the Manchus, provided the answer by stirring up ill feeling against the foreigner; the Imperial Army joined forces with them. In June 1900 they attacked the church centers and the legation quarter in Peking and the foreign community in Tientsin, and massacred many innocents elsewhere, mostly in north China. By the end of the summer the foreign powers had come to the rescue of the besieged and brought peace; their representatives were soon to sit down to discuss the indemnities and penalties.

The experience, costly though it was, brought the court and the people to their senses. Long overdue reforms were launched. Thousands of students went abroad, particularly to Japan, to study politics, law, engineering, medicine, and other subjects. Trade developed in volume. Foreign eleemosynary work increased. Efforts were even made to democratize the government, but they were started too late to save the Manchu. His day was done. The war between Russia and Japan (1904-1905) deprived him of Korea and Liaotung. The almost simultaneous death of the empress dowager and the emperor (1908) removed an able, if unscrupulous, woman and an ineffective idealist from the seats of power. The reformers exiled abroad and many of the students in Tokyo, Paris, and elsewhere worked unceasingly to rid the land of the alien incubus.

The Republic, 1912.—The many dissatisfactions came to a head in September 1911 over the railroad construction program in Szechwan. When many innocent people who protested against the way it was handled were wantonly killed by the soldiers of the governor general at Chengtu,

the whole province burst out in revolt. Within a month (October 10) the revolt had spread down the Yangtze River to Wuchang, another provincial capital. (The double tenth celebration dates from this event.) Province after province in south China followed suit. Many Manchu settlements were put to the sword. The recently organized National Assembly in Peking showed its spirit by demanding the resignation of Prince Regent Ch'un (Tsai-fêng). Yüan Shih-k'ai, a military officer and idol of the army, was made premier. Outer Mongolia declared its independence. Meanwhile Sun Yat-sen, chief agitator abroad for a new China, had returned to Shanghai and on Jan. 1, 1912 had been inaugurated at Nanking as president of a coalition of southern provinces. Negotiations between Yüan and the imperial family on the one hand, and between the northern and southern provinces on the other, resulted in the abdication of the Manchu house, the resignation of Sun, the inauguration of Yüan as president of China, and the retention of Peking as capital. The Chinese were at last technically masters in their own land.

Unhappily, a crisis was taking shape abroad that was to affect the world. Within a few weeks of the outbreak of World War I, Japan demanded from Germany the surrender of its property on the Shantung Peninsula, and followed up the demand with force. China protested its neutrality and asked for the removal of Japanese troops. Japan retaliated with the secret presentation to Yüan himself of a series of demands, in five groups, most of which were a serious encroachment on the sovereignty of China. This was an extraordinary affront to a nation, not at war, supposed to be independent. The secret became quickly known, the people were indignant, the United States declared to both nations that it refused to recognize any agreement affecting its own treaty rights or impairing the political and territorial integrity of the new republic, and China even made counter demands on Japan which it was powerless to enforce. Nonetheless, the republic capitulated in May 1915 to a modified set of demands. With Europe embroiled in war, and the United States unprepared to settle such a question by resort to arms, Japan used its opportunity to the utmost, even proceeding in 1917-1918 to make secret treaties with Great Britain, France, Russia, and Italy to support its own position in return for military, in particular naval, assistance. These treaties were revealed only at the peace conference at Paris.

At the same time China's domestic affairs were proceeding badly. The ambitious Yüan made no disguise of his contempt for parliamentary institutions, and tried to make himself emperor. Pamphleteers, notably Liang Ch'i-ch'ao, denounced his schemes. The southern provinces rose in insurrection. Yüan died (1916) in the effort. Although a series of men followed him as president, the country was disunited for more than a decade thereafter. Yüan had built a personal, rather than a national army. Other provincial leaders followed suit. There was a jockeying for power all over the country; in the south, southwest, west, center, east, and north. Some of the army leaders, known as war lords, were of peasant, even bandit, origin and were interested in little more than personal aggrandizement, profit, and sensual satisfaction. They taxed the people in some areas mercilessly, insisted on the planting and sale of the opium

poppy to fill their own coffers, and let justice go by the board. No wonder that communism fed on such a situation and took root in certain areas. When the Nationalist (or Kuomintang) Army, under Russian Communist guidance, overran Kwangtung and Kwangsi (1924-1926) and marched northward from Canton in 1926, it took advantage of these conditions and rapidly organized the workers. By 1928, however, the conservative faction, under Chiang Kai-shek, had won the day, and was freezing Communists out of high places in the Kuomintang. Chiang had also won as allies several of the war lords, including one in the three northeastern provinces (Manchuria), and was able to move with impunity into Peking (then renamed Peiping). Nanking was made the capital. It took, however, another decade before all the war lords were united (even superficially) under his leadership against a single enemy—Japan. The Communist faction, which he forced out of pockets in south China into the northwest, after bloody fighting, joined him in a common front for a time but was shortly alienated by repressive measures.

While China was suffering in the effort to convert its government from Manchu to Chinese, and from empire to republic, events abroad were affecting its development. In 1917, China agreed to the United States proposal to enter the war against Germany. This took China out of the area of German intrigue, cut off Germany from certain supplies, provided for the internment of German and Austrian nationals and vessels in Chinese ports, and made for some aid in the Siberian situation. Militarily China did nothing although upwards of 200,000 Chinese served in labor battalions in France under French, British, and (at the end) United States direction. Joining the war effort did mean, however, that China would have a say in the peace. Its representatives at Paris strongly opposed Japan's contention that all of Germany's rights to Shantung belonged to Japan by right of conquest, and refused to sign the Treaty of Versailles as a consequence. But China did sign the treaty of peace with Austria, and so became a member of the League of Nations.

Two years later (1921-1922) representatives of China and Japan, brought together by the United States at the Washington Conference on limitation of armaments, were able finally to agree on ways of settling the Shantung issue. Other points brought up indicated that foreign nations were prepared to consider the restoration to China of full sovereignty. In the next few years these were dealt with, namely, the withdrawal of foreign post offices, the relinquishment of wireless stations, and the restoration of tariff autonomy (1929). In the same decade too the national government likewise asserted enlarged control over the maritime customs, and regained such foreign-administered areas as Weihaiwei, and parts of Hankow, Kiukiang, Tientsin, and Amoy. In 1926 three Chinese members were included on the governing body of the International Settlement of Shanghai, and in 1928 new civil and criminal codes were put into effect. In the same year the Chinese extended their jurisdiction over the courts in Shanghai. The relinquishment of extraterritorial rights by the United States and British governments was under negotiation at the same time, but not formally put into treaty form until 1943 because of the outbreak of war with Japan in Man-

churia. Similar treaties were negotiated with other powers. China had succeeded in removing practically all limitations to its sovereignty within a generation.

Japan after acquiescing for about a decade in China's effort at control within its own borders, suddenly turned on China in 1931. What determined this shift of policy is outside the scope of this article. (See *WORLD WAR II—Japan's Pattern for Conquest*.) Suffice it to say that Manchuria was invaded and the native city of Shanghai subjected to a brutal bombardment and assault. A commission appointed by the League of Nations failed in its endeavor to halt Japanese aggression. The truce of 1933 made Japan master of Manchuria (including Jehol) and of the eastern part of Hopeh. An uneasy situation continued as the Japanese smuggled large quantities of their own goods into north China, supported an unsuccessful invasion by Mongol troops of Suiyuan, established their control over parts of Chahar, and tried to subject Chinese officials north of the Hwang Ho to their own will.

By 1937 elements in the armed services and possibly as well in the Japanese government decided that the time had come to strike a stronger blow. China's unification by then was virtually consummated, and the Communist forces had been driven out of Fukien and Kwangsi into northern Shensi and seemed even eager to accept Chiang's direction in a fight against Japan. Besides, the army had been partly modernized, several railroad lines and many motor roads had recently been completed and a few airlines established, the industrial output was increasing, and the currency had been reformed. The Chinese Republic was at the peak of its strength.

The blow fell in July when units of the Japanese Kwantung Army and Chinese forces clashed west of Peiping. For the first year, despite immense losses on the coast, from Peiping and Tientsin south, the Chinese stood up surprisingly well. Political leaders from Shantung, Yunnan, Kwangsi, and Szechwan pledged Chiang their loyalty and the Communists were enrolled in the National Army. There was wholehearted defense of one city after another. Supplies could still enter the port of Canton and utilize the railway running north to Hankow, which had become temporary capital since Nanking's capture in December. With Hankow's loss (1938) the war took a new turn. The capital was moved still farther up the Yangtze Kiang to Chungking. Lines of supply were difficult to maintain. Almost the whole of China's industrial plant, save what was transportable, had to be left behind. Until the summer of 1941, Russia shipped supplies across the Gobi, while the United States and Great Britain sent their supplies by way of Indochina. Then Japan forced Indochina to close the railway to Yunnan (1940), seized Hong Kong (December 1941), and occupied Burma (1942). The Chinese Army was back on its heels with virtually no munitions to wage a modern war.

Support from outside came slowly. By 1945, following victory over Germany, the USSR had penetrated Manchuria, and the United States Army and Navy were about ready to launch a full scale attack on the Japanese armed forces farther to the south. However, Japan capitulated before that moment came.

Tasks undertaken after Japan's surrender

included the disarming and repatriation of Japanese nationals, recovery of interior and coastal points long held by the enemy (Nanking became the capital once more), and arrangement with the USSR to reassume control over Manchuria. The last, in spite of promises by the Soviet government, could not be effected as long as the Nationalists were in power; only in February 1950 was a working agreement reached on this head between the new People's Republic of China and the USSR. Throughout the last months of 1945 and the whole of 1946 an attempt was made, largely under United States leadership, to restore the Communist-Kuomintang entente, so near rupture during the last half of the war. Gen. George C. Marshall, after prolonged effort, returned from Nanking to Washington in January 1947, sharply criticizing both the Communists and the reactionaries in the Nationalist government, and declaring that China's hope lay in "the assumption of leadership by the liberals in the government and in the minority parties" under the guidance of Chiang Kai-shek. This report ended all hope that peace might develop. Only civil war, it was clear, and the collapse of one side or the other, would bring unity.

Inflation, economic difficulties, shortages of many basic materials, limited transportation facilities, and misgovernment in places both high and low brought the Nationalists into low repute. Their armies succumbed to the Communists rapidly toward the end of 1948, sometimes without a fight, and by the end of 1949 were wearing the uniform of the victors or were in flight to border lands or to the islands of Hainan and Formosa. On Oct. 1, 1949, the Communists formally declared Peking (which resumed its old name) their capital and constituted their government as the People's Republic with Mao Tse-tung at the head and Chou En-lai as premier and foreign minister. By early 1950 the USSR, Great Britain, India, and other nations granted it recognition, although the officials representing China at the United Nations were still those appointed by the Nationalists. Meanwhile, Chiang Kai-shek and a considerable number of his supporters, both civil and military, remained ensconced in Formosa and refused to admit defeat. With a considerable supply of ships, airplanes, and modern armament they harassed China's coast, blockaded the ports, and bombed industrial and shipping centers from Canton to Tsingtao and threatened Tientsin and Hankow as well. These acts caused serious damage and made the new government's efforts toward physical recovery and economic stability difficult. On June 27, 1950, this situation changed when, after the outbreak of the Korean war, President Harry S. Truman requested the Nationalist government to cease its attacks and ordered the United States Seventh Fleet to patrol Formosa Strait to protect the island.

There have been many positive gains for China in the years since 1912, although war has destroyed or postponed some of them. The binding of women's feet has virtually disappeared, and women have won new independence outside as well as inside the home. Labor, always held in theoretical respect, but more often despised and maltreated in practice, is making a better place for itself. The queue, worn by men as a badge of servitude to the Manchus, disappeared. Government and private agencies have bestirred themselves in education, at

an ever-increasing tempo, until both men and women have been able to get a primary, secondary, and college education without leaving the land. In some fields, such as medicine, agriculture, business, law, engineering, and theology, it was even possible before 1937 to get satisfactory technical training in a few cities. The country was not ready, however, for compulsory education, and illiteracy was and is a major problem.

The written language, its usefulness for common intercourse at an end, was largely displaced by the vulgate, and many writings and textbooks appeared in the new medium. Publishing houses, with a large volume of business in all kinds of books, mushroomed in the port cities. Libraries, stocked both in the new learning and the old, flourished. Newspapers and journals, many of them fly-by-night and insubstantial, became very numerous; a few of them were serious molders of opinion or made contributions to literature and scholarship. Institutes of research, both in modern science—such as geology and medicine—and in antiquities—such as history and archaeology—were fostered by students returned from abroad, locally trained scholars, and foreign subvention. Commerce and banking on modern lines were widely introduced. Agriculture, mining, and industrial methods were improved, new seeds and livestock introduced; and a widespread effort to teach the masses the elements of reading and writing, sanitation, economics, and democracy began.

Many precious things of brick and marble, paper and silk, porcelain, jade, and bronze were destroyed by the Japanese during the war. For a short period thereafter there was evidence of an effort to reinitiate work in the ancient crafts, but the leaders of the new government put an end to them, encouraging instead basic industries, rural cooperation, and improved farming. They were concerned too with public health and removal of the causes of poverty, but the task of meeting the demands of the day were so insistent, the number of mouths to feed so many, and the tools and funds to work with so limited, that the reforms they hoped for might take a long time to carry out.

By 1950 a different China was emerging, with Communist leadership firmly in control of the country. Most of its domestic problems remained the same: how to develop a sufficient food supply; how to eliminate pestilence and lower both the birth and mortality rates; how to control the river systems and if possible turn them into instruments of power; how to exploit the natural resources for the general benefit; how to develop industry and communications; how to reduce illiteracy and provide genuine educational advantages for the worthy. In foreign relations its policy was closely knit with that of the Soviet Union, and its expansionist movements were bringing the world to the brink of a general war. In late October one army invaded Tibet against the sharp protests of the Indian government; in mid-November a far more massive force struck across the Yalu River and forced the almost victorious Republic of Korea and United Nations armies to give up their hard-won gains north of the 38th parallel; a third stood poised in the south, ready to aid their political allies in Indochina. A delegation sent from Peking at the end of November upheld its government's actions before the United Nations

and accused the United States for its actions in Korea and with respect to Formosa.

Professor of Chinese, Columbia University.

2. LANGUAGE. Chinese is one of the major languages of the world, spoken by approximately 450,000,000 people. It is the chief member of the Indo-Chinese family of languages, which also includes languages of the Thai branch, such as Siamese, as well as those of the Tibeto-Burman subfamily. The genetic relationship of Chinese to the Tibeto-Burman languages, however, has not been absolutely established. Although both Japanese and Korean contain many borrowed Chinese words, Chinese is not related to either of these languages.

Word Formation.—Chinese is often described as a monosyllabic language, but the validity of this statement depends upon what we regard as a word in Chinese. The language has two types of units, each of which has some, but not all, of the features of a word in other languages. The first type is the monosyllable, called in Chinese *tsü*, which almost always operates as a meaningful unit. Partly because the *tsü* is written with a single character, it is frequently mentioned in everyday speech. People talk about learning *tsü*, using the right or wrong *tsü*, paying so much for 10 *tsü* in a telegram, or receiving so much money per 1,000 *tsü* for contributing to a periodical. The second type is the syntactical unit. It can be spoken independently and combined with a high degree of freedom, and therefore acts more like a word in the linguistic sense. It may consist of a single *tsü* or of a close-knit combination of two or more *tsü*. In short, we can say that the Chinese language is monosyllabic or polysyllabic, depending upon whether we base our definition on the single root word or on the syntactical unit. In this article we shall speak of words in either sense, but we shall distinguish when necessary between root words and syntactical words.

The Chinese syllable has a rather simple phonetic structure. Except for a few words that

begin with vowels, each syllable begins with a consonant or a consonant cluster. The cluster is usually simple, consisting at most of a stop, a fricative, a spirant, and a semivowel: for example, *ts'u* (*ts'w-*) in *ts'uan*. There are no words of the *str-* or *spl-* type. Then there is a main vowel, with or without a final consonant or semivowel. In most parts of China there are only two semivowel endings, *-i* and *-u* (forming diphthongs like *ai* and *ou*), and three consonant endings, *-n*, *-ng*, and *-r*. In ancient times there were other endings—for example, *-m*, *-p*, *-t*, *-k*, *-b*, *-d*, and *-g*—but these have largely disappeared, although a few persist in the dialects of the southeast.

In addition to consonants and vowels, there is a third constituent element of the Chinese word. This is the height and movement of the fundamental pitch of the voice, known as tone. Tones have often been described as a device to distinguish words. This is true only in the sense that differentiation between vowel sounds is a device to distinguish the English word "met" from "mat," and differentiation between consonants is a device to distinguish "mat" from "mad." Actually, of course, the tones in Chinese have evolved from unpremeditated natural causes. The sounds of the four tones in Mandarin, or Standard Chinese, are (1) high level, (2) high rising, (3) low rising (or low dipping) and (4) high falling to low. Occasionally, words differing only in tone are etymologically related—for example, *hao*³ (good) and *hao*⁴ (fond of), which are related in somewhat the same way as "man" is related to "men." But the majority of words which differ only in tone are quite unrelated—*fei*¹ (fly); *fei*² (fat); *fei*³ (bandit); *fei*⁴ (waste, spend)—as in the case of "mat" and "met." In most parts of China there are four tones. The same words are usually grouped in the same class, but the pitch pattern of each class varies sharply from one locality to another.

Grammar.—Most Chinese sentences have a subject and a predicate, although minor sentences, corresponding to such expressions as "What a nuisance!" and "Never heard of such a thing," are less unusual in Chinese than in English. The subject in Chinese is literally the subject matter and need not represent the agent performing the action. For example, *cher yao k'ai p'u-tzü*, which is translated "They will open a store here," means literally "This place will open store," or more analytically, "As for this place, there will be opened a store." Within either the subject or the predicate the words are arranged in four main types of construction: (1) coordinate construction, often without conjunctions or even pauses, as in the expression *tung nan hsi pei* (east, south, west, and north); (2) qualifier-qualified construction, with the parts always in that order, as in *huai jên* (bad men) *hên k'uai tē p'ao* (very quick-ly run—run very quickly), or *kang tsou tē jên tē mao-tzü* (just left kind of man's hat—the hat of the man who has just left); (3) verb-object construction: *hsieh hsin* (write letters) or *wên t'a chao shei* (ask him look-for who—ask him whom he is looking for); and (4) verb-complement construction—*sao-kan-ching t'a* (sweep-clean it—sweep it clean) or *ta-p'o* (strike-broke—smashed).

The parts of speech in Chinese are similar in many respects to those in English, but there are two important differences. First, words denoting qualities do not have special grammatical

features of their own but behave like other intransitive verbs: *t'iar hao* (weather fine—the weather is fine). Secondly, there is a class of particles or enclitics which are attached to words or to sentences to express moods or aspects. In addition, there is considerable overlapping of function among Chinese words, just as in English the word “cut” can be used as a noun, a verb, or an adjective. The common belief that Chinese has no parts of speech is a gross exaggeration. Most words have only limited functions: *chih* (paper) is always a noun; *t'i* (kick), always a transitive verb; *tsao* (early), always an adverb or quality verb.

While the above sketch gives the main structural features of the Chinese language, it will be of interest to the general reader as well as the practical student to see how the formal features of an Occidental language like English would be translated into Chinese. In the first place, an English word corresponds in translation much more closely to the syntactical word in Chinese than to the monosyllabic root word: *ti-pan* (ground-board—floor), *huo-ch'ê* (fire-vehicle—train), *hsien-tsai* (appear-exist—now), *t'u-shu-kuan* (charts-books-institution—library). Chinese nouns are not distinguished by number, the notion of number being expressed, when necessary, by numerals or by words like “many” or “several.” There are no articles, but most nouns designating individual persons or things have specific numeratives or classifiers which must be attached to a preceding numeral or demonstrative: for example, *i-t'ou nu* (one head of cattle); *ch'ei-ko jên* (this piece man). Definiteness and indefiniteness are expressed by specific words, and there is a strong tendency to place words of definite references in the subject position and words of indefinite reference in the object position. *Shu hai mei k'an* means “The book has not yet been read,” but *hai mei k'an shu* means “(One) has not yet read (any) book.” Personal pronouns have no case or gender, *t'a* meaning “he,” “him,” “she,” “her,” or “it.” There are a few prepositions, such as the semilitary *yü* (at), but most spatial and temporal relations are expressed by substantive root words of location: *li yu ren* (room-inside has people—there are people in the room); *shan-shang tê shui* (hilltop's water—water on the hill).

Chinese verbs have neither tense nor voice, and notions of time or received action are expressed, when necessary, by adverbs or other explicit means. Complete action or change of state, whether in the past, present, or future, is expressed by the particle *lê*. Progressive action is expressed by the particle *chih* or *chê* (-ing), the adverb *chêng tsai* (right at), or the final particle *nê*. The verb *shih* (to be), is normally used before predicate nouns, as in the expression *wo shih jên* (I am a man), but it is not used before adjectives, since these are themselves verbs. Because the qualifier always precedes the qualified word, an adverbial clause always precedes the main clause, as in *yao-shih ni lai, wo chiu lai* (If you come, I then come—I shall come if you do).

Historical Development.—The preceding description covers the principal features of the Chinese language. In a country as large as China, however, there are many dialectal variations, and there have also been changes through the centuries. This is especially true of sound, less so of vocabulary (the use of words out of the stock of root words), least of all of grammatical structure.

In the period represented by Confucius (c.551–479 B.C.), the Chinese language possessed a rather rich system of consonants and vowels, and probably only three tones. There were four grades of initial consonants (for example, *p*, *p'*, *b*, *b'*, like the Sanskrit *p*, *ph*, *d*, *dh*) and a variety of consonant endings (*-m*, *-n*, *-ng*, *-p*, *-t*, *-k*, *-b*, *-d*, *-g*, *-r*), but no final semivowel. There were also occasional consonant clusters like *kl-* and *pl-*. Later, as we learn from a dictionary published in 601 A.D., and other sources, the four grades of consonants were reduced to three: *p*, *p'*, and *b'*. The final consonants *-b*, *-d*, *-g*, and *-r* were dropped, and final semivowels appeared, to form diphthongs with the main vowel. The number of tones increased to four. In the majority of the modern Chinese dialects there are usually only two grades of consonants (*p* and *p'*) and, as we have noted, three consonant endings (*-n*, *-ng*, and *-r*). The four tones of modern Chinese differ from those of ancient Chinese in that the old first tone has been subdivided into the modern first and second tones and the old fourth-tone words have been distributed among the other modern tones.

The monosyllables functioned more independently as words in ancient Chinese than they have in the language at later stages. Moreover, there are in the old texts traces of inflection, as in the use of *ngo* for “I” and *ngâ* for “me.” The cognate modern words, *wu* and *wo*, have no such distinction. In general, however, there has been remarkably little structural change in the Chinese language.

The chief dialects into which ancient Chinese has developed may be classified into nine groups: Cantonese, Kan-Hakka, Amoy-Swatow, Foochow, Wu (Kiangsu-Chekiang region), Hsiang (Hunan Province), and Northern, Southern, and South-western Mandarin. The first six groups, which are concentrated in the five or six provinces on or near the southeast coast, have preserved more features of the ancient pronunciation than the others. The last three groups, which cover three fourths of the area of China proper and two thirds of the entire population, are characterized by relative uniformity of pronunciation and vocabulary. For this reason, it is possible for a resident of Peking (Harbin), Manchuria, to understand a resident of Künming, Yunnan Province, without too much difficulty. Standard Chinese, variously called Mandarin or *kuo-yü* (national language), belongs to the Northern Mandarin group, and its standard of pronunciation is that of Peking.

A development of great cultural significance in the history of Chinese has been the growth of a literary language along with the spoken language. We have evidence that at least as early as the 9th century A.D., there were two divergent idioms, one quite similar to present day Mandarin, and the other like the writing of previous centuries. Through the centuries the spoken language, which was rarely written, changed more and more in pronunciation and vocabulary, whereas the written language, because all literate Chinese read a common body of literature, remained almost uniform. Such changes as have occurred in the written language have taken place throughout the country, that is, uniformly with respect to diction and composition, though not with respect to pronunciation. Hence every educated Chinese has one system of pronunciation, that of his present local dialect, whether Man-

darin or one of the other groups, but two idioms, his local spoken idiom and the literary idiom common to the whole country. The literary idiom does not merely exist on paper, but is learned through reading aloud, and the Chinese read and compose aloud or *sotto voce* to a greater extent than other peoples. Although literary Chinese is never spoken, it is an actual language or idiom (quite apart from the fact that there is a uniform system of writing for all the variant pronunciations).

In 1917, Hu Shih (1891—) and other scholars initiated a movement to have Chinese written in the spoken idiom rather than in the literary idiom. There already existed a small body of Mandarin literature, mostly in the form of novels. The movement was encouraged by the educational authorities, who ordered that the school curriculum through the sixth grade be taught in the spoken style of Mandarin, called *pai-hua* (plain talk). This step had two purposes. In the first place, it would be possible for two thirds of the country's children, those from the Mandarin-speaking provinces, to read and write in a close approximation to their mother tongue rather than in an additional literary idiom. Secondly, the remaining one third would learn the standard dialect, thereby helping to unify the spoken language. While the *pai-hua* movement made relatively slow progress from a quantitative point of view, by the 1930's it had succeeded in establishing the prestige of the spoken idiom. It had been most successful in literature and science, less so in the fields of business and government.

Writing.—The Chinese system of writing consists of characters representing the *tsü* or monosyllabic root words. Speech elements smaller than a syllable do not normally correspond to elements in the characters. According to the traditional system of classification, there are six categories of characters: pictographs, simple ideographs, compound ideographs, phonetic loans, phonetic compounds, and derivative characters. Examples of the first five categories are: (1) 山 (*shan*, mountain); (2) 二 (*êrh*, two); (3) 明 (*ming*, bright), consisting of the characters for "sun" and "moon"; (4) 無 (*wu*, have not), a pictograph for a word with the same sound meaning "dance," it being impossible to picture the idea of "have not"; and (5) 柿 (*shih*, persimmon), consisting of a significant part, 木 (tree), and a phonetic part, 市 (*shih*, market). The sixth class contains few members and is not important.

Although the characters have changed comparatively little in 2,000 years, the pronunciation of the language has altered considerably. When a modern Chinese reads a passage of Confucius or Lao-tzu, he reads words of his own present day dialect which are cognate with the words of the ancient language. Because the phonetic changes from ancient to modern Chinese have not always been parallel and regular, the phonetic parts of the phonetic compounds—a majority of all characters—do not always indicate the modern pronunciation of the compounded characters and in practice have to be learned individually.

There is only a rough correspondence between the spoken word and the written character. Because of the process of phonetic loans mentioned

above, a character often represents words which have the same sound but different meanings. For example, the character 未 represents two words: *wei* (not yet) and *wei* (the first double hour after noon). A much more important divergence between word and character has taken place because the number of characters has been increased to indicate extensions of meaning of what is linguistically the same word. Thus the word *yüan*, meaning "primary," "original," or "source," for which a single character, 元, was used in the ancient texts, has come to be written with three different characters—元, 原, and 源—for its three meanings. In this way, the number of characters used for most words in Chinese has multiplied to several times the number of the words. In a large dictionary there are about 40,000 or 50,000 characters, and the telegraph code book contains nearly 10,000. One kind of Chinese typewriter has 5,400; a list of characters for use in the first four grades of school has 2,741; and the basic list of Yen Yang-chu (James Y. C. Yen, 1894—) has 1,200. The number of root words in the speech of an illiterate adult is estimated at 2,500 to 3,000 *tsü*.

Characters are arranged in dictionaries according to sound or form. The oldest dictionaries grouped characters according to tones, rhymes (vowel and ending), and initial consonants, so that all characters with the same sound appeared under the same heading. Modern dictionaries which arrange characters by sound reverse the order: initials, finals, tone. A more frequently used system is the arrangement of the characters according to the 214 radicals or recurrent parts. These correspond roughly to the significant parts of phonetic compounds. The radicals are arranged in ascending order of number of strokes, and the characters under each of the radicals are arranged in ascending order of the number of the remaining strokes. In addition, a system of arrangement based on the four corners of the characters is often used in library catalogues.

Since it is difficult to learn large numbers of characters, various schemes of writing reform have been proposed and tested on a limited scale. In 1919 the Ministry of Education promulgated a set of 39 national phonetic letters (later revised to 40, then to 37) as an aid to the unification of the national language. Occidental missionaries have tried to use these letters as a system of phonetic writing. In 1928 the Chinese government adopted a system of national romanization as an alternative to the phonetic letters. Various technical and cultural difficulties, however, stand in the way of an alphabetic system of writing. Since the concise literary idiom based on the language of past ages, when there was a rich variety of sounds, is no longer completely intelligible to the ear when read with a modern pronunciation (as it always is), it is not intelligible to the eye when written with the modern Mandarin pronunciation. The use of an alphabetic system must therefore be limited to writing the spoken idiom. The adoption of such a system, its opponents argue, means a break with the past, as represented in the literary idiom. They also fear that if people wrote their dialects alphabetically, the unity of the written language would be destroyed. Those who favor alphabetic writing contend that its adoption would further

the vernacular literary movement and help to spread the knowledge of standard Mandarin.

Romanization and Pronunciation.—During and after World War II there was a marked increase of interest in the Chinese language among English-speaking peoples. Methods of teaching based on modern linguistic research have made the problem of learning to speak Chinese fluently a matter of one or two years, instead of five or ten. For the general reader who does not intend to learn the language, a knowledge at least of the Wade-Giles system of romanization, commonly employed in books written in English on Chinese subjects, is desirable. The English equivalents of the Chinese sounds of the letters in the Wade-Giles system of romanization are as follows:

a	father	i	police
ai	aisle	ih	vocalized
au	out		r
h(i), ch(ü)	jeer	k	goat
h(ih), ch(other vowels)		k'	coat
h'(i), ch'(ü)	dry	p	beak
h'(ih), ch'	cheer	p'	peak
(other vowels)	try	t	deem
ɛ	up, long-thened	t'	team
h	oh yeah	ts, tz	Windsor
i	eight	ts', tz'	it's hot
erh	err, Middle Western	u	rule
hs	she; German ich	u	French usine
		ü	buzz
			Other letters as in English

3. LITERATURE. In dealing briefly with a literature that extends back to approximately the 15th century B.C., our main concern will be with belles-lettres. Yet works of history, philosophy, allegory, and aphorism, especially of the early periods, are so closely woven into the roots of all later literature that they must be given due attention.

The conventional division of Chinese literature into four departments—canons, history, philosophy, and miscellany—is merely an outdated library science without direct bearing on our discussion. More relevant are the following age-old characteristics:

(1) Although in most dynasties the court was the center of literary fashion, folk creation was the important life-giving force of literary innovations. Foreign influence on poetry and fiction often took roots first in folk songs or folklore.

(2) The ancient Chinese had a rich mythology, but left no full-fledged epic poetry to portray its heroes and gods. Rather, they became idealized men of worldly moral deeds, celebrated in didactic prose.

(3) Pacifist spirit predominates. The Chinese word for literature, *wên*, is the exact antonym of militarism, *wu*.

(4) Romantic otherworldliness, passionate

pursuit of love, and tragic conflicts of will and fate are seldom carried far. Spirituality develops in the physical world and pervades it. Hence, faithful representation of simple mundane experiences and spontaneous expression of intuitively grasped natural beauty gain breadth and depth of meaning.

(5) The peculiar qualities of the Chinese language—the logographic writing and the determination of word meaning by exact tonal modulations—ally the literature closely with the fine arts and music. In poetry the monosyllabic written characters make it easy to achieve extremely neat patterns of meter and rhyme; and prose, in the classical style at least, often rises to the level of poetry. See also section on *Language*.

The Classical Age (c. 15th to 3d Centuries B.C.).—The earliest authenticated writings of the classical period of Chinese literature are inscriptions on bronze vessels and oracle bones, the most ancient of which date from about the 15th century B.C., during the Shang dynasty. They are remarkable for their calligraphy, simplicity, symbolism of intense religious devotion, accurate recording of dates and events, and occasional solemnly sonorous rhymes. The first real flowering of Chinese poetry is found in the *Book of Odes* (*Shih Ching*), produced between the 10th and 7th centuries B.C. Extant in the book are 305 poems—lyrical, ritual, satirical, and narrative—largely of folk creation, and closely associated with music. The poems are spontaneous, vivid, and realistic expressions of social life and customs. Metrical schemes vary, but tend to follow the four-word line, with frequent rhymes. These poems enchant us with word music from the hearts and souls of a people singing millenniums ago of their love, courtship, reverence, worship, despair, lamentations about bad times, and protests against tyranny and war. They ever remain living embodiments of natural objects lighted by vivified senses of man at poetry's dawn.

Four other works, chiefly products of the classical age, are grouped with it in a collection called the Five Canons or Classics. The *Book of Change* (*I Ching*) consists of a set of symbols and texts for divination, perhaps first formulated about the 11th century B.C., with later commentaries. It presents in abstract form the original Chinese conception of the dual forces which set the universe in motion. The *Book of Historical Documents* (*Shang Shu*), sometimes called the *Book of History* (*Shu Ching*), consists of decrees, counsels, and admonitions of ancient kings, princes, and ministers, and other semilegendary records, attributed to a period from the dawn of history to about the 7th century B.C. In solemn, didactic prose, it portrays the thought and action of great ancient Chinese, who, it was said, having struggled with nature and learned its secrets, set moral standards by personal example, formed benevolent governments, vindicated the people against tyrants, and so became prototypes of the ideal sage to inspire the philosophical and literary mind of later ages. The *Spring and Autumn Annals* (*Ch'un Ch'iu*), brief records of current events from 722 to 481 B.C., because of the meticulous choice of "correct terms" in their definitions, have influenced historiography and historicoliterary criticism. Finally, some ancient ritual codes and principles of government compiled about the 2d century B.C., together with a number of Confucian dissertations, constitute the

Book of Rites (Li Chi). The Five Canons, despite misinterpretations, interpolations, and forgeries, reveal the primary forms of ancient Chinese literature and mark the beginnings of the Chinese literary tradition.

Between the 6th and 5th centuries B.C., Chinese literature entered a new stage of development, marked by increasingly elaborate description, interesting anecdotes, suggestive observation, and illuminating critiques. Of the numerous schools of philosophy which emerged during this period, two, the Confucian and the Taoist, became leading sources of spiritual guidance for later generations. To the Confucianist, man's life on earth is all important, even the world of the dead being somehow an extension of this one. Heaven and earth, the original parents of all human kind, are benevolent. Man can achieve the supreme good through aspiring toward perfecting pragmatic virtues in human relationships. The Confucianist, while acquiescing in man's fate as directed by some invisible power, seeks not to know the nature of that power beyond this world. Man's highest standard is set in humanity itself, symbolized by the ideal human sage, the perfection of the best of human nature. Much of Confucian-influenced Chinese literature is enlivened by a humanistic this-worldliness, and the most creative Chinese writers claim kinship with the classical tradition.

Confucius (c. 551–479 B.C.) himself is believed to have written little. Even the traditional claim that he edited some of the Canons is now questioned. We are certain only that his aphorisms and short discourses were recorded by his disciples in the *Analects (Lun-yü)*. Two dissertations by his followers—*The Great Learning (Ta-hsiieh)* and the *Doctrine of the Mean (Chung-yung)*—expound his philosophy in a better organized form.

The Taoist school, supposedly founded by the philosopher Lao-tzu (-tse, c.604–531 B.C.), represents a reaction against Confucianism. The canon of this school, *The Canon of the Way and of Virtue (Tao-tê ching)*, shows that it emerged no earlier than the late 5th century B.C. According to Taoist thought, there is above the physical universe a higher power, the way or *tao*. It is not a personified god, but a transcendental force above all existence and nonexistence—the absolute—which is manifest in the perfect natural state of things, the highest which man may hope to attain—the supreme good. To the Taoist all discriminations are artificial; all commonly accepted virtues pre-suppose prevalent evils. "Not until the Sage is forever dead can the Bandit be completely put out. . . ." Strong and pervasive Taoistic influence on Chinese literature has nurtured the spirit of freedom from all conventions, developing the poet's faculty for self-abandonment and keen insight into nature.

Among the philosophers of the two leading schools, Mencius (372?–?289 B.C.), the Confucian protagonist, left behind eloquent passages of oratory, and Chuang-tzu (-chou, fl. 4th to 3d centuries B.C.) wrote unsurpassed Taoist allegorical essays which form an inexhaustible source of subtle metaphor and simile. Other philosophic schools of the period—the Moists, or followers of Mo Ti (fl. 5th–4th centuries B.C.), who preached universal love, the Legalists, and the Logicians—were later overshadowed by the two great schools or lost in practical politics.

As the classical age drew to a close amid

incessant wars, sensitive men felt a keen *Weltschmerz*. Late in the 4th century B.C. appeared richly imaginative and colorful works of pure sentiment by poets of great individuality, who cultivated their art consciously through the best use of words, independent of music. Most of this new poetry was written in the Yangtze River area, the picturesque southern region of abundant flora, fantastic landscape, and emotionalism. The earliest works of this type are attributed to Ch'ü Yüan (c.343–?289 B.C.), once a minister and then an exile of the Ch'u state. His chief follower and imitator was Sung Yü (296–?240 B.C.), also of Ch'u: hence the name Ch'u rhapsody or elegy (*Ch'u tz'ü*) is applied to this style. A lengthy prose-verse mixture, with interwoven dramatic dialogue, fanciful narratives and descriptions, and soaring lyrics, it has maintained lasting influence on later imaginative literature. Sung Yü and the northern philosopher Hsün-tse (c.300–235 B.C.) also called their writings after this style *fu* (exhibitory essay), which was to develop into a very important genre in the Han age.

The Middle Epoch (2d Century B.C.–7th Century A.D.).—At the beginning of this literary period, which coincides with the major part of the Chinese medieval period, the country entered an era of national consolidation, expansion, and prosperity. The short-lived Ch'in dynasty had unified China and laid the foundations for the enormous development of the Han empire. The flourishing literature of the Han dynasty combined court refinement with robust folk elements. Its growth was nourished and stimulated through foreign contacts—with the Hsiung-nu in the north, the Tungus in the northeast, the Pacific coastal and island tribes, and the countries of central Asia. Foreign melodies and musical instruments were introduced, and exotic customs and landscapes were portrayed and discussed with growing inspiration. Now the *fu*, as court literature reflecting the new vision and material splendor of the age, unfolded at its best a panorama of rich colors and gorgeous imagery. Its greatest master was Ssü-ma Hsiang-ju (179–117 B.C.). Other distinguished writers of the *fu* were Mei Shêng (d. 140 B.C.), Yang Hsiung (53 B.C.–18 A.D.), Pan Ku (32–92 A.D.), and Chang Heng (78–139 A.D.).

As the *fu* developed, creativeness gradually gave way to stereotyped floridity. Not until the 11th century, the age of great prose, did this form, liberated from slavish imitation and artificial metrical restrictions, become a lucid but impassioned prose poem. Yet beginning with the Earlier Han dynasty lyric and narrative poetry derived directly from folk literature developed with fresh vigor. Many works of this type, often anonymous, are great poetry, comparable in directness, spontaneity, and profundity to the *Book of Odes*. Collected, edited, and sung in the Imperial Conservatory, they were soon recognized as an influential poetic genre, called the Imperial Conservatory or *yüeh-fu* style. Their metrical schemes were at first as varied as the musical forms of the age, but later a tendency toward regularity gradually emerged. Out of a sound pattern with five characters to a line came the *ku shih* (old-style poetry).

Although both folk and more sophisticated works in the Imperial Conservatory tradition flourished in earlier Han times, most of those still extant date from Later Han dynasty. Most re-

markable of the anonymous works are the *Nineteen Old Poems* and *The Wife of a Prefect Clerk*, a narrative poem of 1,800 words in 360 lines. The latter tells the story of the devoted love of a husband and wife, frustrated by a domineering mother, and ending in tragedy. Among the many authors were the poetess Pan Chao and the poet Fu Yi (both of the 1st century A.D.), Chang Heng, and Ts'ai Yung (133-192 A.D.). Much of Han poetry was tinged with Confucian moralism or Taoist mysticism, but it excelled in the objective description of social life and customs and in a deep understanding of the sorrows and joys of humble people. The love poems dealt more often with man-and-wife relationships than with intrigue or romantic courtship. In general, Han poetry represents the healthy growth of the Chinese people and of their old, stable society.

While literary forms like the *fu*, the *yüeh-fu*, and the *ku shih* grew so luxuriantly that belles-lettres began to form a major category of their own and individual genius shone more brilliantly in this field than ever before, we should not fail to mention the writings of the great Han historian, Ssü-ma Ch'ien (145-?87 B.C.). In the classical age history had consisted of the fragmentary record of events or of a mixture of anecdote, oratorical harangue, and short didactic discourse. Now, with Ssü-ma Ch'ien's *Historical Memoirs* (*Shih Chi*), it developed into lucid, systematic narrative. The traditional anecdotes were objectively examined, and historic figures became living personalities. In his masterly prose, Ssü-ma Ch'ien depicts representatives of the lower social strata as well as kings and emperors. The *Historical Memoirs* have been handed down as the first comprehensive Chinese history and the prototype of subsequent biography. Ssü-ma Ch'ien's follower and imitator, Pan Ku, in his *The History of the Former Han Dynasty*, set an example for later dynastic historians with his erudition and thorough treatment of all cultural subjects.

Three other aspects of Han intellectual life have had a lasting influence on Chinese literature:

(1) The rediscovery in fragmentary form of ancient canons, lost in wars and destruction, engaged many scholars in the tasks of philological research and textual reconstruction. Excellent results were obtained in such works as the *Etymological Dictionary* (*Shuo-wên*) of Hsü Shên (d. c.120 A.D.), and the *Survey of Dialects* (*Fang-yen*), attributed to Yang Hsiung. But fabrications and distortions of the ancient texts, largely by Liu Hsin (50 B.C.?-23 A.D.) and his contemporaries, perpetuated many misconceptions and superstitions about ancient China.

(2) The elevation of Confucianism to the rank of a state philosophy marked the beginning of its manipulation by the rulers of successive dynasties, who evolved dogmatic orthodoxies from it to suit their purposes, obscuring its humanistic philosophy with religious mysticism.

(3) Indian Buddhism began to compete with Taoism in popularity, giving rise to many superstitious cults and enriching Chinese folklore. Such Indian ideas as cycles in future worlds and nirvana, introduced in Later Han, were not as yet thoroughly digested. Mythical thinking and fanatic faith prevailed in influential circles. The crisis in philosophic thinking provoked Wang Ch'ung (27-97 A.D.) to write his *Animadver-*

sions (*Lun Hêng*), in which he analyzed and evaluated the spirit of the age. Championing literary creativeness and vigorously attacking bigotry and pedantry, he produced one of the most important contributions to Chinese philosophical and literary criticism.

With the decline of the Han dynasty, the second literary cycle began to wane. Nevertheless, the strife-torn times were brightened by a flash of literary creation. The leading figures were Ts'ao Chih (192-232 A.D.) and the Seven Greats of the Chien-an period (196-220), and Emperor Wei Wên Ti (Ts'ao P'ei, r. 220-226), first of the Wei dynasty, the first successful experimenter with a new poetic pattern of seven characters to a line. In this brief but memorable period all the literary forms popular since the Earlier Han dynasty reached new heights. Its writings were individual and tender, rich in true feeling and vigorous expression. Some of them, voicing the spirit of the age, show emotional depth and spiritual exaltation. The Wei dynasty (220-265 A.D.), one of the Three Kingdoms, was supplanted by the Tsin (Chin, 265-420 A.D.), which in the year 317 was pressed southward by barbarian tribes. In its new southern center at Chienkang (near modern Nanking), the capital of the defunct Wu dynasty (222-280 A.D.), the Tsin and four succeeding dynasties maintained a precarious existence under constant threats from the north. Here in the Yangtze Valley, through the Six Dynasties period, ending in 589 A.D., a picturesque, fanciful, sentimental, and highly artificial literature developed, stamping with its characteristic decadence the decline of a literary cycle.

Contemporaneously, north China, occupied by barbarian tribes, produced fairly little creative literature. Yet there were some charming folk verses, and the warlike spirit of the nomadic peoples occasionally burst into heroic song. The northern landscape, seen afresh under foreign rule, was sometimes depicted with barbaric beauty, sometimes with deep melancholy. These sporadic writings enriched Chinese literature.

In the south, the efforts of the literati to achieve painstakingly cultivated workmanship and mature literary criticism prepared the way for the Chinese literary renaissance. In both prose and poetry there was an extreme development of line-for-line and word-for-word parallelism. The parallel prose (*p'ien wên*) is unique, with virtues and vices of which only the Chinese language is capable. The standardization of the four tones of the language, which contributed much to later formalism, must also be credited to the early part of this period. Great literary craftsmen wrote valuable treatises on the art of writing, such as the *Essay on Literature* (*Wên Fu*) by Lu Chi (261-303). Hsiao T'ung (501-531) made the first comprehensive anthology of Chinese creative literature, *Literary Selections* (*Wên-hsiian*), in which he meticulously classified 38 separate forms and further subdivisions. And against the background of an artificial age, the critic Liu Hsieh (fl. late 5th-early 6th centuries) produced his *Literary Mind* (*Wên-hsin tiao-lung*, c.480), a penetrating re-evaluation of the past and a sober criticism of the contemporary scene. In 50 illuminating chapters he examined and analyzed virtually all that there was to be known about literary principles, forms, values, and personalities. Of the same type, but more specialized, was the *Classification of Poets* (*Shih*

P'in), a thorough evaluation of the poets of all periods, by Chung Hung, who lived about the same time. Both works, deeply critical of contemporary writing, heralded a more wholesome age.

A few creative writers, too, had superb achievement. In a painful period of disunion and chaos, the famous Seven Worthies of the Bamboo Grove produced memorable poetry of escape. Their prodigious wine drinking, fantasies about the cosmos, and spiritual escapades were celebrated in inspired verse. Other representative poets were Hsieh Ling-yün (385-433) and Yen Yen-chih (384-456), whose elaborately decorated and cleverly chiseled works portray nature with effects resembling those of pre-Raphaelite painting. Also distinguished was Pao Chao (c.400-466), who wrote poetry with a feeling and expression rare among his contemporaries. But the uniquely great poet of the period was T'ao Ch'ien (T'ao Yuan-ming, 372-427), the Renowned Recluse, who pictured a profound harmony between nature and life, fate and human will, in a flow of effortless and placid verse which was later to be often emulated but never equaled.

The Renaissance and Neoclassicism (7th to 10th Centuries A.D.).—When the brief Sui dynasty, which reunited China, was succeeded by the T'ang, literature entered a new cycle in a splendid age of Chinese history, an age worthily called the renaissance. It sought to realize old values in their proper perspective; benefited, after 300 years of foreign occupation in the north, from the assimilation of many peoples; and experienced an unprecedented blending of Confucianism, Buddhism, and Taoism. It was an age of tolerance and spiritual adventure, of integration and creation. Literature had never been so strongly nor so deliberately stimulated. Since poetry was regarded as an expression of the best minds, verse making was made a requirement in the civil service examinations. Yet it was not merely a means of winning court favor. From the ranks of both court and folk poets arose humanists who produced sharper, more varied, and more numerous pictures of society and of individuals than had the writers of any earlier period. No part of human life was too trivial to be left unsung. The great T'ang poets commanded a wide audience. Not only the court and the intelligentsia, but songsong girls, public entertainers, and the barely literate—all showed a discriminating interest in contemporary verse.

T'ang Poetry.—The poetry of this age developed in four stages: early (c.620-710); heyday (c.710-780); middle (c.780-830); and late (c.830-906).

The Early Period: This period was marked by a demand for a return to classical simplicity and clarity. Although the vogue of artificiality inherited from the preceding age persisted, it was infused with new life by a rising generation of poets. Two favorite courtiers of Emperor Chung Tsung (r. 684; 705-710)—Shên Ch'üan-ch'ü (d. c.713) and Sung Chih-wên (d. c.710)—extracted from the essence of technical poetic theories a form called *lü shih* (regular poetry), which was to develop into one of the finest T'ang types. Although the four-line stanza could be infinitely multiplied to make a *p'ai lü* (extended form), eight lines were the norm, and all had to be of equal length, with five or seven characters. The middle four lines were always strictly parallel couplets with contrasting tones; the other lines

were comparatively free. This form was equally suited to the artificer and to the serious poet who preferred a formal structure. The outstanding poet of the early period was Ch'ên Tzū-ang (656-698), who was recognized by the master poets of the heyday as their only pioneer.

The Heyday of T'ang: In this period T'ang poetry rose to its zenith. Its ascent was prepared by increasing social development and prosperity in China, and accelerated by conflict and suffering. Emperor Hsüan Tsung (Ming Huang, r. 713-756 A.D.), with whom this period began, was a great patron of poetry and the arts during the internally peaceful early years of his reign. There was, however, continuous fighting on the frontiers of the widely expanded T'ang empire and in later years the emperor's extravagance and favoritism precipitated a rebellion against him.

The poets of this period identified themselves with its tragedies and its felicities. The most distinguished were Li Po (701/705-762) and Tu Fu (712-770), who are commonly recognized as the master spirits of Chinese poetry. Both reacted against the immediate past and claimed kinship with the classics, but they were entirely different in temperament. Tu Fu stood for Confucian this-worldliness. He is the great secular poet whose works are realistic etchings of a tormented humanity. In them exquisite scenery and lovely human forms appear in relief against a background of mundane life. Li Po had an affinity for Taoist transcendental naturalism. In his poems magnificent landscape, female beauty, and earthly love are transcended and mirrored in the eternal spirit of the cosmos. The finest works of Tu Fu were written in *lü shih* style, which best suited his exactness and precision of expression. Li Po was most successful in his freely improvised *ku shih* and in the *chieh chu* (curtailed poem), a short song form popular in the T'ang age which was restricted to four even lines but was capable of suggesting infinite overtones.

Among the many other celebrated poets of the T'ang heyday were Wang Wei (699-759), the painter, famous for evoking "poetry in his painting and painting in his poetry"; Meng Hao-jan (689-740), who wrote some of the period's tenderest lyrical verses; Wang Ch'ang-ling (c.700-765), master of the *chieh chü*; and Ts'ên Shên (715-770) and Kao Shih (c.700-765), who left memorable verses about battles and expeditions on the rugged frontiers.

The Middle Period: During the middle period pacification of internal turmoil and resistance to invasion were alternately successful and frustrated. In this Indian summer of the T'ang dynasty poetry developed in a new way with the emergence of two great figures—Han Yü (768-824) and Po Chü-i (772-846)—representing two new schools. Han Yü, celebrated chiefly as a leading advocate of neoclassical prose and a champion of Confucianism, was also an innovator in poetry. His works, which are sometimes marred by argumentative tirades and moral preaching, contain lines of strange beauty, with grotesque images, dissonant tones, and freakish rhymes. Occasionally the ugly and the horrible hold a fascination for him. He influenced Mên Chiao (751-814) and Chia Tao (788-843), both of whom produced perfectly chiseled lines of great originality, and Chang Chi (765-783) who wrote mainly of feminine heartbreak and social injustice. The most extraordinary talent

among Han Yü's friends and followers was that of Li Ho (790-816), whose imaginative power in weaving together the most diverse subjects, and superb sensibility for word music and vivid imagery, earned him the name of ghost genius.

Po Chü-i, who led the other school of this period, had a style so simple and clear that it came close to the language of the people. His famous long poems are actually touching romances in melodious speech. Despite the apparent easy grace and intimate charm of his verses on almost every detail and triviality of daily life, Po was a poet of very serious purpose. With his vernacular diction and commonplace rhymes, he spoke for ordinary people in a way they could understand. Closely associated with him were Yüan Chên (779-831) and Liu Yü-hsi (772-842).

Standing alone between the two schools of the middle period was Liu Tsung-yüan (773-819), the celebrated exile, whose poems about strange landscapes and tranquil natural scenery attained an austerity and spirituality reflecting the strong influence of Buddhist philosophy.

The Late Period: Toward the end of T'ang the imperial court was crumbling and signs of disintegration appeared everywhere. Yet this sunset of a glorious age of poetry was not without splendor. The three leading poets of the period were Tu Mu (803-852), known for his heroic style, and Li Shang-yin (813-858) and Wên T'ing-yün (fl. mid-9th century), whose works were distinguished by their elegance and colorful imagery. The artificiality of their poems, however, was a sign of approaching decadence.

T'ang Prose.—Essays and fiction showed great distinction in the T'ang age. Han Yü and Liu Tsung-yüan, the great middle T'ang poets, were recognized leaders in neoclassical prose writing. Both opposed the florid parallelism which had been in vogue for 500 years. While Han, an ardent Confucianist, wrote vigorous polemic and expository works, Liu, more detached, drew sharply outlined portraits of persons and crystal-clear landscape sketches. The two men perfected many forms of the modern Chinese essay.

The first real fiction was also developed in the T'ang dynasty. Earlier works had been mere fables or naive tales; in the T'ang short stories intriguing plots and vivid characterizations were developed. Among these stories, which were modestly called *ch'uan ch'i* (curious traditions), are gems comparable to the best Western medieval romances. The two most important writers were Yüan Chên, the poet, and Li Kung-tso (770-c.850). Love, chivalry, social satire, fanciful ideas about Buddhist visions, and Taoist mystical experiences were among their favorite subjects. These stories retained their influence on later fiction and drama, continuing to add spice and color to popular beliefs. But their form and content attest the creativeness of the T'ang age, which lifted superstition to the level of imaginative literature.

Contemporary literary criticism is found mainly in the casual but illuminating remarks of the poets and prose writers in their conversations, letters, and private journals. During the declining years of the age, which were marked by a belief in art for art's sake, there developed a vogue for gleaning famous lines of great masters in handbooks called *shih chü i'u* (samples of poetic patterns). Some of the editors of these books showed sound critical sense, but the great critic of the age was Ssü-k'ung T'u (837-908).

In the twilight of T'ang, as if for its swan song, he wrote in superb, impressionistic verse, with the choicest metaphors and similes, a book of criticism called *Poetic Characteristics* (*Shih P'in*), in which he presented the 24 qualities to be desired in poetry. Although the author did not intend to be dogmatic, his work, because of its trenchant aphorisms and melodious style, became a kind of sutra for Chinese poets.

The Five Dynasties.—In the courts of some of the kingdoms into which the country was divided after the fall of the T'ang dynasty, a few tender and sensitive writers composed superb songs of deep nostalgic pathos in the *ts'ü* form, which was to rise into an important genre in the next age.

From the Age of Reason to the Rise of the Drama and the Novel (10th Century to 1900).

—The end of adventurous expansion and the achievement of internal unity ushered in an age of inner reconstruction and philosophical contemplation. The Sung dynasty was an age of masterly prose. In this period the ideas of Confucianism, Taoism, and Buddhism, which had stirred men's hearts in the lyrical T'ang age, were mullied over and subjected to scientific scrutiny. Poetic forms perfected in T'ang now became conventional, but the rarefied music of a form of pure poetry, the *ts'ü*, developed since the decadence of the previous age, came into full flower. And the Sung dynasty must be credited with pioneer novels and plays in which literary craftsmanship contracted a new union with the vernacular, to produce a flowering of creative works in both fields through the Yüan, Ming, and Ch'ing dynasties—a rising tide of vernacular literature which was to culminate in the sweeping vernacular movement of the 20th century.

Sung Prose.—Foremost of the Sung prose writers was Ou-yang Hsiu (1007-1072), a classicist who reacted against artificial parallelism and floridity and favored a return to simplicity and directness. His major accomplishment lay in making prose serve the uses of his time. The flowing style of his political treatises, philosophical dissertations, and essays had a flexibility of rhythm and a clarity of structure unattainable in poetry. His followers included Wang An-shih (1021-1086), the great political reformer, distinguished for his wit and penetrating observation, and the poet Su Shih (Su Tung-p'o, 1036-1101), whose prose writings were brilliantly variegated. Like his master, Su Shih left unsurpassed prose poems. His father, Su Hsün (1009-1066), his brother, Su Chê (1039-1112), and their contemporary, Tsêng Kung (1019-1083), all achieved great distinction. These six, with Han Yü and Liu Tsung-yüan of the T'ang dynasty, are known to Chinese school-boys as the Eight Masters of T'ang and Sung. Prose writers of the Yüan, Ming, and Ch'ing dynasties imitated or criticized their classical style but never surpassed it.

Rationalist philosophers of the Sung dynasty expressed in placid and deliberative prose their ideas of the order of the universe and their theories of knowledge. The commentaries and discourses of Chu Hsi (1130-1200), Lu Chiu-yüan (1139-1193), and others, written in the plainest vernacular, are memorable contributions to lucidity and naturalness of informal style.

Sung Ts'ü Poetry.—The development of the *ts'ü* is another instance of the close relationship between folk and polite literature. It first emerged during the T'ang dynasty as a group of

who gained national recognition was Chou Shu-jen (pen name Lu-hsün, 1881–1936). His poignant satirical novelettes, short stories, and essays brought him to prominence as the most influential critic of modern Chinese society. Hsü Chih-mo (1895–1931) was perhaps the first of the modern Chinese poets who successfully employed the contemporary vernacular to create new poetic forms. Kuo Mo-jo (1891–), novelist, playwright, and poet, very influential since the 1920's, has moved from Goethean romanticism to materialistic historicism.

In the 1930's and 1940's, before and during the Sino-Japanese War, plays and novels characterized by social consciousness and faithful realism were written in increasing numbers. The plays of Wan Chia-pao (pen name Ts'ao Yü, 1909–), which have been translated into several foreign languages, won him acclaim as the most important contemporary dramatist through his mastery of rich and fluent expression in the vernacular, and his penetrating observations of Chinese society in transition.

Bibliography.—GENERAL: Alexander Wylie's *Notes on Chinese Literature* (Shanghai and London 1867), though it needs to be revised, is well documented and generally informative. H. A. Giles, *A History of Chinese Literature*, is so far the first and only book in English claiming such a name, but is very superficial and inaccurate. A more recent work, in German, is Richard Wilhelm, *Die Chinesische Literatur* (Wildpark-Potsdam 1926). Among the most useful works in Chinese are Cheng Chên-to, *History of Chinese Literature*, 4 vols. (Shanghai 1930); and Tseng Yi, *History of Chinese Literature* (Shanghai 1930). On literary prose style see George Margouliès, "Evolution de la Prose Artistique Chinoise" in *Chinacyplopaedia*, sect. 4, vol. 6a (Munich 1929).

4. DRAMA. In the traditional Chinese theater singing is at least as important as acting. The Chinese refer in ordinary conversation to the drama as either *chü* (song) or *chi* (play), their conception of the art standing in significant contrast to the Western conception of drama as action.

Chinese drama can be traced back to the enchantments practiced by the ancient seers. In the Shang dynasty the *hsi* (sorcerer) and *wu* (sorceress), impersonating deified ancestors and gods, performed ceremonial songs and dances to propitiate the gods and spirits, invoking them to drive out pestilence, send abundant crops, and effect other miracles. The spectators at these performances were moved to join in the dancing. Out of these religious rites and folk dances arose a group of performers and musicians—brothers, historically, to the Chinese acting profession of modern times—employed by the court for the amusement of the emperors and the nobility.

The activity of the court entertainers reached its height in the Han dynasty, when clowns, wrestlers, acrobats, singing girls, and musicians, disguised as gods, fairies, warriors, tigers, leopards, bears, dragons, white elephants, divine turtles, and gigantic birds, enacted mythological stories before Emperor Wu (Wu Ti, r. 140–87 B.C.) and foreign tribute bearers from the western regions.

Formative Period of the Chinese Drama.—Because of the invasion of China by western tribes the music and dance of central Asia had a distinct influence on performances during the period of the Northern and Southern dynasties, as is seen in the warrior dance *Mask of the Duke of Lan Lin*, the revenge dance *Tiger*, and the comic dance *Drunkard's Wife*.

In the T'ang dynasty, Emperor Hsüan Tsung (Ming Huang, r. 713–756 A.D.) showed his in-

terest in the theater by founding at Changan (now Sian) the Pear Orchard, a place for training actors, musicians, and dancers. During the same dynasty there arose a new type of short comic sketch in dialogue form, called *ts'an chün hsi*, using two actors, the *ts'an chün* (leading player) and the *ts'ang hu* (supporting player). These comic pieces, like the other singing and dancing media of the period, had little story interest. They were satires in disguise, sustained by the wit and humor of talented actors and sometimes interlarded with timely political thrusts. The satire was not without hazard, since players were liable to punishment if their allusions to current events incurred the displeasure of royal patrons.

Under the Sung dynasty, with the rising influence of professional story tellers, the *ts'an chün hsi*, by that time known as *tsa chü* or *tsa hsi* (miscellaneous play), gradually shed its satirical and bantering quality and adopted story form. The various stories in a *tsa chü* performance were episodic and unrelated to one another, but the form became more complicated, with four principal characters and two subordinate characters. The dancing and singing which accompanied the performance became essential features of the Chinese legitimate theater. This simple type of *tsa chü* was the forerunner of the theater of the southern school, which flourished in both Hangchow and Yungkia (Wenchow). Records of the 13th century list titles of 280 *tsa chü* plays of the Southern Sung dynasty.

Yüan Drama.—After a period of incubation in northern China under the alien Chin dynasty, there arose during the Yüan dynasty the theater of the northern school, which represented a great advance over the *tsa chü*. Prosperity and peace created an unprecedented demand for the theater. Although the arts in general were ignored by the Mongol rulers, the theater, being responsive to a less cultivated but wider public than other art media, became the most vital literary expression of the time. When the Mongols abolished the civil service examinations, many Chinese scholars, for want of a better means of self-expression, turned to writing for the theater. By this time the drama of the northern school had evolved into its mature form, with four acts, a prologue, an epilogue, and an interlude for the exposition of a full-length story. In the hands of the dramatic talent of the day, action held the stage in place of narration, dialogue became dramatic and colorful, and metrical forms were much more varied.

The age of Yüan was unrivaled in its abundance of excellent plays. Among the best known are *The Sorrows of Han*, by Ma Chih-yüan; *The Sufferings of Tou-E*, by Kuan Han-ch'ing; *The Slave of the Treasure*, Chinese counterpart of Molière's *L'Avare*; *The Orphan of the Chao Family*, a tragedy distinguished by sublimity of conception and character; and *The Romance of the Western Chamber* (*Hsi-hsiang chi*), a romantic play of youthful love, written with rare beauty and inimitable literary flourish by Wang Shih-fu. These plays have been published in various languages, the earliest translation being Voltaire's adaptation of *The Orphan of the Chao Family*, which he called *L'Orphelin de la Chine*. The Yüan play which has been performed most frequently in Europe and the United States is *The Chalk Circle*, by Li Sing-tao.

At the end of the Yüan dynasty, as the theater

of the northern school began to decline, Kao Ming (courtesy name Kao Tsê-ch'eng, fl. mid-14th century), the earliest scholar of the theater of the new southern school, wrote his immortal play, *The Story of the Lute* (*P'i-p'a chi*), a complicated 42-act (in some versions, 24-act) development of the theme of filial piety, depicting the life of Chao Wu-liang, the idealized daughter-in-law of a scholar's family. In 1945 this play was presented in a form considerably shortened and mildly adapted in the New York musical success, *Lute Song*.

Drama in the Ming and Ch'ing Dynasties.—In the Ming dynasty, Wei Liang-fu (fl. mid-16th century), a musical genius of the south, introduced the epoch-making *k'un-ch'ü* school of singing. It became at once admired and influential and gradually forced the northern school theater of the Yüan period out of existence. During the ascendancy of the *k'un-ch'ü* school, T'ang Hsien-tsu (Tang Shien-chu, 1550–1617), one of its great masters, wrote his five romantic plays, of which *Peony Pavilion* (*Mu-tan t'ing*), in 55 acts, is the best example of his exuberant imagination and of his aptitude for portraiture and literary embellishment. Among the writers who tried to emulate his writing, and to excel him in metrical harmony, was Yüan Ta-ch'eng (d. 1645), a high official of the declining Ming dynasty. His best work was the play, *The Swallow as Go-between*, the love story of a singsong girl. In the Ming period the theater of the southern school reached its zenith. More than 100 of its plays survive.

The *k'un-ch'ü* school of singing continued to hold an indisputable position among numerous Chinese theater troupes during the first 150 years of the Ch'ing dynasty. Authors who professed allegiance to the Ming dynasty rather than to the foreign Ch'ing dynasty gave vent to their repressed sentiments in dramatic form. The most notable works of this period are *The Palace of Eternal Life* (*The Immortal Palace*, *Ch'ang-shêng tien*), by Hung Shêng (1646?–1704), a play based on the tragic love of Emperor Hsüan Tsung and his mistress Yang Kuei-fei; and *The Peach Blossom Fan* (*T'ao-hua shan*), by K'ung Shang-jên (1648–1718), on the theme of love and patriotism—a dirge among the ruins of the fallen dynasty. The period also saw the first attempt by a Chinese scholar to study dramatic construction, in an essay called *Casual Talks in Idle Hours* (*Hsien-ch'ing ou-chi*), by Li Yü (1611?–1680). In general, Ch'ing drama compares favorably in quality with that of the Ming dynasty.

After a short period of imperial patronage at the court of Emperor Ch'ien Lung (r. 1736–1794), the theater of the *k'un-ch'ü* school began to fall out of public favor because of its overelaborate poetic language and excessive refinement. Out of the melting pot of many theater troupes the *p'i-huang* school of the theater emerged to take the fancy of the common people. Its plays, still cherished as the most popular form of entertainment in China, are rarely of literary value; yet they have attracted a number of accomplished actors, greatest among whom is Mei Lan-fang (1894–).

Chinese Drama, Ancient and Modern.—Dramatic writing, an art long despised and neglected, had a late growth in China. The literati, who took to writing for the theater as a last resort, did not deign to learn the craftsmanship required by the form, but merely exploited it as a

vehicle for the exhibition of their literary achievements and imaginative ingenuity. At its best this kind of dramatic writing contains scenes of true sentiment, rich in poetic beauty and dramatic at fleeting moments. Yet, with few exceptions, Chinese plays of the old school are not well constructed. Victims of overattention to poetic justice, neglect of the logic of character, and indulgence in long-winded narrative, they lack the balance demanded by Western dramatic standards. Nevertheless, a study of the techniques used in producing these plays shows that, while generally lacking in realism, they can soar into flights of unhampered imagination and impart a feeling of pure theater.

The old Chinese theater is an art based on music. It combines singing, dancing, acrobatics, pantomime, and highly stylized acting. To appreciate its grace and beauty, and its sense of theatrical truth, one must bear in mind the fundamental conception of the Chinese playgoer that the theater is at best an illusion of life, to be evoked by the suggestiveness of acting and music and by the imagination of the spectator. The Chinese stage is almost as bare as the Elizabethan stage. It has a protruding square platform with no scenery and no curtain, and is faced on three sides by the audience. In the center hangs a decorative backdrop with openings at right and left for entrance and exit. The orchestra, which sits on the right side, is conducted by the player of the small drum, the sounds of which accentuate, with meticulous precision, every movement of the actors. Usually the orchestra comprises a "civil" part, with a Chinese violin, a flute, a Chinese moon guitar, and a Chinese cornet; and a "military" part, consisting of a big drum, a big gong, a small gong, and cymbals. The property man, who sets up the chairs, tables, kneeling cushions, and other simple properties, is never obtrusive and, so far as the audience is concerned, scarcely exists. The acting is entirely conventional. But its patterns seem beautiful and convincing when they are enlivened by the well-disciplined art of accomplished actors. The character parts, also conventional, are divided roughly into four major types of roles: the *shêng*, or male characters; the *tan*, or female characters; the *ching*, or characters with painted faces; and the *ch'ou*, or comedian. Until the revolution of 1911, all these characters were impersonated by men. With an oar standing for a boat, a whip for a horse, a table for a hill, a flag with the picture of wheels for a cart, and a painted cloth for a city wall, the genius of the Chinese theater succeeded in presenting, in its every aspect, the many-sided life of old China.

Modern Chinese drama has broken away from the traditions of the classic Chinese theater. Differing from the old in both form and spirit, it represents a revolution in dramatic technique. About 1900 politically conscious intellectuals, in an effort to depose the Manchu regime and to modernize their country, turned to the Western theater for inspiration and support. A great number of Western plays, including those of Henrik Ibsen, George Bernard Shaw, Anton Chekhov, and Eugene O'Neill, as well as the classics of every age, were translated, and some of them performed. Borrowing Western techniques of playwriting and production, talented dramatists and directors initiated a new theater, called *hua chi* (spoken drama), as distinguished from the old school of music drama. A drama of social

significance, its topical themes and varied production techniques have won the approval of the modern Chinese public. The new theater, alert to the impress of reality, reflects the life and thought of the people of China in their own everyday speech, in striking contrast to the classical verse of the old theater, with its stories of scholars, warriors, and kings. The new theater endeavors to be modern in form, yet distinctly Chinese in content. *Hua chi* occupies an unprecedented position in modern Chinese literature, exerting a far-reaching influence over the common people in their adjustment to the contemporary world. See also DRAMA; ORIENTAL THEATER.

Dramatist and Teacher

5. MUSIC. To understand Chinese music we should know something of its history, of the theories upon which it has been based, of the practices arising from the application of these theories, of the major Chinese musical instruments, of the various systems of notation, and of the influence of the language upon musical development.

Historical Development.—According to Chinese historical records, Chinese music can be traced back more than 4,000 years. Through the centuries, that music has been based on the Chinese standard pitch, called *huang chung* (literally, yellow bell). The ancient Chinese believed that the production of sound, as one of the elements of the cosmos, had much to do with the harmony of the universe. Other elements, such as time, space, and matter, were beyond the control of man, but he could create sound. By the sound he created he either strengthened the welfare of the nation or endangered it. For this reason, one of the most important duties of the first emperors of new dynasties was to regain the true pitch of *huang chung*. The exact pitch of *huang chung* is still a mystery, since measurements varied from one dynasty to another, and the standard "nine-inch" length of *huang chung* was longer or shorter than nine inches in various dynasties.

The role of music in society, education, and government was brought to its highest point of development by Confucius, who advocated government by rituals and music, favored the kind of music that would calm the passions and feed the heart, and condemned the lewd music of Chêng, the "Lyian airs" of China. His influence has been strong for more than 2,400 years. During the wholesale slaughter of scholars and the burning of books under Shih Huang Ti (r. 247 or 246–210 B.C.) of the Ch'in dynasty, innumerable music manuscripts and treatises were lost, and with them many musician scholars. These losses proved a serious blow to musical development. The emperors of the succeeding Han dynasty paid particular attention to the revival of old music.

Music reached its highest peak in the T'ang dynasty, when huge orchestras, numbering from 500 to 700 instruments, performed at the imperial court. Since this climactic period there has been a gradual decline in music in China, especially since the 17th century. It is said of certain music that Confucius, after hearing it, forgot the taste of meat for three months. This the Chinese now speak of as the "lost music." In the 20th century Western music has drawn an increasing

number of Chinese converts, many of whom have little regard for their own music.

Musical Theories.—The principal Chinese tonal system is the *lü-lü* system, consisting of 12 pipes—6 male *lü* (fourth tone) and 6 female *lü* (third tone). The longest pipe is the standard pitch pipe, the *huang chung*, which, by *san fên sun fa* (method of adding and subtracting by thirds), begets all the others. The second pipe is related in length to the first in the ratio of 2:3; the third to the second in the ratio of 3:4; the fourth to the third in the ratio of 2:3; and so on to the twelfth pipe. Since the result of this system is identical with that of the Pythagorean system of cyclic fifths, some musicologists believe that the Chinese system was derived from that of the ancient Greeks. This conclusion is probably unjustified, since Pythagoras based his system on strings, while the Chinese system was based on pipes. (See PYTHAGOREANISM.)

Unfortunately, the thirteenth pipe produced by the Chinese method did not yield the true octave and all the pipes were not uniform in pitch interval. It was therefore impossible to obtain the ideal of *hsian hsian wei kung* (every *lü* alternately serving as tonic). For this reason, in about 45 B.C., Ching Fang added 48 more *lü*, bringing the total to 60. About 438 A.D., Ch'ien Yüeh-chih found the 60-*lü* system also inadequate. He therefore added 300 more *lü*, raising the total to 360. It became mathematically clear that the sequence based on the 3:2 ratio could never hit the true octave, which requires a ratio of 1:2 to the fundamental tone. In 1596 A.D., Prince Chu Tsai-yü of the Ming dynasty theoretically established the equally tempered scale, more than 100 years before it was worked out in Europe.

The first 5 of the 12 *lü* form the Chinese five-tone scale, represented by the black keys on the piano keyboard beginning with F Sharp. This has been the basic scale of Chinese music from the earliest periods to the present day. The notes are called *kung*, *shang*, *chiao*, *chih*, and *yü*. In the Chou dynasty the sixth and seventh *lü* were added to this scale, the new notes being called *pien-kung* and *pien-chih*, and falling, respectively, a half tone below *kung* and a half tone below *chih*. This is the Chinese seven-tone scale; compared with the Western diatonic major scale, it has a raised fourth. In traditional Chinese music transposition was of major importance. Each *lü* was related to a certain month, and melodies played in each month had to be in the appropriate key. There were various modes, many melodies being written in the *shang* mode, for example, others in the *chiao* mode, and so on.

Musical Practice.—Chinese music is divided into four classes: ceremonial music, chamber music, operatic music, and folk music. The ceremonial music is said to have been "lost." It was slow and dignified, with long-drawn notes of equal length. When sung, it always had one note to a word. Music for the *ch'in* (zither) and *p'i-p'a* (lute) is the most highly developed category of chamber music. Elaborate techniques developed, and many special handbooks were written for these two instruments. An older type of operatic music, called *k'un-ch'ü*, is usually serious. The *ti-tsü* (flute) is its main accompanying instrument, and it may be traced back to the Yüan dynasty. A much later type of opera, *p'i-huang*, which originated about 1850, has the *hu-ch'in* (two-stringed violin) as its main accompanying instrument. It has become very popular and has

largely replaced the *k'un-ch'ü*. Folk music, though almost entirely neglected for centuries by scholars and musicians, has continued to live in the hearts of the people. It reflects the character and life of the Chinese nation.

Chinese music is played or sung largely in unison, sometimes employing parallel fourths and fifths. Its rhythm is most frequently based on the four-measure line. Its melody, because of the influence of the Chinese language, is usually more liquid and more florid than that of the West.

Musical Instruments.—Traditionally, Chinese musical instruments are classified into eight families according to the materials from which they are made: metal (*chung*—bell); stone (*ch'ing*—sonorous stone); silk (*ch'in*—zither, which has silk strings); bamboo (*p'ai hsiao*—panpipes); gourd (*shêng*—mouth organ); clay (*hsün*—ocarina); skin (*ku*—drum); and wood (*yü*—"comb-backed tiger" for stopping the performance). Many types originating among non-Chinese tribes or in foreign countries were later absorbed into the family of Chinese musical instruments.

Notation.—There are two kinds of Chinese musical notations. The first pertains to the instrument (where to stop the string, which bell to strike) and the method of playing (which finger to use, how to pluck the strings, how to stop them as required). The second indicates which pitch (absolute or relative) is to be produced. Neither gives a graphic picture like that presented in Western staff notation. The *lü-lü* notation, using the first characters of each of the 12 *lü* names, originally belonged to the first type and was later developed into the second. The *kung-shang* notation, using scale names, belongs to the second type and is used like the Western movable-do system. The *kung-ch'e* notation, using 10 characters and their modifications to represent various pitches, originated from the notation of certain wind instruments and was later adapted to other instruments and to vocal music. In the *ch'in* notation, used exclusively in playing instruments of the *ch'in* type, a single symbol indicates what, where, and how both hands are to play. The *p'i-p'a* notation, use of which is limited to the instrument of the same name, is a combination of the *ch'in* and *kung-ch'e* notations.

The *ch'in* and *p'i-p'a* notations are still used for their respective purposes, while the *kung-ch'e* notation is used in music of the old school. In addition, numerical notation has been introduced from Japan; Western staff notation is used increasingly in the schools; and the tonic sol-fa notation is used in some church schools.

Influence of Language on Music.—The tonal and basically monosyllabic character of the Chinese language has had a tremendous influence on Chinese music. There is a natural tonal curve in the spoken language. When words are set to music, the melodic curve does not go its own way regardless of the already established tonal curve of the text. Moreover, each of the four inflections of Standard Chinese (Mandarin) has a tendency of its own, calling for special treatment. (See section on *Language*.)

The characteristic tonal features of Chinese music give it a flow and a floridity deeply satisfying to the Chinese ear. Centuries ago the influence of these elements penetrated the realm of instrumental music. They are basic in the music of modern China, and of potential benefit to the entire musical world.

6. ART. Architecture, painting, and sculpture have long been regarded as the three principal fine arts, and these alone will be treated in this article. For an account of the fascinating minor art of pottery and porcelain, see section on *Ceramics*; for bronzes, see *BRONZE*.

ARCHITECTURE

Although the ancient Chinese never considered architecture a fine art, in China as in the West it has been the mother of the fine arts. It was through the medium of architectural decoration that painting and sculpture gradually matured and gained recognition as independent arts.

Technique and Forms.—The architecture of China is an indigenous system of construction which was conceived in the dawn of Chinese civilization and has been developing ever since. Its characteristic form is a timber skeleton or framework standing on a masonry platform and covered by a pitched roof with overhanging eaves. The spaces between the posts and lintels of the framework may be filled in with curtain walls whose sole function is to separate one portion of the building from another, or the interior from the exterior. The walls of the Chinese building, unlike those of the conventional European building, are free from the weight of the upper floors and the roof, and may be installed or omitted as required. By adjusting the proportion of the open and walled-in spaces, the architect may admit or exclude just the amount of light and air appropriate to any purpose and to any climate. This high degree of adaptability has enabled Chinese architecture to follow Chinese civilization wherever it has spread—to Korea and Japan in the east, to Sinkiang in the west, to Indochina in the south, and to the Siberian border in the north.

As the Chinese system of construction evolved and matured, rules like the orders of classical European architecture were developed to govern the proportion of the different members of the building. In buildings of a monumental character the order is enriched by *tou-kung*, sets of brackets on top of the columns supporting the beams within and roof eaves without. Each set consists of tiers of outstretching arms called *kung*, cushioned with trapezoidal blocks called *tou*. The *tou-kung* are functional members of the structure, carrying the beams and permitting the deep overhang of the eaves. As they evolved, they assumed different shapes and proportions. In earlier periods they were simple and large in proportion to the size of the building; later they became smaller and more complicated. Hence they serve as a convenient index to the date of construction.

The planning problem of the Chinese architect is not that of partitioning a single building, since the framing system makes the interior partitions mere screens, but of placing the various buildings of which a Chinese house is composed. These are usually grouped around courtyards, and a house may consist of an indefinite number of such courtyards. The principal buildings are usually oriented toward the south, so that a maximum amount of sunlight can be admitted in winter, while the summer sun is cut off by the overhanging eaves. Apart from the variations required by special topographical conditions, the same general principles apply to all domestic, official, and religious architecture.

Historical Development.—The oldest architectural remains in China are some tombs of the Han dynasty. Both the burial chamber and the *ch'üeh*, or gate piers, include translations into stone of timber construction, showing a highly accomplished carpenter's art rendered by an equally masterful touch of the sculptor's chisel. The important role played by the *tou-kung* is seen even in that early period.

No timber structure built during the long interval up to the middle of the 8th century A.D. has as yet been found standing in China. Yet glimpses of the outward appearance of such structures may be gathered from the details of construction in some of the cave temples and from the paintings on their walls. In the caves of Yunkang, near Tatung, Shansi, constructed about 452-494 A.D., and in those of Hsiangtang Shan, on the border of Honan and Hopeh provinces, and Tienlung Shan, near Yanku (Tai-yuan), Shansi, which were built about 550-618 A.D., the façades and interiors are treated architecturally, carved from the rock cliffs to emulate the contemporary timber structures. On the tympanum of the west portal of the Tz'u-en Ssü pagoda (701-704 A.D.), in Sian (Changan), Shensi, is an engraving showing in accurate detail a Buddhist temple hall. The frescoes on the walls of the 6th to 11th century caves at Tunhwang, Kansu, are paradise scenes with elaborate architectural backgrounds. These relics are graphic records of the architecture of a period that has left us no standing specimens. Here, too, we notice the importance of the *tou-kung*, whose evolution may be clearly traced.

Such indirect evidence of the character of early Chinese architecture is well supported by groups of buildings still standing in Japan. They were erected in the Suiko (Asuka), Hakuho, Tempyō, and Kōnin (Jogan) periods, corresponding to the Sui and Tang dynasties in China. In fact, until the middle of the 19th century the architecture of Japan reflected as in a mirror the changing styles of continental builders. The early Japanese structures may justifiably be called colonial Chinese, and some are actually known to have been erected by continental architects. Earliest of these is the Hōryūji group, near Nara, which was constructed by Korean builders and completed in 607. Another is the Kondō of the Tōdaiji, Nara, built by the Chinese monk Ganjin (Chien-chên, d. 763) in 759.

The oldest extant wooden structure in China itself is the main hall of the Buddhist temple Fo-kuang Ssü, Wutai, Shansi. It is a one-story building of seven bays, with *tou-kung* of gigantic size, showing an unparalleled vigor and dignity in proportion and design. The temple was built in 857, shortly after the nationwide

T'ang Yin (1470–1523) painted the scroll, of which this is a section, called "Scholar Receiving Buddhist Friend," in 1509. Ming dynasty.

Courtesy Museum of Fine Arts, Boston

This landscape scroll of mountains and water was done by Tung Yüan. Late 10th century. Sung dynasty (960–1279 A.D.).

Buddhist persecution of 845. It is the only wooden structure known to date from the T'ang dynasty, the golden age of Chinese art. The hall houses specimens of sculpture and calligraphy and a fresco frieze, all of the same period. The congregation in one spot of all the major arts of T'ang date makes this temple and its contents a unique treasure in China.

Wooden structures of later periods are found in increasing numbers. A few of the more outstanding monuments may be chosen to represent the Sung dynasty, together with the contemporaneous Liao and Chin dynasties.

The Hall of Kuan-yin (Goddess of Mercy) of the Tu-lo Ssü, Chih-sien, Hopeh, was built in 984. It is a two-story structure containing an eleven-headed Kuan-yin, standing upright. A mezzanine story is inserted between the two main stories, so that the structure is actually built of three superposed "orders." Here the function of the *tou-kung* is shown to best advantage.

The group of buildings at Tsintzu, near Yanku, was built about 1025. The two principal buildings are each one story in height, but the main hall has double-decked eaves. The main hall of the Hua-yen Ssü, Tatung, is a huge single-story structure with single-decked eaves. Built about 1090, it is one of the largest Buddhist structures in China. Of considerably later date (1260) is the main hall of the Pei-yüeh Miao, Chuyang, Hopeh. The inner structural members supporting the upper part of the roof have been extensively rebuilt, but the lower part and the outward appearance of the building as a whole are essentially unaltered.

A comparative study of these few examples reveals that the *tou-kung* tends to become smaller and smaller in proportion to the building. Another common characteristic is an increase in the height of the columns toward the corners of the building. This latter refinement brings about a gentle curvature of the eave line (with the exception of the Hua-yen Ssü hall), and of the roof ridge, giving an appearance of great elegance.

With the coming of the Ming dynasty, the subtle refinements disappeared. This trend is especially noticeable in the monuments built under imperial patronage, and is best exemplified in the sacrificial hall at the tomb of Emperor Chu Ti (reign name, Yung-lo), built in 1425 at Changping, Hopeh. Here the *tou-kung* has shrunk to insignificance; its presence can be detected only at close view.

Despite the retrogressive features of individual buildings of the Ming and Ch'ing dynasties, we have in the imperial palaces of Peking a superb example of planning on the grandest scale, showing the aptitude of the Chinese for conceiving and executing a design of colossal proportions. The hundreds of audience halls and apartments within the Forbidden City, a walled enclosure measuring about 3,350 feet by 2,490 feet, are mainly structures of the late Ming and the Ch'ing dynasties. The entire area was conceived as a single architectural unit, with one main axis dominating the Forbidden City and the entire Imperial City surrounding it. The halls, pavilions, verandas, and gates are grouped in innumerable courtyards connected by colonnades. The buildings themselves are raised on white marble terraces. Columns and walls are generally painted red, while the *tou-kung* are decorated with intricate designs in blue, green,

and gold, forming a cool belt which accentuates the deep, shady overhang of the eaves. The whole structure is crowned by a roof of glazed yellow or green tiles. The ingenuity of the Chinese in applying color to architecture on an all-inclusive scale has never been equaled.

Multistoried Timber Structures.—Because of the limitations of the material, high structures in timber are rare. The best known is the Ch'i-nien Tien of the Temple of Heaven, Peking. It is a building of circular plan, standing on three tiers of white marble terraces and crowned by three tiers of blue glazed tile roofs, the uppermost of which converges into a cone whose apex is about 108 feet above the ground.

The finest example of multistoried timber construction in China is the little-known wooden pagoda of Yinghsien, Shansi. Erected in 1056, it is a five-story structure with four additional mezzanine stories, built on an octagonal plan. Each of its main and mezzanine stories is a complete "order" in itself. The pagoda as a whole therefore comprises nine superposed "orders." Scarcely any of its members is idle: every timber has its part in supporting the building. The top roof, which is an octagonal cone, is surmounted by a wrought iron spire whose tip is 215 feet above the ground. Although most of the early pagodas were of wood, this is the only one of its kind still standing in China.

Masonry Pagodas.—The early wooden pagodas have disappeared, but many of their counterparts in brick—or, in rare cases, stone—have survived the destructive forces of man and nature. Contrary to the general assumption, the design of the Chinese pagoda was not imported from India; rather, it is a cross between the architectural ideas of the two civilizations. The body is entirely Chinese, the Indian element finding expression only in the spire, which is derived, often in much modified form, from the stupa. Many of the pagodas are brick and stone translations of wooden prototypes embodying the traditional Chinese architectural conceptions.

Chinese masonry pagodas may be divided into five principal types:

One-Story Pagodas.—A stupa is a monument marking the site where some Buddhist relic is buried; the tomb stupa of a deceased monk may properly be called a pagoda. Most of the tomb stupas of the 6th to the 12th centuries are small, square pavilionlike structures, one story high, with one or two strings of cornices. The earliest examples of the one-story form is the Ssü-mên T'a (which is not a tomb), built in 544 near Tsinan, Shantung. More typical is the tomb of Hui-ch'ung at Ling-yen Ssü (mid-7th century), Changching, Shantung.

Multistoried Pagodas.—The multistoried pagoda retains most of the characteristics of the indigenous multistoried building. Counterparts in wood are still extant in Japan, but only brick structures of this type remain in China. One of the earliest and best examples is the Hsiang-chi Ssü pagoda, built in 681, near Sian. It is a square pagoda of 13 stories, 11 of which are intact. The stories are marked by strings of corbeled cornices, and the exterior walls of each story, in addition to their doorways and windows, have delicate reliefs of simple pilasters and architraves supporting *tou*.

In the Sung dynasty the octagonal plan became general. Representation of columns or pilasters on the walls is often omitted, but the

cornices are in most cases supported by numerous *tou-kung*. In some instances, such as the twin pagodas of Tsohsien, Hopeh (c.1090), the outward appearance of the wooden pagoda has been faithfully reproduced in brick.

Multi-eaved Pagodas.—The multi-eaved type seems to be a mutation of the single-story pagoda, produced through increasing the number of cornices. In appearance, it presents a high main story crowned by a great number of closely decked eaves. The earliest example is the 12-sided, 15-story pagoda of Sung-yüeh Ssü, built about 520, on Sung Shan, a sacred mountain in Honan. During the T'ang dynasty the square plan was the only one chosen for this type of pagoda. The pagoda of Fa-wang Ssü (c.750), also on Sung Shan, is an excellent example.

The octagonal plan was introduced about the middle of the 9th century and after the 11th century became accepted as the standard shape for a pagoda. A great number of pagodas of this type, enriched by *tou-kung* under the eaves, were built in north China from the 10th to the 12th centuries. The best-known example is the pagoda of the T'ien-ning Ssü, Peking, a structure of the 11th century which has been much repaired.

Stupas.—The stupa in its original Indian form, though known in China through the early Buddhist missionaries, was never transplanted there. When the stupa finally did become established in China, in much modified form, it arrived through Tibet in conjunction with the spread of Lamaism. The Tibetan stupa is generally bottle shaped and raised on a high base. The best example is the stupa of Miao-ying Ssü, Peking, which was built in 1260 by Kublai Khan. Later the bottle became more slender, particularly the neck. This part, which originally resembled a truncated cone, came to resemble a smokestack. Typical of the later stupas of the Tibetan type is the one in North Lake Park, Peking, built in 1651.

Diamond-Based Pagodas.—The *chin-kang pao-tso t'a*, or diamond-based pagoda, consists of a group of pagodas on a common base. Its development was foreshadowed as early as the 8th century in the pagoda group of Yün-chü Ssü, Fangshan, Hopeh, which is composed of a large pagoda and four small ones on a single, very low platform. The form did not reach full architectural maturity until the Ming dynasty. An excellent example is the Wu-t'a Ssü (Five Pagoda Temple), built in 1473 outside one of the west gates of Peking. This structure reminds the observer in various ways of the 8th century Boro Budur in Java.

Beamless Halls.—As we have noted, timber has always been the principal Chinese building material, and pure masonry is seldom used except in pagodas and bridges. Toward the end of the 16th century, however, a few vaulted brick buildings were constructed. Their exteriors conform to the Chinese "order" of architecture in much the same way as the façades of the Renaissance buildings of Europe conform to the classical Greek and Roman orders. Inside, the dome and even the pendentives are ingeniously treated with tiers of cantilevering *tou-kung*.

This type of architecture never became popular in China, and existing examples are rare. Outstanding among them are the beamless hall of the Yung-Chao Ssü, built in 1595 near Yanku, and that of the K'ai-yüan Ssü, in Wuhsien.

P'ai-lou.—In most of the towns and on many of the country roads of China are found monumental archways called *p'ai-lou*. Although the *p'ai-lou* is considered a purely Chinese architectural concept, one cannot fail to notice an analogy between this form and the gateways of the railings surrounding certain Indian stupas, such as those of Sanchi. In south China stone *p'ai-lou* are common; in northern cities the street scene is often enlivened by gaily painted timber ones.

Bridges.—The building of bridges is an ancient art in China. Early examples were either simple timber structures or pontoon bridges, and it was not until the middle of the 4th century A.D. that the arch was used to span a water barrier. The most notable example of Chinese bridgebuilding is the Great Stone Bridge, Chaohsien, Hopeh. This is an open-spandrel bridge (one with small arches piercing the triangular space between the roadway and the ends of the main arch) whose principal arch has a span of 123 feet. Built in the Sui dynasty, it is a feat of engineering to amaze even a modern engineer. The commoner type of bridge, exemplified by the celebrated Marco Polo Bridge near Peking, uses intermediate piers. Suspension bridges are often employed in the mountainous regions of south-western China, and bridges with huge stone lintels, sometimes measuring 70 feet or more, are not uncommon in Fukien.

PAINTING

Painting as an art first appeared in China in the form of decorations on banners, dresses, gates, walls, and other surfaces. The aesthetic appeal and suggestive power of this medium were utilized by kings and emperors of the earliest days as a convenient means of teaching and governing the people.

Pre-T'ang Painting.—In the Han dynasty the art of painting reached technical maturity and murals were used to decorate the interiors of halls and palaces. In 51 B.C., Emperor Hsüan Ti (r. 73-49 B.C.) ordered portraits of 11 of his ablest generals and ministers, who had brought about the surrender of the *shan-yü* (king) of the barbarian Hsiung-nu, painted on the walls of Ch'i-lin Ke—an indication that portrait painting had already become a recognized art. Paintings were executed on walls and on silk. A considerable number of paintings on silk are reported to have been included in the imperial collections of the T'ang dynasty, but these have disappeared.

A painted brick discovered in a tomb at Naknang (Lolang), Korea, which was the capital of a Chinese province from 108 B.C. to 313 A.D., is in the Museum of Fine Arts, Boston. (This museum and the British Museum in London contain the best collections of Oriental art outside Asia.) It affords a glimpse of painting in a frontier province of the great Han empire. Numerous stone slabs with designs engraved or in relief also provide indirect but valuable evidence of the character of Han mural painting.

The oldest existing Chinese scroll painting, attributed to Ku K'ai-chih (344?-2406 A.D.), is treasured in the British Museum. Ku K'ai-chih was a celebrated painter of the Tsin (Chin) dynasty. The scroll, probably a T'ang copy, is labeled *Admonitions of the Instructress to the Court Ladies* and depicts scenes illustrating a series of proverbs or morals. The figures are

painted with a brush on silk, in lines of great accuracy and dexterity, but no attempt was made to set them against a background. The painting shows conceptions of the human form and of space which still adhere to some extent to the archaic methods of presentation on the Han relief stone slabs. Yet it also contains the essential characteristics of the 5th and 6th century Buddhist sculpture.

Painting of the T'ang Dynasty.—Painting, like other branches of art, blossomed into its full glory during the T'ang dynasty. Yen Li-teh and his brother Yen Li-pên (c.600–673) are the first of a long list of great T'ang painters. Li-teh was also an architect, while Li-pên was the greater painter. Attributed to the latter is the scroll *Portraits of Emperors and Kings*, in the Museum of Fine Arts, Boston, in which many of the characteristics of the Ku K'ai-chih scroll are traceable.

Wu Tao-tzu (c.700–760) became the most celebrated Chinese painter. The first to make full use of the flexibility of the brush, he employed undulating lines varying in thickness, with third dimensional effects. This was a radical departure from the wirelike lines of the earlier painters and gave him greater freedom of expression. "Wu's wind-blown draperies" became a phrase familiar to every student of Chinese painting, and succeeding painters depicted movement ever more vividly. Wu, with his free and masterly brush, excelled in painting subjects of all kinds, sacred and secular—figures, animals and plants, landscape, and architecture. The number of his murals recorded in the *Li-tai Ming-hua Chi* (*Famous Paintings of All Ages*) by Chang Yen-yüan (late T'ang) totals more than 300. All have been destroyed.

By the T'ang dynasty, decorating temple walls with paintings had become almost a universal practice. Several hundred items are recorded in the *Li-tai Ming-hua Chi*: scenes of paradise and hell, images of Buddha, Bodhisattvas, lokapalas, demons, and other legendary beings. And these were from collections in the two capitals only—from Sian and Loyang (Honan). There were also many paintings by lesser artists in other cities and on the sacred mountains. Almost no works of this kind have been preserved in the central provinces, but the caves of Tunhwang on the Silk Road are a rich source of information on Buddhist mural painting in a frontier province.

By the beginning of the 8th century landscape, which was to become the noblest form of Chinese painting, had freed itself from its role as a mere background to figure painting. Li Ssü-hsün, who was born about 651 and died in 716 or 720, and his son, Li Chao-tao, are generally recognized as the liberators of landscape painting. Known as the Two Li Generals, they founded the Li or northern school of painting. The work of this school is characterized by careful, wirelike drawings colored with bright blue and green and accented with specks of gold and vermillion. It is highly decorative but somewhat stiff, with every detail minutely and laboriously depicted. While the Two Li Generals were perfecting this style, Wu Tao-tzu painted on the walls of the T'ang palace, in one day, in ink and only faintly tinted with colors, the panoramic *Three Hundred Li on the Chia-ling River*—a work widely different in technique and style from the products of the Li school.

About a half century later, the poet-painter

Wang Wei (699–759) was to be hailed as the master of ink landscape. His work, in contrast to the rigid draftsmanship of the Li school, is characterized by boldness and freedom. Wang Wei excelled in depicting mist and water and was the first to succeed in capturing atmosphere in nature. It is said of him that there are pictures in his poetry and poetry in his pictures. He, too, had his followers, and was hailed by Ming critics as the founder of the southern school of landscape painting, just as the Li Generals were called the founders of the northern school.

Among other great T'ang painters were Ts'ao Pa and Han Kan (fl. c.750), both celebrated for their pictures of horses, and Chou Fang and Chang Hsuan (late 8th century), who depicted domestic and feminine scenes. A copy of one of Chang's scrolls, made by Emperor Hui Tsung (r. 1101–1125) of the Sung dynasty, is in the Museum of Fine Arts, Boston.

Five Dynasties and Sung.—During the chaotic Five Dynasties period there flourished a number of artists who heralded the great Sung painters. Ching Hao, who lived at the end of T'ang and the beginning of this period, was the master of the great landscapist Kuan T'ung who exerted a tremendous influence on the landscape painting of the Sung dynasty. The monk Kuan-hsiu, who was active about 920, was famous for his figures, particularly lohans, which were to become a favorite subject of Sung painters. Hsu Hsi and Huang Ch'üan were painters of birds and flowers.

Mural painting, though less popular than it had been in the T'ang period, was still common during the Northern Sung dynasty, and a few Sung murals have escaped destruction and survived for posterity. In the Tunhwang caves are examples of the work done in a frontier province.

Working at the court academy under imperial patronage were such great painters as Kuo Hsi (c.1020–1090), the landscapist, and Huang Chü-ts'ai, son of Huang Ch'üan, who like his father painted birds and flowers but was a finer artist. Kuo Hsi's favorite subject was the snow scene, featuring bare trees with entwined branches. He is said to have originated the art of mural landscape modeling, in which the subject is worked out in relief in clay and then painted in color.

Among the scholar painters of the early Sung period, Li Ch'êng and Tung Yüan (late 10th century) are generally recognized as the greatest landscapists. Tung Yüan's scenes usually encompass a wide vista. His mountains, which are projected in soft, gentle brush strokes, are often interspersed with rugged, bony rocks, while the velvety, misty quality of a view may be accentuated with proud trees. A few of his masterpieces have been preserved, including a superb scroll in the Museum of Fine Arts, Boston. Another painter, Fan K'uan, often covered his hilltops with heavy vegetation, and placed high, rugged cliffs along riverbanks. Mi Fei (1051–1107) filled his scenes with heavy mists and clouds, and rendered his protruding hilltops with the horizontal, broad, short "eggplant" strokes so much imitated by later painters.

Li Lung-mien (Li Kung-lin, 1040–1106) is well known to the Western world. His line drawings of figures and horses, executed with extreme facility and dexterity, are examples of the highest achievement in draftsmanship.

Toward the end of the Northern Sung dynasty, Emperor Hui Tsung, himself an accomplished

artist who aimed at extreme naturalism, became a great patron of art. Nevertheless, though he devoted far more attention to the academy than had earlier emperors, it did not produce any outstanding artist.

While painting in general flourished in the Southern Sung dynasty, Buddhist painting receded into almost complete obscurity. By this time Buddhism had died out in the land of its origin. Confucian scholars launched merciless attacks on it, and the Buddhists themselves, now dominated by the Ch'an (Zen) sect, while not entirely iconoclastic, substituted meditation for image worship. Buddhist painters of this period preferred such themes as "Kuan-yin in White Dress by the Moonlit Pool," "Meditating Sages," or "Sixteen Lohans"—themes which were not bound by rigid rules calling for dignity and symmetry, as were the religious paintings of earlier periods.

In a world dominated by neo-Confucianism and Ch'an Buddhism, painters turned to landscape as their preferred medium of expression. In the late 12th and early 13th centuries the academy numbered a host of great landscape painters, including Liu Sung-nien, Liang K'ai (fl. c.1203), Hsia Kuei (fl. 1195-1224), and Ma Yüan (fl. c.1190-c.1225). Liu Sung-nien excelled in landscape of the blue-and-green (Li) style, and Liang K'ai was a master of the technique of line drawing of human figures against a landscape background, also in line. But the two great figures in ink landscape of the Southern Sung dynasty were Hsia Kuei and Ma Yüan. Hsia Kuei's strength and boldness are best seen in his famous *Ten Thousand Li of the Yangtze River*. Ma Yüan, who placed his horizons rather low, is more readily appreciated by Westerners. His landscapes, in contrast to those of Hsia Kuei, are marked by tranquility and delicate atmosphere, best illustrated by a pine tree silhouetted against a misty background, a motif familiar to every student of Chinese painting. Up to his time, Chinese landscape painters had tried to include all they saw. Ma Yüan's compositions show merely a few rocks and one or two trees. This pattern—simple in construction and sparse in detail—is perhaps closer to the Western conception of landscape painting than the all-inclusive pattern. It profoundly influenced the painting of the Yüan dynasty.

Yüan Painting.—The comparatively short Yüan period had a number of great painters. Chao Mêng-fu (1254-1322), best known as a painter of human figures and horses, was equally at home with landscape. He was also a calligrapher of the first rank. His best-known work is the *Horse with Groom*. Among the scholars who avoided Mongol officialdom was Ch'ien Hsüan (1235-c.1290), renowned as a painter of flowers, birds, and insects.

Wu Chên (1280-1354), Huang Kung-wang (1264-1354), Ni Tsan (1301-1374), and Wang Mêng (d. 1385) are honored as the Four Great Masters of Yüan. They were all landscape painters. Wu Chên treats his material somewhat heavily, but he has a keen sense of space. He is also well known for his bamboos. In striking contrast are the airy scenes of Huang Kung-wang and Ni Tsan, who used washes very sparingly, obtaining their effects with lines consisting mainly of dry brush strokes. This is particularly true of Ni Tsan, who emphasized this style through his choice of extremely simple

subjects. Wang Mêng painted his scenes heavily, building them up laboriously with individual strokes.

Painting of the Ming and Ch'ing Dynasties.

—The Ming dynasty, relatively recent, has left us many paintings. Mural painting became rare, but some examples which have come down to us, such as those in the Fa-hai Ssü, near Peking, show superlative craftsmanship. Yet connoisseurs and critics do not classify these murals as art, looking to the scrolls alone for the work of the great masters. Early Ming academicians strove to emulate T'ang and Sung paintings, but the spirit of their work is entirely different. Wu Wei, the landscape painter, who modeled himself on Ma Yüan, became the founder of the so-called Che (Chekiang) school. Pien Wên-chin (Pien Ching-chap, fl. c.1430) and Lü Chi (fl. c.1500) were well known for their flowers and birds in the manner of Huang Ch'üan and Huang Chü-ts'ai; Lin Liang founded a school in which the same subjects were treated in an extremely facile and sketchy manner. The leading exponent of the Che school is Tai Chin (Tai Wên-chin, fl. 1430-1450), originally an academician, but expelled from the academy through the intrigues of jealous colleagues. Like all painters of the period, he modeled himself upon Sung masters—specifically, on Ma Yüan—but created a style of his own, simple and articulate in stroke, light in rendering.

Both the academic and the Che schools gradually died out, the latter being reincarnated in the "literary man's style," best represented by the Four Masters of Ming: Shên Chou (1427-1509), T'ang Yin (1470-1523), Wên Cheng-ming, and Tung Ch'ü-ch'ang (1554-1636). Shên Chou is a master in treating a variety of subjects. His style is facile and ethereal. T'ang Yin excelled in both figures and landscapes. His figures are neither stereotypes nor graphic presentations of an ideal, but honest portrayals of life. Wên Cheng-ming painted landscapes with articulate brush strokes and light washes. Tung Ch'ü-ch'ang's landscapes enclose wide vistas and show a keen sense of space and atmosphere.

Ch'iu Ying (fl. 1522-1560), who learned his craft as a lacquer painter, was a master of detail. In his paintings we see the pleasures of everyday life exquisitely and faithfully recorded.

A salient characteristic of Ming painters is their masterly manipulation of the brush. It does not merely make a line or a wash; it conveys tone, strength, and spirit. In this dynasty the technique of the brush attained perfection.

Ch'ing dynasty art is a continuation of the Ming tradition. Early in this period the southern school of landscape painting, best represented by the four Wangs—Wang Shih-min (1592-1680), Wang Chien (1598-1677), Wang Hui (1632-1717), and Wang Yüan-ch'i (1642-1715)—came into prominence. Wang Shih-min and Wang Chien, who took Tung Yüan and Huang Kung-wang as their masters, formed the vanguard of Ch'ing painting. The former is known for his bold brush strokes. Wang Hui was a disciple of Wang Shih-min, and excelled him in control of the medium. He is said to have combined the northern and southern schools, and was proclaimed by his master as the Sage of Painting. Wang Yüan-ch'i, grandson of Wang Shih-min and the most learned of the four, best caught the spirit of Huang Kung-wang. He is known for his landscapes with light tinges of color.

Ch'ên Hung-shou (1599-1652) originated a style in which, despite an appearance of carelessness, each stroke is skillfully conceived and precisely executed. He had many imitators. Shih T'ao was another "careless" painter of landscapes and bamboos. Both men reached maturity in the Ming dynasty, but they lived into the early years of Ch'ing, and their influence on later painters places them as artists of the later rather than of the earlier dynasty.

SCULPTURE

Sculpture, like architecture, was not accorded due recognition by the Chinese. While we know something of the great painters, the sculptors are anonymous.

Early Sculpture.—The oldest specimens of Chinese sculpture were found in the Shang dynasty tombs at Anyang. The owl, tiger, and turtle are favorite motifs, and the human figure also appears occasionally. These marble pieces are in the round, some of them being architectural elements. Their surfaces are decorated with patterns like those found on the contemporary bronzes. In decorative pattern, in basic concepts of form and mass, and in spirit, the sculpture and the bronzes are one. Bronze masks have also been found, some of the *t'ao-t'ieh*, some of human beings. They are often well modeled.

Human figures and animals in the round began to be used as decorative motifs on the bronzes around 500 B.C. The human figures were first carved in the kneeling position, molded in strict conformity with the *law of frontality*, but the art soon freed itself to portray action. In general, the human figures are short and stubby, rendered with little feeling for modeling, but the animal forms show keen and subtle touches of the chisel, based on careful observation of nature.

Han; Three Kingdoms; Six Dynasties.—In the Han dynasty sculpture gained importance in conjunction with architecture. Reliefs decorate interior wall surfaces, such as those found in a number of tomb shrines, notably the tombs of the Wu family at Chiahsiang, Shantung. Human figures and animals (lions, lambs, and chimeras) in the round stand in pairs flanking the avenues leading to tombs, temples, and palaces. At Kufow (Chüfou), Shantung, the human figures are typically rigid, lumpy, and ill modeled, bearing only a vague resemblance to the human form. Yet the animals are in general well modeled, robust, vigorous, and animated. The lions and chimeras are usually winged. (Since figure sculpture, animal or human, had never been employed by the Chinese of earlier times as guardian monuments to an architectural approach, it is possible that the idea was imported from the Occident through contact with the barbarian tribes of the west and north.) On some of the contemporary *ch'üeh* in Szechwan are found reliefs of birds, dragons, and tigers that rank with the best decorative sculpture.

With the spread of Buddhism during the period of the Northern and Southern dynasties, anthropomorphic sculpture assumed an important role. A few small images of the early 5th century have come down to us. The first important monuments are in the caves of Yunkang, near Tatung, first capital of the Northern Wei dynasty (386-534 A.D.). These are undoubtedly Chinese versions of Buddhist caves in India. Yet, aside from decorative motifs (the acanthus leaf, the frets, the beads, and even the Ionic and

Corinthian capitals) and the basic conception of the caves themselves, there seems to be no traceable Indian influence to give the sculpture an Indian or otherwise un-Chinese character. There are a few characteristically Indian figures, but the group remains essentially Chinese.

The work on the caves near Tatung was begun by imperial order in 452 and stopped abruptly in 494, when the capital was moved south to Loyang. The plan of some of the caves is fairly similar to the chaitya caves of India, with the chaitya, or stupa, in the center. The architecture and sculpture, however, are basically Chinese. The earliest, and larger, figures, some measuring over 70 feet in height, are heavy and sturdy. The pleated draperies cling to the body. Later the figures grew more slender, and the head and neck became almost tubular. The eyebrows are arched and join with the bridge of the nose. The wide forehead is almost flat, turning sharply back at the temples. The eyes are mere slits; the lips, thin, forever smiling. The chin is often sharply pointed—a feature especially noticeable in some bronze statuettes of the period. The draperies no longer cling to the body, but hang from it, often flaring out at ankle level, and are arranged symmetrically on the right and left, with the pointed, almost knifelike, ends of the folds spread out like a bird's wings. (It is not by accident that pointed ends are also characteristic of the strokes of the calligraphy of the period.) The Bodhisattvas of these statuary groups, whose Indian counterparts wear princely attire, are stripped of most of their ornaments. They wear a simple tiara and a heart-shaped necklace, and from the shoulders of each figure hangs a long sash, the ends crossing through a ring hung in front of the thighs.

A project similar to that at Tatung was begun by the Wei emperors about 495 at Lungmen, near Loyang, on the cliffs of the I (Yi) River. Here the heads are less tubular and more rounded, and the draperies less pointed and more fluent, though still symmetrically arranged, achieving a superb decorative effect. The walls of some of the caves are decorated with reliefs representing the emperor on one wall and the empress on the opposite one, each attended by an entourage, forming compositions of the highest order. The activity of the cliff sculptors at Lungmen continued until the latter part of the 9th century.

When, in 534, the Northern Wei dynasty split into the Eastern (534-550) and Western (535-556) Wei dynasties, these new states were each soon usurped by powerful ministers, who founded the Northern Ch'i (550-577) and Northern Chou (557-581) dynasties. The Ch'i rulers were devout but extravagant Buddhists. Yet it was not until nearly the end of their brief dynasty, just before its overthrow by the rival Chou, that they began the caves at Tienlung Shan. Contemporary with these caves are those of Hsiang-tang Shan. Most of the figures of these caves assume a standing posture. Their heads are almost round. The forehead is markedly lower; the eyes, though still very narrow, are wider. The nose and lips are fuller, with the enchanting smile of earlier periods almost completely suppressed. The chin has become less pointed and often has a crescent-shaped groove suggesting a double chin. The draperies are simpler, hanging almost vertically with hardly any flare at the hem. In some specimens found in Szechwan, however, the clinging drapery still appears.

Sculpture of the Sui and T'ang Dynasties.

—In the Sui dynasty the standing figures begin to show a peculiar protrusion of the abdomen. The head has become smaller in proportion to the body, and the jaws and nose are fuller. The eyes, though still narrow, show some convexity in the upper lids, emphasizing the presence of the eyeballs. The slightly convex surface intersects the curved plane under the brow in a gentle "valley." The line of intersection appears as a wide arc, repeating the rhythm of the brow and the eye. The subdued smile is produced by more fully modeled lips, and the mouth is smaller. The neck has assumed the peculiar shape of a truncated cone, protruding sharply from the chest and joining the head with similar abruptness. The cone is circumscribed about halfway up by a groove-like fold. The drapery is shown in more natural folds, and the hem rarely flares. In contrast to the costume of Buddha, which is austere draped in all periods, that of the Bodhisattvas has become more gaudy. The tiara and the necklace are now bedecked with jewel-like ornaments. Strings of beads, hanging from the shoulders and interrupted at intervals with pendants, reach far below the knees.

Sculpture, especially Buddhist sculpture, reached its zenith in China in the T'ang dynasty. The work begun at Lungmen by the Wei Tatars attained new heights, and the creation of Buddhist images was advanced with similar zeal throughout the empire. About the end of the 9th century, however, cave sculpture seemed to lose the interest of the worshippers of central China. It was continued at Tunhwang, but the center for China Proper shifted to Szechwan, which contains many late T'ang caves. The activity in that province continued through the Sung and Yüan periods into the Ming dynasty.

It is difficult to differentiate sharply between the Sui and early T'ang styles, but toward the middle of the 7th century T'ang characteristics definitely emerged. The figures have become more naturalistic. The S-curve appears in most of the standing figures, which are balanced on one leg, with the hip of the relaxed leg and the shoulder on same side slightly lowered. To maintain equilibrium, the head is tilted slightly toward the side of the supporting leg. The body is more fleshy, although the waist remains slim. The face, especially that of the Bodhisattva, is pleasingly plump. The gracefully arched eyebrow is not carried quite so far as in the previous periods, but curves naturally, clearly defining the temple. The ridge of the eyebrow is now seldom incised with groove. The area of the upper eyelid extends farther up, and the curved plane below the brow is narrower. The nose is shorter and less sharply ridged. The lips are definitely sensuous, and the distance of the upper lip from the nose is markedly shortened. The hair is now carried very low, reducing the height of the forehead. The Bodhisattvas of this period are less garishly ornamented. The tiara is often simplified, but the hair is drawn into an enormous knot on top of the head. The garments are modeled to conform closely to the body, and the beads, though still often worn, are bare of most of their former pendants.

About the beginning of the 8th century a very earthly type of Buddha was introduced. He is represented as a complacent, fat creature of this world, with a flabby chin, scarcely any neck, and a full, protruding abdomen—a most unusual

conception of the ascetic who wandered the woods of Buddh Gaya. Not many figures of this type have been found, but all are evidence of superlative achievement in the plastic representation of the human form.

Toward the end of the T'ang dynasty, in the caves of the secluded Szechwan area, there appeared a type of sculpture characterized by the iconographic tributes and fantastic physiology of the newly popular *mi-tsung* or *mi-chiao* (secret sect or religion). In its treatment of the human form and of the draperies, however, it shows no perceptible break with T'ang tradition. An entire wall area is often used for a single subject. The paradise scene, which is pictured over and over again in the contemporary mural painting at Tunhwang, is here executed in relief, forming a single composition—a plastic conception never found in earlier cave sculpture.

T'ang sculptors were extremely skillful in portraying animal forms, many examples of which have been preserved in the grounds of the T'ang imperial tombs. Some smaller pieces are on view in museums of the United States and European countries.

Sung Sculpture.—With the fall of the T'ang dynasty the creation of Buddhist images in stone almost ceased. Statues in Sung temples were carved in wood, modeled in clay, or, rarely, cast in bronze. The only exceptions are found in the caves of Szechwan. Few of the bronze images escaped melting down in later periods. One notable exception is the 70-foot statue of Kuan-yin in Chengting, Hopeh, cast by order of the first Sung emperor, T'ai-tsu (Chao K'uang-yin, r.960-976). Clay figures are numerous. A superb example of this work is the altar group in the Hua-yen Ssü, Tatung. The eleven-headed Kuan-yin of the Tu-lo Ssü Chihhsien, closely follows the T'ang tradition; it measures about 60 feet in height and is the largest clay figure in China. Many wooden statues of the Sung period have found their way to the museums of the West.

The most noticeable characteristic of Sung statues is the rounding of the face. The forehead is broader than in previous periods. The nose is short and almost bulbous. The eyebrows are less arched, and the convex surface above the upper lid is even wider, reducing to a narrow strip the concave plane under the eyebrow. The lips are thicker, and the mouth is very small. The smile has almost vanished. The neck is rendered naturally, emerging above the chest and supporting the head without any demarcation.

The S-curve of the T'ang bodhisattvas seems to have been forgotten. Even when the figure is not completely rigid, the ease with which T'ang figures carry their weight, and the consequent lowering of the relaxed side of the body, seem beyond the grasp of the Sung sculptors. The Ch'an Buddhists introduced a new pose for the Kuan-yin, showing the goddess seated on a rock with one leg hanging down and the other foot resting on the rock. This complicated pose presented the sculptor with new problems of arrangement of the body and the draperies.

Szechwan cave sculpture of the Southern Sung period shows evidence of a decline in the sculptor's art. This is especially noticeable in some of the Bodhisattvas. By this time they have taken on an unmistakably feminine appearance. They are gaudily dressed and overburdened with jewelry and ornaments. The pose is rigid, almost frigid; the expression is blank. The best

CHINA—CERAMICS

These porcelains belong to the K'ang-hsi period (1662-1722), with one exception. All are of the Ch'ing dynasty. Top row, left to right: vase; club shape vase; vase with ox-blood glaze. Center row: A delicate figure; lion with stand; rectangular vase with dragon handles. Bottom row: Bowl with tea-dust glaze (Yung-Ch'eng period, 1723-1735); a deep dish with peacock design.

example of this work is the group of young, matriotlike Bodhisattvas in Tatsu.

Yüan, Ming, and Ch'ing Sculpture.—During the Yüan dynasty, Lamaist Buddhism was introduced from Tibet. With it came sculptors whose influence was to last through the Ming and Ch'ing periods. Most of their figures are shown sitting cross-legged. The waist is almost wasp-like, the chest is broad, and the shoulders are square. The head has become more squat, but the rhythm of the torso is repeated in the broadening of the forehead. The top of the head is flattened and surmounted by a grossly elongated *uṣṇiṣa*, the hump characteristic of the sculptured heads of Buddha.

The Ming and Ch'ing dynasties were a sad period for sculpture in China. The statuary of these periods shows neither the robust vigor of Han, nor the archaic charm of the Six Dynasties, nor the mature self-assurance of T'ang, nor even the rococo elegance of Sung. The sculptor's art had degenerated into uninspired manual labor.

7. CERAMICS. Ceramic manufacture in China antedates the dawn of Chinese history, and articles of fired clay have been common in all periods of Chinese culture. The soil of every province of China abounds in shattered fragments, and ancient Chinese pottery found its way to many foreign lands. Korea has examples from the Han period and every succeeding dynasty of importance. In Japan, T'ang dynasty lead-glazed pottery offered to Buddha at the opening of the Tōdaiji at Nara in 752 A.D., is still preserved there in the Shōsōin. High-fired T'ang Yüeh ware was in use at Samarra in Mesopotamia between 838 and 883 A.D., and at about the same time, or soon after, in Egypt. Turkey was an early recipient of celadon and blue-and-white wares, some designed especially for Moslem use. Lung-ch'üan celadon of the Sung and Ming dynasties and blue-and-white ware are found through-

out the Philippines, in all of Indonesia, on the Malay Peninsula, and in India. More recently, China has supplied porcelain to her own people who have emigrated to the South Seas and all over the world. European and American imports of Chinese ceramics, with the possible exception of the Canton ware which was cleared commercially through Lowestoft, England, have depended largely on the sporadic and fickle demands of connoisseurship.

Guild System.—Chinese potters still ply their craft under group systems—family, village, or guild—which have insured amazing uniformity in wares for centuries. Undisturbed by the caprice of individual potters, these groups have been strongly influenced by inherited local traditions and by a continuous demand for wares meeting traditional standards. The art has always outshone the artist. Both the white porcelain (blanc de chine) of T'ehua, Fukien, and the blue-and-white ware of Chingtehchen (Kingtehchen; now Fouliang), Kiangsi, preserve a living tradition of 500 years. The famous green celadons of Chekiang and the brown-and-white *Ts'ü-chou* wares, despite some shifting of locality and a gradual decline in recent centuries, may each claim a history of at least 1,000 years. Certain names have come down to us, such as those of the Chang brothers of Lungch'üan and the Wang family of Changte, Honan, but these were master craftsmen associated with wares rather than with individual pieces. It is typical of the Chinese tradition that the names of some master potters who never signed a pot were perpetuated through posthumous deification.

Craftsmanship.—Chinese ceramic wares, all types of which are often loosely known as Chinese pottery, are classified by the Chinese themselves under three broad headings: *wa-ch'i* or earthenware, glazed or unglazed; *t'ao-ch'i* or stoneware, usually glazed; and *ts'ü-ch'i* or porcelain, glazed, resonant, and sometimes translucent. The Chinese have been unexcelled craftsmen in all three fields.

Simple coil and paddle methods, common in prehistoric times, have never been entirely discarded, while the potter's wheel associated with latter-day porcelain is of very early origin. Rapid turning was practiced long before the 1st millennium B.C., and clay slip in one or more layers was used from the earliest times. The Chinese embellished their wares by polishing (with an effect similar to the so-called glaze of Greek ceramics), painting, incising, comb marking, kneading, embossing, reticulating, glazing, crackling (or crazing), and enameling. Natural effects were admired and cleverly controlled. The use of molds, both patrices and matrices, and slip casting were common at various times. Saggers were often used in firing in the Sung dynasty and possibly much earlier. Indeed, there are few ceramic processes which have not been employed in China, and the influence of her potters' art has been felt throughout Asia and has had a tremendous effect on European ceramic products since the 15th century. Every piece of porcelain the world over is of Chinese ancestry.

Bricks and Tiles.—To the simplest category of ordinary earthenware belong the *chuan wa* (bricks and tiles or terra cotta) employed for centuries in Chinese building. A good example of their use is the Great Wall, a large part of which is constructed of huge gray bricks. Inscriptions appear on enough of these to show that

they have been used for building and repair for at least 2,000 years. Similar large bricks were normally used for the handsome, massive walls that still enclose most of the old cities of China. Plain gray clay tiles, heavy and durable, are the commonest roofing material in most parts of modern China, and their use can be traced back at least to the Chou dynasty, some extant examples bearing Chou-style ornament. Other architectural features frequently made of brick or tile are flooring, flagging, and the walls of buildings and courtyards.

From tomb walls of the Han dynasty and perhaps earlier come hollow, rectangular tiles up to six feet in length, typical examples of which have stamped or painted ornaments. The high-fired glazed roof tiles of the Yüan, Ming, and Ch'ing dynasties are famous. Yellow tiles were reserved for imperial usage or for buildings under imperial patronage, such as the roofs of the Forbidden Cities of Peking, Kaifeng, Nanking (no longer standing), and the Manchu capital, Shenyang (Mukden, formerly Fengtien), and for the outer surfaces of the "iron" pagoda at Kaifeng and the former so-called porcelain tower at Nanking. Other buildings—for example, the Temple of Heaven, Peking—have roofs of blue tile; still others, of green. Such roofs usually bear architectural ornaments of sacred, supernatural figures. Typical ornaments are pairs of fire-eating dragon-fish facing each other from the opposite ends of a ridgepole, representing opposing natural forces in proper balance. Tile work, in relief, in the aforementioned colors as well as in white, black, and occasionally purple, is found in the Ming dragon screens of Peking and Tatung, Shansi.

HISTORY AND DEVELOPMENT

Prehistoric Wares.—Unknown before the archaeological work begun in the 1920's, remains of many types of red, black, gray, and white earthenware have since been discovered in all parts of northern China from Chinghai to Manchuria. To Western scholars the most dramatic find is the *Yang-shao* pottery (with the related *P'an Shan* and *Ma-chang* groups), tentatively dated 3500–3000 B.C. Typical examples of this ware are the large buff or reddish burial jars and storage pots, made by coil and paddle and often rapidly turned (perhaps wheel-made), and painted in red and black with formal religious symbols, plus occasional naturalistic symbols such as cowrie shells. On some of the jar covers human heads are modeled. The *Yang-shao* wares compare favorably with similar neolithic pottery of Susa in Iran, Anau in Turkmenia, Tripolje (Tripolye, Komsomolye) southeast of Kiev, and the Indus Valley, and with the Pueblo pottery of the American Southwest.

Also of great importance are the black and gray groups, such as those found at Ch'eng-tzu Yai, near Tsinan, Shantung. These are related in some instances to the *Yang-shao* types, but more frequently than the latter exhibit recognizable Chinese bronze forms—for example, the hollow-legged tripods (*li*) and stem cups (*tou*). Corded paddle marks are typical, as are clay ribbon appliqué and high-polished black slip. Some of this remarkable polished ware is only one sixteenth of an inch thick—as thin as porcelain.

Scattered finds have also been made south of the Yangtze River. Notable among them are the polished black ware excavated at Liangchu, near Hangchow, and the gray wares paddle marked

with repeated square, lozenge, and *f*-shaped symbols, discovered on Lamma Island, near Hong Kong. These, like many of the northern finds, are evidence of continuity of manufacture from prehistoric times. Most of the wares, both north and south, have been found in association with artifacts of stone, bronze, and other materials.

Shang and Chou Wares (1523–256 B.C.).—The most distinctive pottery of the Shang dynasty is a kaolinic white earthenware ornamented with carved cicadas, dragons, *t'ao-t'ieh* (animal-like faces), and other figures, conveying profound concepts of life, death, and immortality in the same language of symbols and in the same style as the Shang ritual bronzes. Both these and cruder gray to reddish wares (carry-overs from prehistoric types) have been uncovered in excavations undertaken by the Chinese government at Anyang, site of the Shang capital.

Certain prehistoric wares, notably the black and gray, were probably made through the Shang dynasty into the Chou period. The latter dynasty saw the development of glazed earthenware, the glaze perhaps first appearing on the vessels through a natural process, from wood ash settling on the hot clay during firing. Before the end of the Chou period, as the heat of the firing was increased through development of the kilns and through the selection of natural clays with a high kaolin content, glazed stoneware came to be produced. The protoporcelain which the American anthropologist, Berthold Laufer, so daringly postulated in 1917 as a post-Han ware, may be recognized and accepted as of pre-Han origin.

Han Wares (202 B.C.–220 A.D.).—Best known of the Han wares, and originally common north of the Yangtze and also found in Korea, was a lead-glazed earthenware, the body of which fired either gray or red, with a glaze usually of dark, opaque green, patinating through burial to a light silvery hue. The shapes are sturdy and appropriate to an essentially heavy ware. The ornaments, typically molded in relief, include lively hunting scenes, with mountains, trees, clouds, dragons, tigers, bears, and mounted riders. Formal symbols are also found, particularly, as on the Han bronzes, the *t'ao-t'ieh* and ring, signifying the jaws of death and the way through them. Religious and secular purposes were served by such objects as grain jars, censers with hill-shaped covers (called *po-shan lu*), ladles, candlesticks, and, for funerary use, models of towers, farms, domestic animals, and people.

There are few examples in good condition of the originally common painted Han earthenware. For this reason, the tiles with swift brush drawings of Han men and women in costume, in the Museum of Fine Arts, Boston, are of paramount interest.

The protoporcelain which Laufer found to be rare in northern China is comparatively plentiful in the south. A kaolinic stoneware with a controlled ash glaze, it bespeaks a different background and another cultural environment. Typical ornament includes "herringbone" or zoomorphic handles, wavy comb markings, and incised, bird-headed clouds. A Han kiln site excavated by Olov R. T. Janse, Swedish American archaeologist, in Annam produced wares fitting closely the cultural pattern south of the Yangtze.

Han to T'ang (220–618 A.D.).—The indigenous custom of making funerary objects persisted in the four post-Han and pre-T'ang centuries. Clay figurines called *ming chi* were

simply and admirably modeled and decorated with slip and pigment, but not glazed. Representations of musicians, maidservants, soldiers, domestic and miraculous animals, and minor deities such as personifications of the signs of the zodiac, continued to be made for burial during this period, which also saw the development for aboveground use of an entirely different school of sculpture, in stone and bronze, devoted to Buddhist iconography (see section on *Art*). Constant in style but refreshingly different in their many types, these figures are generally assigned to the Six Dynasties, particularly to the Wei period (386–556 A.D.), an age of which we have scant knowledge apart from the figures, funerary and devotional, and the notable *Yüeh* ware.

Yüeh Ware.—Thanks to investigations made by Archibald Brankston, British authority, in 1937 at an inundated kiln site at Chiuyen, near Hangchow, we know that *Yüeh*—the first great porcelainous stoneware and first true celadon, one of the most important of China's ceramic wares—was already being manufactured close to the end of Han. Through *Yüeh*, an early ceramic culture spreading from Chekiang through Fukien and Kwangtung provinces to Lamma Island and Annam is linked to early Sung. Typical from the beginning are excellent wheel-thrown shapes and a transparent, thin green glaze in perfect bond with a compact, light gray body. The product of deeply religious folk, *Yüeh* ware is rich in symbolism, the earlier sacred frog, bear, lion, sheep, *tsao-p'ieh*, fish, and sun symbols losing favor to the dragon, phoenix, parrot, tortoise, duck, butterfly, and lotus in the T'ang and early Sung periods. Objects of all sorts were made, including winepots and teapots, cups, bowls, basins, censers, candlesticks, birdseed dishes, whistles, pillows, and even tombstones. Distinctive of successive periods are reel-repeat bands and molded appliqué ornaments, bird-headed spouts, square sockets for wooden handles, and swift, needle-fine engraving, sometimes combined with very low relief.

At the great kiln sites by Shanglin Hu (a lake near Yüiyao) are found all grades of *Yüeh* ware, from coarse to delicate, evidence of flourishing activity there during and after the T'ang dynasty. Potsherds dated 978 indicate continued operation under the Sung dynasty. Others marked *Nei*, or Inner (Palace), confirm, for certain pieces at least, reservation for imperial use. Known to connoisseurs as *pi-sê yao* (secret-color ware), many pieces warrant such early descriptions as "misty autumn green," "like ice," "like jade," and "like tender lotus leaves." Simpler *Yüeh*-like wares were also made near Foochow (Minhow) and Chengtu. *Yüeh* pottery, as we have noted, was widely exported. In addition, numbers of potters, emigrating to Korea, had a great influence on the celadon of that country.

T'ang Wares (618–906 A.D.).—South of the Yangtze the green *Yüeh* ware was paramount during the T'ang dynasty, although, according to the *Ch'a-ching* (*Book of Tea*), some tea drinkers preferred a white ware from Hsingchou, Chekiang. In addition, a highly porcelainous gray ware was produced near Chingtêchen (Fouliang).

Northern China was supplied with numerous wares which are not classifiable by site. Funerary figures of people, horses, camels, pigs, ducks, and guardians were usually lead-glazed in mixed colors: yellow, green and white, and, in a few cases, blue. More meticulously modeled and frequently more pretentious than the figures of Wei,

they are an indication of the prosperity of the era.

Jars, vases, and pots of this period exhibit as robust and noble shapes as ceramic art affords. Solid but neatly beveled bases, full bodies, narrow necks, firm mouths and rims, and well-made handles are typical. White and buff earthenware glazed like the grave figurines, and white and gray stoneware bearing either transparent, feldspathic neutral or greenish glaze, or opaque gray, white, black, and brown glaze, are characteristic.

In one type of ware the black or brown glaze is relieved by large milky blue splashes. In nearly all wares the body clay and glaze were generously used, and often the only ornament is the natural running of the glaze. Ornate medallion and appliqué pieces reflect the existence also of cosmopolitan and exotic taste. A marbled ware of brown and white clays, cleverly kneaded to produce different patterns and usually bearing a neutral transparent glaze, was also made. Buddhist emblems, particularly the lotus, were in constant use.

Wares of the Five Dynasties (907–960 A.D.).—During this period the most famous wares were *Yüeh* in the south and *Ch'ai* in the north, the former flourishing under the patronage of the Wu-Yüeh princes, the latter under a single emperor of the Later Chou dynasty, Shih Tsung (r. 954–959). Of *Ch'ai*, said to have been made at Chenghsien (formerly Chengchow) in Honan, little is known beyond the tantalizing description, "blue as the sky after rain."

Sung Wares (960–1279 A.D.).—Heirs to the soundest of pottery traditions and to all the secrets of the T'ang period, the master potters of the Sung dynasty developed a number of wares that have never been equaled. Their success depended on the exploitation of the natural properties of clay and the natural effects of firing, as well as on rare manual skill, an eye for subtle proportion, and sound knowledge of practical use and of sophisticated symbolism.

Despite the fame of the specific wares cited in the paragraphs which follow, hundreds of other wares are still unknown or unidentifiable. The general standards were so high that the mere designation of a pot as *Sung-tz'u* (Sung ceramics) is considered praise enough among potters.

Lung-ch'üan.—Celadon from Lungch'üan (Dragon Springs), southern Chekiang, gradually supplanted *Yüeh*. This *Lung-ch'üan* ware has a dark to light gray or white body and a glaze varying from many rich green and bluish green hues (*clair de lune*, sea green, and others) to extremes of gray and straw color. The glaze may be clear and transparent, with scattered bubbles, or dully translucent; it varies to the touch (an important consideration in Chinese use and connoisseurship) from smooth and glassy to unctuous ("like congealed lard"), and tends to run or gather attractively. Normally the specimens are heavy, with incised, carved, or appliqué ornament, and show a natural crackle or craze which darkens with age. Censers, large vases, plates, and rice bowls are most typical.

Two rare types of *Lung-ch'üan* attributed to the Chang brothers, *Ko* for the elder, and *Chang*, or *kinuta* (as the Japanese call it), for the younger, were intentionally cracked and smooth uncracked, respectively. Occasional brown-spotted *Lung-ch'üan* pieces are called by the Japanese term *tobi seiji*. The *Lung-ch'üan* body typically burns red when exposed—hence the term "iron foot" for unglazed bases.

"Northern Celadon" and *Ju*.—Similar to *Lung-ch'üan*, but perhaps more plebeian, is the ware known by the term "northern celadon," much of which is made in exquisite molds. It comes from Honan, which also produced the famous *Ju*, a much-disputed collector's item.

Kuan.—Two official celadons, both with controlled crackle, were northern *Kuan*, made at Kaifeng, of which there are few genuine specimens, and southern *Kuan*, made after 1135, when the Southern Sung capital was established in Hangchow. Kiln sites in that city reveal an unrivaled ware of astonishing thinness of body, thickness of glaze, and subtlety of potting, obviously catering to imperial taste. The body may be white but frequently is very dark; the glaze covers a wide range of soft grays, blue grays, and greens, and, rarely, straw color. Objects were sometimes ground down after biscuit firing and fired several times in order to increase the thickness of glaze and the size of crackle spacing.

Ting.—The famous white *Ting* ware made at Chientz'uts'un and Yenshants'un near Tingchow, Hopeh, exemplifies the usual practice of Sung potteries; it was produced in various grades from coarse to fine in order to meet different uses and different pocketbooks. The poorest peasant in Sung China could afford wares that are priceless today. *Pai Ting* is a creamy white translucent and resonant porcelain; *fên Ting* is grayer and sturdier; *T'u Ting* is frankly heavier, with a dark gray body dipped in white slip and a transparent glaze. The ware lent itself to the most delicate linear and comb-marked floral symbols, ducks, and reeds. Of the two kiln sites investigated by Fujio Koyama of Tokyo in 1941, Chientz'uts'un evidently produced the more sophisticated products, while Yenshants'un seems to have specialized in coarser wares. Besides the white ware, fine black and brown shards found by Koyama at the former site together with fragments of white-rimmed black bowls at the latter, have greatly expanded the general concept of the term *Ting*. These finds at once dramatically undermine the long-accepted Western term "Honan *temmoku*" and confirm Chinese tradition with respect to black *Ting* and red *Ting*.

The name *Ting* was associated with similar Kiangsi wares, nicknamed *nan* (southern) *Ting*. White and off-white porcelain types were found by Brankston near Chingtéchen (Fouliang) and at the Yungho site near Luling (formerly Kian or Chian). Much of the northern ware, especially *t'u Ting*, has been excavated at Chulühsien, a former market town on the Grand Canal, wiped out by a flood in 1108.

Tz'ü-chou.—Also recovered from Chulühsien were many examples of *Tz'ü-chou* (porcelain prefecture) ware, made at the nearby town of that name in Hopeh, in which white and brown to black slip and glaze were variously combined with white and buff body clays. Techniques include carving through one clay, light or dark, to reveal another, both being covered with transparent glaze. The underglaze brown painting—bamboo sprigs, vines, peonies, lotuses, birds, and animals—is akin to the brushwork of the great Sung painters. Storage jars, tall-necked vases, and pillows are well-known types of this ware. Occasional examples were covered with a transparent strong blue glaze. Rare though generally poor examples of late Sung to Yüan ware bear overglaze enamel painting in red, green, and yellow. The brown-and-white stock-in-trade ware

has been manufactured continuously down to modern times.

Chün.—From Chünchou (now Yuchow) came *Chün* ware in two grades, not always readily distinguishable: *ts'ü-t'ai* (porcelain body); and *sha-t'ai* (sandy or coarse body), the glaze of which is typically an opaque robin's-egg blue, plain or marked with crimson, pink, or strawberry splashes. Many other variations, including purple and gray green, are known in this glaze, which is usually thick, sometimes streaked, and may exhibit an "orange-peel" or "chicken-skin" texture on the surface, or equally admired "earthworm tracks"—vestiges of cracks in congealing immature glaze. Too garish for most Chinese, the ware is the pride of many a collector and the despair of many a potter who would copy it. Flowerpots numbered according to size, bulb bowls, censers, vases, and rice bowls are typical products.

Ying-ch'ing.—In the Chingtéchen area the *ying-ch'ing* (shadowy blue) porcelain was made like *Ting* in thinness and ornament, but with a more granular body and a glassier glaze. Both freehand and molded ornament were employed, as in *Ting*, for bowls and saucers, often silver rimmed, and for many other objects. The color range includes gray and white.

Chien.—One of the wares most renowned among the tea drinkers of China and Japan, and one of the humblest, was *Chien*. This ware is known also by the Japanese name *temmoku*, through association with a single bowl brought to Japan from the sacred Buddhist mountain, Tienmu Shan, in Chekiang. It was made near the village of Shuichi in northern Fukien. Manufactured in tea-growing hills, it was a simple local product that found favor and fame abroad. It has a porous gray to black body and a glaze that may be plain black or brown, or may show streaked effects over black, called "hare's fur," "partridge feather," or "oil spot," gathering in a thick welt or "tear drops" short of the base. Even in Sung it was imitated at the Yungho kilns near Luling, where ornament was added by brush, leaf, or stencil. Kiangsi *temmoku* is the name of this brown-glazed white-bodied ware. "Northern *temmoku*" is the accepted Western term for various black and brown wares of Honan and Hopeh, in which white and buff bodies and painted ornament (brown over black), and "oil-spot" effects are usual. Heavy specimens are sometimes attributed to *Tz'ü-chou*; lighter plain examples have been identified as red and black *Ting*.

Yüan Wares (1260-1368 A.D.).—The invasion of the Mongols and establishment of the Yüan dynasty had little effect on the potter's art in China, and most of the Sung wares continued in production. The *shu-fu* palace ware, a faintly bluish white porcelain, was made only in Yüan. Of importance to ceramics outside of China was a visit of King Rama Kamheng of Siam (now Thailand) to Kublai Khan, the first Mongol occupant of the Dragon Throne. One of the results of this visit was the emigration of several hundred potters to Siam. Informal excavations at Savargalok (Sawankhalok) and Sukhodaya (Sukhothai) show obvious Chinese influence, particularly in the celadons. See also THAILAND.

Ming Wares (1368-1644 A.D.).—Under the patronage of the Ming emperors the long-maturing porcelain tradition received tremendous impetus. With inexhaustible supplies of the essential elements for porcelain manufacture—kaolin (China clay), and petuntse (China stone)—at hand, a

with a slow awing in popular taste to white porcelain, the wares of Ching-t'chen and lesser sites soon overshadowed the finest Sung wares. Unfortunately, the rejection of gray clays eliminated one of the important visual effects of so many of the Sung wares, that of toning down the color of the glazes over them. What some ancient and modern authorities might hold to be impurities in the dark clays of Sung (for example, presence of iron in *Lung-ch'üan* and *Chien*) were often the source of the color of the glaze itself. "Purification" of the body and glaze left white wares that could be developed as white monochromes, or as white wares decorated by adding color.

Some Sung wares continued to flourish, notably the solid, durable celadon made at Lungch'üan and, as time went on, at other places in the district. A number of examples which can be identified as Yüan, Ming, or even Ch'ing are nevertheless in the direct Sung tradition. Many others have careless or novel shapes, whiter bodies, and thinner, weaker greens, and fall away from the old standards. Often conscious reconstructions of Sung types were made, with effects such as that obtained by simulating in brushwork the natural "iron foot" of Sung.

T'z'u-chou ware had a history similar to that of *Lung-ch'üan*. The tradition lived on, although old secrets were sometimes forgotten in following new trends. The ornament tended to become more meticulous, so that both the slapdash boldness and the finesse of the earlier ornaments and shapes were too often lost. Some excellent embellishment in two or more shades of brown is found in *T'z'u-chou* Yüan and Ming ware dynasties.

Ming White Wares.—White monochrome porcelains, mentioned by such travelers as the Arab Ibn-Batuta (q.v., traveled 1325-1349), have been manufactured in one place or another continuously into the 20th century. A collection of white wares alone would be of great interest and variety. Rarest and finest of the Ming white wares was that made for imperial use during the Yung-lo period (1403-1424), and known because of its thinness as *t'o-t'ai* (bodiless) or "eggshell" porcelain. Unless the object is held to the light, the decoration is unnoticeable.

Also famous in Ming times, and remarkable for its continuation with little or no change, is the white *Tê-hua* made in the village of that name. Known alternatively as *Hinghua* (after Hsinghua) ware and (white) *Chien* ware (not to be confused with Sung *Chien*), it became very popular with early European collectors. Many of the finest specimens, known as *blanc de chine*, are found in France. In addition to all sorts of household utensils and scholars' desk pieces such as brush holders, the ware is famous for admirably modeled figures. These include Buddhist images of Kuan-yin (Goddess of Mercy), Kuan Lao-yeh (God of War), and Mi-lo-fo (Maitreya), and Taoist images of the *pa hsien* (Eight Immortals), all in sizes to fit household shrines. Temple paraphernalia was also made—three-legged incense burners, vases in the shape of the sacred double gourd, and traditional decorative objects, such as imitation rhinoceros-horn cups ornamented with plum blossoms. These items are of a smooth, milky or ivory white, thin or thick, heavy or delicate, solid or hollow according to requirement, but always of high-grade porcelain.

Ming Blue-and-White Wares.—Blue-and-white porcelain, which was known in the Yüan period probably as early as Sung, in time rivaled,

and finally overtook, celadon as the standard household ware throughout China. Special interest was shown by the Ming emperors, who, one after another beginning with the Hung-wu reign (1368-1398), patronized Ching-t'chen. Specimens attributed to this first reign must be accepted with reserve, but collectors are on safer ground with respect to the famous blue and whites of the Yung-lo (1403-1424), Hsuan-tê (1426-1435), Ch'eng-hua (1465-1487), Hung-chih (1488-1505), and later reigns.

The blue employed for underglaze decoration is cobalt oxide, a mineral that must be ground to a fine powder and mixed with water before application with the brush. A small amount goes a long way, and painting on the thirsty clay body requires speed and control. The Yung-lo blues are very dark ("deep kingfisher" to smoky black), with a tendency to drift attractively like wisps of smoke into the clear glaze. This blue was undoubtedly the *su-ni-p'o ch'ing* (Mohammedan blue) said to have been imported from Iran. Careful firing is essential. The clear, deep quality of the Hsuan-tê blues set a standard for later periods. The native color, dull gray blue to blue black—not without an appeal of its own—is easy to distinguish. It is found in all the blue-and-white wares of the Wan-li reign (1573-1620) and of other times when foreign imports were cut off.

The ornament in blue and white is always more detailed and elaborate and often more labored than that of Sung wares, but it has the same, never-failing symbolic purpose. Flowers, vines, fish, legendary scenes, and (on the imperial pieces) five-clawed dragons abound.

Canton and Ching-t'chen were the chief of many centers of manufacture of blue-and-white ware. Malcolm Farley, American missionary and archaeologist, found evidence of it, surprisingly, at Têhua in 1935.

Ming Yellow Ware.—Imperial Ming yellow of the Hsuan-tê, Ch'eng-hua, Cheng-tê (1506-1521), and Chia-ching (1522-1566) reign periods is the most famous of the Ming monochromes. It is a white porcelain to which a coat of yellow glaze was applied over a colorless glaze before firing, with the underside left white, and bearing in Mohammedan blue the reign name enclosed in a double circle. The yellow, near lemon but never greenish, is the symbolic color of the Son of Heaven, the color of the sun, the source of life-giving power brought down to earth in the person of the emperor.

Other Ming Monochromes.—Comparatively rare, these include black, copper red and iron red, cobalt blue, aubergine, and apple green. The last named was used over a cracked glaze.

Ming Polychromes.—*San-ts'ai* (three color) is the name given to handsome, heavy pots decorated in low-fired glazes laid on rather crudely in areas outlined in threads of clay. The technique is like that used in cloisonné. This is the Ming development of the Han-T'ang lead-glaze tradition. Green, yellow, aubergine, dark blue, turquoise, and transparent (for white) are the colors employed, often more than three at once.

Wu-ts'ai (five color) is an elastic term for many-colored enameled wares too numerous to describe in detail. As the Ming dynasty advanced, the potters tended to develop more and more mixtures and arrangements of colors, including gold, and more and more clever technical devices, so that the resulting objects call to mind a flower garden, a piece of embroidery, or a

in cloisonné, obliterating all suggestion of the potter's art, which is always there underneath. Even the most gaudy specimens, however, are documents of a superb and flourishing culture. The elements of the aesthetically dazzling ornaments are always meaningful symbols.

Earthenware.—Earthenware objects for garden, desk, tea table, and nursery were manufactured from the 16th century on at Ihsing (Yih-sing), in Kiangsu, and Fashan (Fatshan or Namhoi), near Canton. The significance of these wares, glazed sparingly if at all, is that they thrived in the heyday of brilliant glazes, relying for their color appeal on the polished surfaces of common black, brown, and yellow clays.

Ch'ing Wares (1644–1912 A.D.).—The Manchus, succeeding a native dynasty, followed the splendid precedent of the Mongols in maintaining the cultural traditions of the country they had conquered. Almost every ceramic ware of Ming had a successor, and nearly every ware of Sung was copied. It was a prolific era, in which craftsmen became increasingly involved in mass production and catered to a rising popular demand for curiosities. Modern potters rightly marvel at the technical achievements of Ch'ing. This was the age which produced, with equal virtuosity, tiny snuff bottles and porcelain vases large enough to hold a man.

Certain remarkable developments were encouraged by imperial patronage, particularly during the three great reigns of K'ang-hsi (1662–1722), Yung-ch'eng (1723–1735) and Ch'ien-lung (1736–1796). From the K'ang-hsi period come the finest oxblood or "crushed ruby red" *Lang-yao* and the related peach bloom, as well as apple green, mirror black, and many other monochromes. Ordinary ginger jars, decorated with well-drawn *Prunus* blossoms against a crudely painted, solid cobalt background, brought ridiculous prices in the West. Other curious fads of the 18th and 19th century European collectors were the clumsy and gaudy vases grouped under their predominating color: *famille verte*, *famille rose*, and *famille noire*. Chinese and Japanese collectors, enjoying color in smaller amounts, have preferred "tea-dust" glaze, in as many subtle hues as the flavors of the tea leaf.

In the painted ornament of household wares, in which blue and white predominate, is found, in addition to the familiar decorative symbols, a mine of folklore material. Pretty scenes and popular tales veil a wealth of metaphysical content. In the so-called love-chase pattern, for example, in which the huntsman, riding with his beloved on one horse and shooting downward, slays a rabbit, two symbols of the flesh are involved. The lower symbol (the rabbit standing for carnality) is destroyed through the hunter's aim and through the balance maintained in the higher symbol (the horse standing for the flesh as vehicle).

Modern Wares.—In modern China, ceramic wares of all kinds are made in every province, with Fouliang (Ching-t'chen) still holding the leadership. Obtainable in the open market are temple images and censers, toys and desk ornaments, vases, wine jars, pillows, deep oval Soochow (Wuhsien) bathtubs, fertilizer cisterns, cups, bowls, soup spoons, and fish plates—all evidence that Chinese ceramic traditions are still very much alive.

CHINA, Great Wall of, the largest artificial defense structure in the world, a barrier extending for about 1,250 miles (with its branches, about 2,000 miles) in northern China Proper, of which it forms in part the boundary. Its western end is in the deserts of Central Asia; its eastern end reaches the sea northeast of Peking. There is also an extension to the Sungari River to the northeast. The wall was erected as a barrier against the inroads of barbarian tribes, and a portion of it dates from about 214 B.C., during the Ch'in dynasty. The greater part, however, was built in the latter half of the 14th century, during the Yuan dynasty. The wall is carried over height and hollow, without regard to topography, and in one place is at a height of more than 5,000 feet above sea level. Earth, gravel, brick and stone were used in its construction; some parts are more substantially built than others. Its greatest height, including the parapet at the top, is about 50 feet; the average height is about 22 feet, and the width 20 feet. It is strengthened at regular intervals by 40-foot towers. See also *CHINA—History*; *CERAMICS*.

CHINA ROSE, *Rosa chinensis*, the name given to a number of varieties of garden rose chiefly derived from *Rosa Indica* and *Rosa semperflorens*, both natives of China; it is also called Bengal rose. The name is also given to *Hibiscus rosa-sinensis*, a mallow common in China and Indonesia, and an ornament in greenhouses.

CHINA SEA, that part of the Pacific Ocean bordering the coasts of China, French Indochina, and Malaya, from southernmost Japan to the end of the Malay Peninsula. Formosa and its strait divide it into a northern part, the East China Sea (or Eastern Sea), and a southern, the South China Sea. The term "China Sea," however, is often restricted to the area of the South China Sea. The East China Sea, smaller of the two parts, is enclosed on the north by the Yellow Sea and Korea; east, by Kyushu and the Ryukyu Islands; south, by the southern Ryukyus and Formosa; west, by China. The northern limits of the South China Sea are formed by China's Kwangtung Province and Formosa; eastern, by the Philippine Islands; southern, by Borneo; and western, by the Malay Peninsula and Indochina.

CHINA-UNITED STATES DIPLOMATIC RELATIONS. There is an old story, long discredited, that a Chinese Buddhist priest discovered North America in the 5th century of the Christian era. So far as is known no Chinese set foot in the New World until long after the Columbian discovery. Sino-American relations virtually started when the Spanish and Portuguese began introducing American plants, American minted dollars, and even the *morbus americanus* (syphilis), to all parts of the world.

On the Atlantic coast of North America interest in China was hardly reflected until the 18th century when *chinoiserie*, an echo of the fads which were sweeping over Europe, began to touch a few homes. Of all Chinese products tea was most in demand, imported to the British

colonies in British ships. After the famous Tea Act of 1773 and the Revolutionary War, American merchants, prevented from trading with the British West Indies, were forced to seek their fortunes farther afield, and set out directly for the East.

The first American ship to reach China (on Aug. 28, 1784) was the *Empress of China*, loaded chiefly with ginseng. It made the round trip from New York to Canton in 15 months. Its return cargo, mainly tea, made a profit of 25 per cent. This successful venture prompted other shipowners in Salem, Boston, Providence, New York, Philadelphia, and Baltimore to enter the China trade. The supercargo of the *Empress*, Samuel Shaw, was appointed first American consul at Canton in 1786 to watch over this trade, and continued in office, without salary, until his death in 1794. His position was not recognized by the Manchu government, but it tolerated his presence and threw less difficulties in his way than did the British, who slighted him on his second voyage. The Chinese people, a few of whom were acquainted with the main facts of the American Revolution, first called the United States the New Nation, changed later to *Hua ch'i kuo* (Flowery Flag Nation) after the stars of the new emblem.

During the early decades, the American traders were confined, like all other Occidentals then coming by sea, to the single port of Canton, and were bound by certain regulations. They obeyed the rules fairly well, although like the rest they indulged in the illicit trade in opium, picked up as a cash cargo en route to China. In 1821 an American called Terranova, in the good ship *Emily*, which was known to be engaged in smuggling opium, was accused of accidentally killing a Chinese woman. The Manchu government demanded that he be turned over to the local court of justice, and the Americans yielded, although they were sharply criticized for so doing by the British.

By 1839 troubles over opium smuggling and other matters had reached such a pitch that war between the British and the Manchus was inevitable. Although the United States took no part in this affair, American businessmen gained much from the privileges wrung in 1842 by the British through the Treaty of Nanking. By this treaty Canton and four other ports—Amoy, Foochow (now Minhow), Ningpo (now Ninghsien), and Shanghai—were opened to trade and residence (including missionary activity), consuls were permitted to establish offices at all five places, a low tariff on all imports and exports was promised (this was an encroachment on China's sovereignty), and a measure of extraterritoriality stipulated (another encroachment).

Two years later the newly appointed United States commissioner to China, Caleb Cushing, negotiated the Treaty of Wanghia (ratified by both Manchu and United States governments in 1845). He had endeavored to undertake the negotiations at Peking, the capital, but was prevented from doing so by the insistence of the Manchu commissioner. His treaty—of 34 articles as compared with Sir Henry Pottinger's 13—provided for the same privileges and concessions as the British, together with four significant additions: Americans engaging in opium smuggling would receive no protection from the United States; revision of the treaty would be permitted at the end of 12 years; officers and citizens of

the United States would have the right to purchase books and to employ Chinese scholars for the study of the languages of the empire; and the article on extraterritorial jurisdiction was more definitely stated.

It read in part as follows: "... and citizens of the United States who may commit any crime in China shall be subject to be tried and punished by the Consul, or other public functionary of the United States, thereto authorized, according to the laws of the United States." Cushing also inserted a joker in the treaty, the so-called favored nation clause, which read: "And if additional advantages or privileges, of whatever description, be conceded by China to any other nation, the United States, and the citizens thereof, shall be entitled thereupon to a complete, equal, and impartial participation in the same." In the Chinese text he called the North American continent *A-mei-li-chia kuo*, generally shortened to *Mei kuo* (beautiful country), a name which has stuck.

Within 12 years (1856) the United States looked to Peking for a revision of the treaty but attempts to communicate with the Manchu court were rebuffed. The British, smarting from various slights, joined by the French, made an appeal to arms, and forced their way first into Canton (1856) and then into Tientsin (1858). The Americans did not join in the fighting, but took advantage of the situation to negotiate a revision of the American treaty at the same time that the British, French, and Russians were negotiating theirs. Exchange of ratifications was arranged for the following year (1859), John Elliott Ward being sent by President James Buchanan for the purpose. The British and French were blocked because they insisted on going their own way to Peking. The Russians had no difficulty as they went overland, while Ward followed the instructions of the government and was borne in state to the capital. As he refused to kowtow to the emperor, he was obliged to return to Pehtang (Peitang) for the ratifications. This treaty provided for the opening of more ports to trade and residence, the right of direct correspondence with the imperial government, and the right of missionaries to practice and teach religion. It also contained this clause, subsequently to be recalled by the Chinese, particularly in 1919 at Paris:

"If any other nation should act unjustly or oppressively, the United States will exert their good offices, on being informed of the case, to bring about an amicable arrangement of the question, thus showing their friendly feelings." Americans were to share, through the favored nation clause, in the provisions later obtained by the British and French: namely, the establishment of permanent diplomatic residences in Peking, the creation by China of a foreign office which would treat with foreign nations on terms of equality, and the right to travel freely in the interior of China. An indemnity of \$735,000 for American losses sustained in the war between China and Great Britain was likewise obtained; more than half of this sum was returned by Congress in 1885 after all claims had been examined and met.

In the meanwhile the Protestant churches in the United States had become interested in China as a sphere of activity, and this interest was to exert a marked effect on American governmental policy. The churches in this respect were fol-

lowing the lead of the London Missionary Society (Congregational), which sent its first missionary, Robert Morrison, to China in 1807. As a matter of fact, the British East India Company would not let Morrison travel on its ships; so he was obliged to sail to the United States and seek passage on an American clipper; he reached Canton armed with a letter from Secretary of State James Madison, addressed to United States Consul Edward Carrington.

The first American missionary body was the American Board of Commissioners for Foreign Missions, an interdenominational organization with headquarters in Boston, which later was maintained by the Congregationalists alone as other denominations formed their own societies. Its first missionary to China, sent at the instance and partly under the support of an earnest and substantial American merchant in Canton (D. W. C. Olyphant), was Elijah C. Bridgman, who arrived in 1830. An excellent student of the language and culture of China, he started and edited *The Chinese Repository*, an invaluable record of the early years of Sino-American relations. Among able successors to him were S. Wells Williams, printer, scholar, diplomat, and first professor of Chinese at Yale, who arrived at Canton in 1833; and Peter Parker, physician, interpreter, and the commissioner of the United States (to punish the recalcitrant Manchu court, he tried to occupy Formosa for the United States, but Congress would have none of it), who arrived in 1834 and opened the first missionary hospital in 1835. These and many other missionaries became a large fraction of the United States citizenry in China. (In the 1870's a census showed 500 Americans, of whom 200 were missionaries.) They had the most intimate dealings with the Chinese, learned their language best, and were in the forefront in efforts to evangelize them, and provide them with both the material and nonmaterial benefits of American culture. Similarly their writings and lectures about China and the Chinese were for a century the principal source of information to the people of their own homeland. Toward the end of the 19th century a few Americans were scattered among the Roman Catholic societies (founded in Europe) working in China, but not until World War I dried up the usual sources of funds was an American Catholic society founded to send out missionaries direct.

Among the men of adventure from the United States who have gone to China, first place should possibly go to Frederick T. Ward (1831-1862), a native of Salem, Mass. After an inconspicuous life as a sailor in and out of Shanghai from 1851 to 1859, he was arrested by the United States consul in Shanghai for violating the neutrality of the United States by offering to aid the imperial army fighting the Taiping rebels. He broke away and for the next three years organized, drilled, and led a motley body of troops against the rebels in the neighborhood of Shanghai. So successful was he that the Manchus made him a colonel, the British and United States governments came to his support, and on his death posthumous honors were granted by the court and a library was erected in his memory at Salem.

The first United States minister to reside in Peking was Anson Burlingame. He liked Chinese, sympathized with the government, aided it in its problems. In 1867, when Mr.

(later Sir) Robert Hart of the British Inspectorate General of the Customs proposed that a mission be sent abroad to negotiate more favorable treaties and to arrange for legations in Western capitals. Burlingame agreed to be chief of the mission. Assisted by one Manchu and one Chinese, the mission visited the United States, Great Britain, France, Germany, and Russia, but broke up on the premature death of its leader in St. Petersburg in 1870. It had been greeted with some skepticism, but undoubtedly brought about useful results. In Washington, Burlingame negotiated a new treaty, the principal articles of which recognized China's right to regulate her own internal trade, provided for the opening of consulates in the United States, recognized the "right of man to change his home and allegiance" and "the mutual advantages of free migration and immigration," and declared that "Chinese subjects visiting or residing in the United States shall enjoy the same privileges, immunities and exemptions in respect to travel or residence as may be enjoyed by the citizens or subjects of the most favored nation."

For the United States it was standard practice to recognize the inherent right of man to change his home and allegiance. For China the reverse was true; for centuries the people of China had been forbidden to go abroad. Hardly had this treaty been signed (1868) when agitation against Chinese immigration to the United States began. In 1870 there were 62,376 Chinese, mostly laborers, in the United States. They began to come at the time of the California gold rush and later were employed in large gangs in the construction of transcontinental railway lines. As long as there was a labor shortage all went well; when construction ceased, the Chinese were legislated against, mobbed, and maltreated. A congressional commission reported on the situation in 1877, and Congress passed a bill forbidding their immigration in 1879. President Rutherford B. Hayes properly vetoed this as violating the Burlingame treaty.

James B. Angell, president of the University of Michigan, was then asked to go to Peking to arrange if possible for a modification of the treaty. In this he was successful, the Manchu court agreeing "that the Government of the United States may regulate, limit, or suspend such coming or residence, but may not absolutely prohibit it." Congress in 1882 then suspended the immigration for 10 years. By this time there were about 105,000 Chinese in the country and the leaders of the anti-Chinese agitation clamored against the legislation. The question became a political football until about the turn of the century, when the exclusion of Chinese, except for temporary residence by certain classes, was enacted. The Chinese were deeply offended by this act, as were the friends of China. Actually, however, the removal of the question from the political arena, the cessation of the stump speeches and scurrilous attacks of all sorts, made life for the Chinese in the United States more bearable again. Nevertheless their number dwindled until in 1940 only 37,242 were recorded. By this time the gallantry of the Chinese people in their fight for freedom and the genuine esteem of millions of Americans for their qualities of frugality, orderliness, and hard work resulted in a new attitude. On Dec. 17, 1943 the exclusion laws were repealed, immigration was put on a quota basis, and Chinese became eligible for naturalization.

By the last decade of the 19th century events in eastern Asia seemed to be rushing inexorably toward a partition of China. Japan won an easy victory in the war of 1894-1895, demonstrating China's defenselessness. Russia, France, Germany, Great Britain, and Japan moved in for the kill. With the annexation of the Philippine Islands the interest of the United States in developments across the Pacific mounted. To ensure American participation in the markets of a China free from entanglements, the United States government—historically insistent on having the same rights in China as any other nation—proposed (1899) to the powers the policy of the Open Door. Though the proposal met with a chilling response, Secretary of State John Hay announced that from henceforth all were agreed on equality of opportunity and the maintenance of the territorial integrity and autonomy of China. Even as the United States prepared to join in the anti-Boxer expedition in the summer of 1900, Hay declared that the American objective was "to seek a solution which may bring about permanent safety and peace to China, preserve Chinese territorial and administrative entity, protect all rights guaranteed to friendly powers by treaty and international law, and safeguard for the world the principle of equal and impartial trade with all parts of the Chinese Empire."
